} TelSpcPlayDTMFType
```

#### Field Descriptions

- `keyTone` The keycode of the key tone to play. This must be one of the [Keycode Constants](#).
- `duration` The duration of the tone, specified as a multiple of ten milliseconds.

## Telephony Calls Functions

This section describes the functions used with the telephony calls service sets portion of the telephony API.

### TelDtcCallNumber Function

**Purpose** Initiate a data telephone call.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelDtcCallNumber(UInt16 iRefnum,
    TelAppID iAppId,
    TelDtcCallNumberType *ioParamP,
    UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelDtcCallNumberType](#) structure that specifies information about the telephone call.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelDtcCallNumberType</a> structure passed to this function in the <code>ioDataCallParamP</code> parameter.
<code>functionId</code>	<code>kTelDtcCallNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioDataCallParamP` remains in memory until the asynchronous call completes.

---

**Comments**

Call this function to start a data telephone call.

Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelDtcCloseLine\(\)](#)

## TelDtcCloseLine Function

<b>Purpose</b>	Hang up a data line.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelDtcCloseLine(UInt16 iRefnum,                     TelAppID iAppId, UInt8 iLineId,                     UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>→ <i>iLineId</i> The ID of the line to hang up. This is the ID returned by a previous call to the <a href="#">TelDtcCallNumber()</a> function.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td>Points to the unsigned integer value passed to this function in the <code>iLineId</code> parameter.</td></tr><tr><td><code>functionId</code></td><td><code>kTelDtcCloseLineMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iLineId</code> parameter.	<code>functionId</code>	<code>kTelDtcCloseLineMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iLineId</code> parameter.								
<code>functionId</code>	<code>kTelDtcCloseLineMessage</code>								
<b>Comments</b>	<p>Call this function to end a data telephone call.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsDtcServiceAvailable()</a> macro.</p>								

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCallNumber\(\)](#)

## TelDtcReceiveData Function

**Purpose** Receive data on an opened data communications line.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelDtcReceiveData (UInt16 iRefnum,
    TelAppID iAppId,
    TelDtcReceiveDataType *ioParamP,
    UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- ↔ *ioParamP*  
A pointer to a [TelDtcReceiveDataType](#) structure.
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.

## Telephony Calls

### *TelDtcSendData*

---

paramP	Points to the <a href="#">TelDtcReceiveDataType</a> structure passed to this function in the ioRcvDataP parameter.
functionId	kTelDtcReceiveDataMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** Call this function to receive data during an active data telephone call.

Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCallNumber\(\)](#), [TelDtcCloseLine\(\)](#), [TelDtcSendData\(\)](#)

## TelDtcSendData Function

**Purpose** Send data on an opened data line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelDtcSendData(UInt16 iRefnum,  
TelAppID iAppId, TelDtcSendDataType *iParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iParamP*  
A pointer to a [TelDtcSendDataType](#) structure that specifies the data to send.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`            The transaction ID of the operation.

`paramP`            Points to the [TelDtcSendDataType](#) structure passed to this function in the `iSendDataP` parameter.

`functionId`        `kTelDtcSendDataMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments**

Call this function to send data during an active data telephone call. Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelDtcCallNumber\(\)](#), [TelDtcCloseLine\(\)](#),  
[TelDtcReceiveData\(\)](#)

## Telephony Calls

### *TelEmcCall*

---

## TelEmcCall Function

<b>Purpose</b>	Call the currently selected emergency service.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelEmcCall(UInt16 iRefnum, TelAppID iAppId,                UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td>A NULL pointer.</td></tr><tr><td><code>functionId</code></td><td><code>kTelEmcCallMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	A NULL pointer.	<code>functionId</code>	<code>kTelEmcCallMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	A NULL pointer.								
<code>functionId</code>	<code>kTelEmcCallMessage</code>								
<b>Comments</b>	<p>This function calls the telephone number specified in a previous call to the <a href="#">TelEmcSelectNumber()</a> function. In synchronous mode, this function returns after the dial command has been sent to the phone.</p> <p>After calling this function, sub-launched applications can receive notifications when the following telephony events occur. Note that these notifications can be raised after both synchronous and asynchronous calls to this function.</p>								

Event	Description
sysTelSpcLaunchCmdCallReleased	Warns that the telephone call has been released.
sysTelSpcLaunchCmdCallBusy	Warns that the called equipment is busy.
sysTelSpcLaunchCmdCallConnect	Warns that the line is open. The ID of the open line is stored in the UInt32 value of the parameter block passed to the application.
sysTelSpcLaunchCmdCallError	Warns that an error occurred while attempting to complete the telephone call.

Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcCloseLine\(\)](#),

## TelEmcCloseLine Function

**Purpose** Close the line that is currently opened for an emergency telephone call.

**Declared In** TelephonyMgr.h

**Prototype** Err TelEmcCloseLine(UInt16 iRefnum,  
TelAppID iAppId, UInt16 \*ioTransIdP)

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points

## Telephony Calls

### *TelEmcGetNumber*

---

to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	A NULL pointer.
<code>functionId</code>	<code>kTelDtcCloseLineMessage</code>

**Comments**

Call this function to end an emergency telephone call.

Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelEmcCall\(\)](#)

## TelEmcGetNumber Function

**Purpose**

Retrieve an emergency dial telephone number.

**Declared In**

`TelephonyMgr.h`

**Prototype**

```
Err TelEmcGetNumber(UInt16 iRefnum,
                    TelAppID iAppId,
                    TelEmcGetNumberType *ioParamP,
                    UInt16 *ioTransIdP)
```

**Parameters**

→ *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelEmcGetNumberType](#) structure in which you assign the index of the telephone number that you want to retrieve.

On input, the `size` field of this structure specifies the allocated size of the `value` buffer. Upon return, the `size` field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelEmcGetNumberType</a> structure passed to this function in the <code>ioGetNumberP</code> parameter.
<code>functionId</code>	<code>kTelEmcGetNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments**

The emergency call telephone number is stored into the `value` field of the [TelEmcGetNumberType](#) structure referenced by `ioGetNumberP`. If the `value` buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the

## Telephony Calls

### *TelEmcGetNumberCount*

---

`telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumberCount\(\)](#), [TelEmcSetNumber\(\)](#), [TelEmcSelectNumber\(\)](#)

## TelEmcGetNumberCount Function

**Purpose** Retrieve the count of emergency dial telephone numbers.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelEmcGetNumberCount(UInt16 iRefnum,  
TelAppID iAppId, UInt8 *oCountP,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- ← *oCountP*  
Upon return, the total number of emergency call numbers available.
- ↔ *ioTransIdP*  
Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to unsigned integer passed to this function in the oCountP parameter.
functionId	kTelEmcGetNumberMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oCountP remains in memory until the asynchronous call completes.

---

**Comments** The emergency telephone call number is stored into the value field of the [TelEmcGetNumberType](#) structure referenced by ioGetNumberP. If the value buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the telErrBufferSize error. The size field of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumber\(\)](#), [TelEmcSetNumber\(\)](#), [TelEmcSelectNumber\(\)](#)

## TelEmcSelectNumber Function

**Purpose** Select the current emergency telephone number. This is the telephone number that gets dialed when you call the [TelEmcCall\(\)](#) function.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelEmcSelectNumber(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iIndex,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iIndex*  
The zero-based index of the emergency telephone number that you want selected.
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iIndex</code> parameter.
<code>functionId</code>	<code>kTelEmcSelectNumberMessage</code>

<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsEmcServiceAvailable()</a> macro.
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelEmcCall()</a> , <a href="#">TelEmcGetNumber()</a> , <a href="#">TelEmcGetNumberCount()</a> , <a href="#">TelEmcSetNumber()</a>

## TelEmcSetNumber Function

<b>Purpose</b>	Set the telephone number for the specified emergency dial number.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelEmcSetNumber(UInt16 iRefnum,                     TelAppID iAppId, TelEmcSetNumberType *iParamP,                     UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>→ <i>iParamP</i> A pointer to a <a href="#">TelEmcSetNumberType</a> structure that specifies the telephone number.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:

## Telephony Calls

### *TelSpcAcceptCall*

---

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the <a href="#">TelEmcSetNumberType</a> structure passed to this function in the iNumberP parameter.
functionId	kTelEmcSetNumberMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by iParamP remains in memory until the asynchronous call completes.

---

**Comments** Call this function to associate a new telephone number with the emergency dial number that has the specified iIndex.  
Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumber\(\)](#),

## TelSpcAcceptCall Function

**Purpose** Accept an incoming voice telephone call.

**Declared In** TelephonyMgr.h

**Prototype**

```
Err TelSpcAcceptCall (UInt16 iRefnum,
    TelAppID iAppId, UInt8 *oLineIdP,
    UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- ← *oLineIdP*  
A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer passed to this function in the <code>oLineIdP</code> parameter.
<code>functionId</code>	<code>kTelSpcAcceptCallMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oLineIdP` remains in memory until the asynchronous call completes.

---

**Comments**

If another line was active prior to the execution of this function, that line is put on hold. Note that there can only be one line active at any given time, and there can only be one line on hold at any given time.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelSpcGetCallerNumber\(\)](#), [TelSpcRejectCall\(\)](#)

## TelSpcCallNumber Function

**Purpose** Initiate a voice telephone call.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcCallNumber (UInt16 iRefnum,  
TelAppID iAppId, const Char *iDialNumberP,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iDialNumberP*  
A pointer to the telephone number to call.
- ↔ *ioTransIdP*  
Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the string passed to this function in the <code>iDialNumberP</code> parameter.
<code>functionId</code>	<code>kTelSpcCallNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `iDialNumberP` remains in memory until the asynchronous call completes.

---

## Comments

A successful return from a synchronous call or receipt of a successful notification from an asynchronous call does not mean that the telephone call has been connected; instead, it indicates that the dial command was sent to the phone. Successful connection of the telephone call is indicated with a sub-launch.

The dial number is formatted according to the following syntax:

---

```
DialNumber ::= <Phone_Number> | <Code_String>
              | <Phone_Number> <Code_String>

Phone_Number ::= <IntlPrefix><NatlNumber>
                 | <NatlNumber>

IntlPrefix ::= '+' <country code>

NatlNumber ::= {{Pause<Pause>}}{<Digit>}}

Code_String ::= <Symbol>{<Symbol>}

Symbol ::=      <Digit> | '#' | '*'

Digit ::=      '0' | '1' | '2' | '3' | '4'
               | '5' | '6' | '7' | '8' | '9'

Pause ::=      ','
```

---

After calling this function, sub-launched applications can receive notifications when the following telephony events occur. Note that these notifications can be raised after both synchronous and asynchronous calls to this function.

## Telephony Calls

### *TelSpcCloseLine*

---

Event	Description
<code>sysTelSpcLaunchCmdCallReleased</code>	This is passed to a sub-launched application to warn that the telephone call has been released.
<code>sysTelSpcLaunchCmdCallBusy</code>	This is passed to a sub-launched application to warn that the called equipment is busy.
<code>sysTelSpcLaunchCmdCallConnect</code>	This is passed to a sub-launched application to warn that the line is open. The ID of the open line is stored in the <code>UInt32</code> value of the parameter block passed to the application.
<code>sysTelSpcLaunchCmdCallError</code>	This is passed to a sub-launched application to warn that the telephone call encountered an error.

---

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcCloseLine\(\)](#)

## TelSpcCloseLine Function

**Purpose** Ends a voice telephone call.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcCloseLine(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iLineId,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.

→ *iLineId*

The ID of the voice line that you want to close. This is the ID returned by a previous call to the [TelSpcAcceptCall\(\)](#) function.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iLineId</code> parameter.
<code>functionId</code>	<code>kTelSpcCloseLineMessage</code>

**Comments**

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelSpcCallNumber\(\)](#)

## TelSpcConference Function

**Purpose** Initiate a conference telephone call by merging the active line and the held line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcConference (UInt16 iRefnum,  
TelAppID iAppId, UInt8 *oLineIdP,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- ← *oLineIdP*  
A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oLineIdP</code> parameter.
<code>functionId</code>	<code>kTelSpcConferenceMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oLineIdP` remains in memory until the asynchronous call completes.

---

- Comments** Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [TelSpcCallNumber\(\)](#), [TelSpcCloseLine\(\)](#), [TelSpcHoldLine\(\)](#), [TelSpcRetrieveHeldLine\(\)](#), [TelSpcSelectLine\(\)](#)

## TelSpcGetCallerNumber Function

- Purpose** Retrieve the telephone number of the caller on an incoming telephone call.
- Declared In** `TelephonyMgr.h`
- Prototype**  

```
Err TelSpcGetCallerNumber(UInt16 iRefnum,  
                           TelAppID iAppId,  
                           TelSpcGetCallerNumberType *ioParamP,  
                           UInt16 *ioTransIdP)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ↔ *ioParamP*  
A pointer to a [TelSpcGetCallerNumberType](#) structure that is used to retrieve the caller's telephone number.  
  
On input, the `size` field of this structure specifies the allocated size of the value buffer. Upon return, the `size` field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.

## Telephony Calls

### *TelSpcGetCallerNumber*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful. If there is no active incoming telephone call, this function returns the `telErrUnavailableValue` error.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSpcGetCallerNumberType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelSpcGetCallerNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The emergency telephone call number is stored into the `value` field of the [TelSpcGetCallerNumberType](#) structure referenced by `ioParamP`. If the value buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelSpcAcceptCall\(\)](#)

## TelSpcHoldLine Function

<b>Purpose</b>	Put the currently active voice line on hold.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	Err TelSpcHoldLine(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns errNone if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr> <tr> <td>transId</td><td>The transaction ID of the operation.</td></tr> <tr> <td>paramP</td><td>A NULL pointer.</td></tr> <tr> <td>functionId</td><td>kTelSpcHoldLineMessage</td></tr> </table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	kTelSpcHoldLineMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	kTelSpcHoldLineMessage								
<b>Comments</b>	<p>Note that there can only be one line active at any given time, and there can only be one line on hold at any given time.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsSpcServiceAvailable()</a> macro.</p>								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelSpcRetrieveHeldLine()</a>								

## TelSpcPlayDTMF Function

**Purpose** Play a dual-tone multi-frequency sound to the network system for a specified duration. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcPlayDTMF(UInt16 iRefnum,  
TelAppID iAppId, TelSpcPlayDTMFType *iParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iParamP*  
A pointer to a [TelSpcPlayDTMFType](#) structure that specifies the tone to play and its duration.
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSpcPlayDTMFType</a> structure passed to this function in the <code>iParamP</code> parameter
<code>functionId</code>	<code>kTelSpcPlayDTMFMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsSpcServiceAvailable()</a> macro.
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelSpcSendBurstDTMF()</a> , <a href="#">TelSpcStartContinuousDTMF()</a> , <a href="#">TelSpcStopContinuousDTMF()</a>

## TelSpcRejectCall Function

<b>Purpose</b>	Reject an incoming voice telephone call.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelSpcRejectCall (UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	A NULL pointer.
functionId	kTelSpcRejectCallMessage

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcAcceptCall\(\)](#), [TelSpcGetCallerNumber\(\)](#)

## TelSpcRetrieveHeldLine Function

**Purpose** Reconnect the voice line that is currently on hold, making it the active voice line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcRetrieveHeldLine(UInt16 iRefnum,  
TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**  $\rightarrow$  *iRefnum*

The telephony manager library reference number.

$\rightarrow$  *iAppId*

The telephone application attachment identifier for your application.

$\leftrightarrow$  *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	A NULL pointer.
functionId	kTelSpcRetrieveHeldLineMessage

**Comments** Note that there can only be one line active at any given time, and there can only be one line on hold at any given time.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcHoldLine\(\)](#)

## TelSpcSelectLine Function

**Purpose** Select the specified line ID as the newly active voice line.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSpcSelectLine (UInt16 iRefnum,  
 TelAppID iAppId, UInt8 iLineId,  
 UInt16 \*ioTransIdP)

**Parameters**

- *iRefnum*  
 The telephony manager library reference number.
- *iAppId*  
 The telephone application attachment identifier for your application.
- *iLineId*  
 The ID of the voice line that you want to activate. This is the ID returned by a previous call to the [TelSpcAcceptCall\(\)](#) function.
- ↔ *ioTransIdP*  
 Set the value of this parameter to NULL to cause the function to execute synchronously.  
 If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points

to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iLineId</code> parameter.
<code>functionId</code>	<code>kTelSpcSelectLineMessage</code>

**Comments** If a line was active previous to completion of this function, that line is put on hold. Note that there can only be one line active at any given time, and there can only be one line on hold at any given time. Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcConference\(\)](#)

## TelSpcSendBurstDTMF Function

**Purpose** Send a string of dual-tone, multi-frequency sounds to the network system. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcSendBurstDTMF(UInt16 iRefnum, TelAppID iAppId, const Char *iDTMFStringP, UInt16 *ioTransIdP)`

**Parameters**  $\rightarrow$  *iRefnum*  
The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

→ *iDTMFStringP*

A null-terminated string of keytone values. Each byte of the string specifies one of the [Keycode Constants](#).

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the string passed to this function in the <code>iDTMFStringP</code> parameter.
<code>functionId</code>	<code>kTelSpcSendBurstDTMFMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iDTMFStringP` remains in memory until the asynchronous call completes.

---

**Comments**

This function sends a burst string of keytones to the network. Each key tone is played for the default duration defined by the network. Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelSpcPlayDTMF\(\)](#), [TelSpcStartContinuousDTMF\(\)](#), [TelSpcStopContinuousDTMF\(\)](#)

## Telephony Calls

### *TelSpcStartContinuousDTMF*

---

#### **TelSpcStartContinuousDTMF Function**

**Purpose** Send a continuous dual-tone, multi-frequency sound to the network system. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcStartContinuousDTMF(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iKeyCode,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iKeyCode*  
The keycode to send to the network. This must be one of the [Keycode Constants](#).
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>iKeyCode</code> parameter.
<code>functionId</code>	<code>kTelSpcStartContinuousDTMFMessage</code>

<b>Comments</b>	<p>This function sends a key tone to the network system that is played continuously until the <a href="#">TelSpcStopContinuousDTMF()</a> function executes.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsSpcServiceAvailable()</a> macro.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelSpcPlayDTMF()</a> , <a href="#">TelSpcSendBurstDTMF()</a> , <a href="#">TelSpcStopContinuousDTMF()</a>

## TelSpcStopContinuousDTMF Function

<b>Purpose</b>	Stop the continuous playing of a tone that was started by calling the <a href="#">TelSpcStartContinuousDTMF()</a> function.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelSpcStopContinuousDTMF(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:

## Telephony Calls

### *TelSpcStopContinuousDTMF*

---

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	A NULL pointer.
functionId	kTelSpcStopContinuousDTMFMessage

**Comments** This function stops the continuous playing of the tone that was previously initiated by calling the [TelSpcStartContinuousDTMF\(\)](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcPlayDTMF\(\)](#), [TelSpcSendBurstDTMF\(\)](#), [TelSpcStartContinuousDTMF\(\)](#)

# Telephony SMS

---

This chapter describes the telephony SMS service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony SMS Data Structures](#)
- [Telephony SMS Constants](#)
- [Telephony SMS Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony SMS Data Structures

This section describes the data structures used with the SMS service set of the telephony API.

### TelSmsDateTimeType Struct

**Purpose** Several of the other data structures used with the Telephony SMS functions include an `TelSmsDateTimeType` structure to store a date and time value.

**Prototype**

```
typedef _TelSmsDateTimeType
    Boolean    absolute;
    UInt32     dateTime;
} TelSmsDateTimeType
```

## Telephony SMS

### *TelSmsDeleteMessageType*

---

#### Field Descriptions

- |   |                       |   |
|---|-----------------------|---|
| → | <code>absolute</code> | If true, the <code>dateTime</code> value is a Palm™ absolute time value, which is the number of seconds since 1/1/1904. If false, the <code>dateTime</code> value is relative to the current date and time. |
| → | <code>dateTime</code> | The date and time value.  |

If the `absolute` field is true, this is expressed as the number of seconds elapsed since 12:00 A.M. on January 1, 1904. This is the format returned by the [TimGetSeconds\(\)](#) function.

If the `absolute` field is false, this is expressed as the number of seconds elapsed from the current time.

## TelSmsDeleteMessageType Struct

**Purpose** The [TelSmsDeleteMessage\(\)](#) function uses a `TelSmsDeleteMessageType` structure to specify the message to be deleted.

**Prototype**

```
typedef struct _TelSmsDeleteMessageType
    UInt8      messageType;
    UInt16     index;
} TelSmsDeleteMessageType
```

#### Field Descriptions

- |   |                          |   |
|---|--------------------------|---|
| → | <code>messageType</code> | The message type. This is one of the <a href="#">SMS Message Type Constants</a> .   |
| → | <code>index</code>       | The index of the SMS message in the phone's storage that is to be deleted. Note that the message is deleted from the storage area selected by a call to the <a href="#">TelSmsSelectStorage()</a> function. |

Note that the index is zero-based.

## TelSmsDeliveryAdvancedCDMAType Struct

**Purpose** The [TelSmsDeliveryMessageType](#) structure includes a TelSmsDeliveryAdvancedCDMAType structure for CDMA messages.

**Prototype**

```
typedef struct _TelSmsDeliveryAdvancedCDMAType
{
    UInt8                messageType;
    TelSmsDateTimeType  validityPeriod;
    UInt8                priority;
    UInt8                privacy;
    Boolean              alertOnDeliveryRequest;
    Boolean              manualAckRequest;
    UInt8                voiceMessageNumber;
    UInt8                callbackNumberSize;
    Char                 *callbackNumberAddress;
    UInt8                languageIndicator;
} TelSmsDeliveryAdvancedCDMAType
```

### Field Descriptions

messageType	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
validityPeriod	An <a href="#">TelSmsDateTimeType</a> structure that specifies the amount of time for which the message is valid.
priority	The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .
privacy	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
alertOnDeliveryRequest	true if the user is to be alerted upon delivery of this message, and false if not.
manualAckRequest	true if a reply is requested from the user, and false if not.
voiceMessageNumber	

## Telephony SMS

### *TelSmsDeliveryAdvancedGSMTType*

---

<code>callbackNumberSize</code>	<p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>callbackNumberAddress</code> string.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>callbackNumberAddress</code>	<p>A buffer into which the callback number address string is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>languageIndicator</code>	

## TelSmsDeliveryAdvancedGSMTType Struct

**Purpose** The [TelSmsDeliveryMessageType](#) structure includes a `TelSmsDeliveryAdvancedGSMTType` structure for GSM messages.

**Prototype**

```
typedef struct _TelSmsDeliveryAdvancedGSMTType
{
    UInt16      protocolId;
    Boolean     replyPath;
    Char        *serviceCenterNumber;
    UInt8       serviceCenterNumberSize;
} TelSmsDeliveryAdvancedGSMTType
```

### Field Descriptions

←	protocolId	The protocol used for this message. This is one of the <a href="#">SMS Message Transport Protocol Constants</a> .
←	replyPath	If this value is set, then you use the serviceCenterNumber to reply to this message.
	serviceCenterNumber	<p>If this value is not set, you use the default service center provided by your network operator.</p> <p>A buffer into which the service center number string is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a telErrBufferSize error.</p>
	serviceCenterNumberSize	<p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the serviceCenterNumber string.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a telErrBufferSize error.</p>

### TelSmsDeliveryAdvancedTDMAType Struct

**Purpose** The [TelSmsDeliveryMessageType](#) structure includes a TelSmsDeliveryAdvancedTDMAType structure for TDMA messages.

**Prototype** `typedef struct _TelSmsDeliveryAdvancedTDMAType`

## Telephony SMS

### *TelSmsDeliveryAdvancedTDMAType*

---

```
{
    UInt8          messageType;
    TelSmsDateTimeType validityPeriod;
    UInt8          priority;
    UInt8          privacy;
    Boolean         alertOnDeliveryRequest;
    Boolean         manualAckRequest;
    UInt8          voiceMessageNumber;
    UInt8          callbackNumberSize;
    Char            *callbackNumberAddress;
    UInt8          languageIndicator;
} TelSmsDeliveryAdvancedTDMAType
```

#### Field Descriptions

messageType	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
validityPeriod	An <a href="#">TelSmsDateTimeType</a> structure that specifies the amount of time for which the message is valid.
priority	The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .
privacy	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
alertOnDeliveryRequest	true if the user is to be alerted upon delivery of this message, and false if not.
manualAckRequest	true if a reply is requested from the user, and false if not.
voiceMessageNumber	

callbackNumberSize	<p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the callbackNumberAddress string.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a telErrBufferSize error.</p>
callbackNumberAddress	<p>A buffer into which the callback telephone number address string is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a telErrBufferSize error.</p>
languageIndicator	

## TelSmsDeliveryMessageType Struct

**Purpose** The [TelSmsReadMessage\(\)](#) function uses a TelSmsDeliveryMessageType structure to retrieve information about a delivered message.

**Prototype**

```
typedef struct _TelSmsDeliveryMessageType
{
    UInt16          version;
    UInt16          index;
    UInt32          messageIdentifier;
    TelSmsDateTimeType timeStamp;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    UInt8           originatingAddressSize;
}
```

## Telephony SMS

### *TelSmsDeliveryMessageType*

---

```
Char                *originatingAddress;
Boolean             otherToReceive;
Boolean             reportDeliveryIndicator;
UInt8               standardType;

union
{
    TelSmsDeliveryAdvancedGSMTType
                                advancedGSM;
    TelSmsDeliveryAdvancedCDMAType
                                advancedCDMA;
    TelSmsDeliveryAdvancedTDMAType
                                advancedTDMA;
} advancedParams;
UInt8               extensionsCount;
TelSmsExtensionType *extensionsP;
} TelSmsDeliveryMessageType
```

#### Field Descriptions

→	version	The version of the SMS API associated with this message.
	index	Upon return, the SMS index of the message on the phone. This is a 0-based index.
		This value is used for input only when calling the <a href="#">TelSmsReadMessage()</a> function to read one SMS at a time.
←	messageIdentifier	The message identifier.
←	timeStamp	The message time stamp. This is a <a href="#">TelSmsDateTimeType</a> structure.

	dataSize	The size of the data buffer.
		When the structure is used as an input parameter, this is the allocated size of the data buffer.
		Upon return, this is the actual size of the message data. If the buffer is too small to contain the entire message, this field is assigned the entire length of the message, and the function using this structure generates a telErrBufferSize error.
	data	A buffer into which the retrieved data is stored.
		Note that if this buffer is too small to contain the entire retrieved message, the end of the message is truncated and the function using this structure generates a telErrBufferSize error.
←	dataCodingScheme	The coding scheme used for the data. This is one of the <a href="#">SMS Data Coding Scheme Constants</a> .
	originatingAddressSize	The size of the originatingAddress buffer.
		When the structure is used as an input parameter, this is the allocated size of the originatingAddress buffer.
		Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a telErrBufferSize error.

## Telephony SMS

### *TelSmsDeliveryMessageType*

---

	originatingAddress	A buffer into which the originating address string is stored.
		Note that if this buffer is too small to contain the entire string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.
←	otherToReceive	Indicates whether there are more messages waiting to be received from the service center to the mobile device.
←	reportDeliveryIndicator	If true, indicates that the originating user has asked the network to send a delivery report.
←	standardType	Indicates which field of the <code>advancedParams</code> union contains the message information. This is one of the <a href="#">Network Type Constants</a> described in <a href="#">Chapter 70, “Telephony Network.”</a>
		If this value is <code>kTelNwkCDMA</code> , then the <code>advancedParams</code> union contains a <a href="#">TelSmsDeliveryAdvancedCDMAType</a> structure, and similarly for the other values.
	advancedParams	Advanced message information for GSM, CDMA, or TDMA messages. This is one of the following structure types: <a href="#">TelSmsDeliveryAdvancedGSMType</a> <a href="#">TelSmsDeliveryAdvancedCDMAType</a> <a href="#">TelSmsDeliveryAdvancedTDMAType</a>

extensionsCount	On input, this is the number of extension structures allocated for this message. You must allocate at least one structure to specify the multipart information.
	Upon return, this is the number of extensions in the SMS header. If the SMS header contains more extensions than you have allocated, the available extension structures are filled, and this function generates a telErrBufferSize error.
extensionsP	A pointer to an array of <a href="#">TelSmsExtensionType</a> structures that you have allocated for this message. You must allocate this array before using this structure.

## TelSmsExtensionType Struct

**Purpose** The TelSmsExtensionType structure specifies multipart information about a message.

**Prototype**

```
typedef struct _TelSmsExtensionType
    UInt8      extensionTypeId;
    union
    {
        TelSmsMultiPartExtensionType    mp;
        TelSmsNbsExtensionType          nbs;
        TelSmsUserExtensionType          user;
    } extension;
} TelSmsExtensionType
```

## Telephony SMS

### *TelSmsGetAvailableStorageType*

---

#### Field Descriptions

↔	<code>extensionTypeId</code>	Identifies the type of SMS extension structure found in the extension union. This is one of the <a href="#">SMS Extension Type Constants</a> .  If the value of this field is <code>kTelSmsMultipartExtensionTypeId</code> , then the extension union contains a <a href="#">TelSmsMultiPartExtensionType</a> structure.  If the value of this field is <code>kTelSmsNbsExtensionTypeId</code> or <code>kTelSmsNbs2ExtensionTypeId</code> , then the union contains a <a href="#">TelSmsNbsExtensionType</a> structure. The difference between these two is that <code>kTelSmsNbs2ExtensionTypeId</code> indicates that the port value is a long instead of a short.  If this field contains any other value, then the union contains a <a href="#">TelSmsUserExtensionType</a> structure.
←	<code>extension</code>	The extension information, which is one of the following structure types: <a href="#">TelSmsMultiPartExtensionType</a> <a href="#">TelSmsNbsExtensionType</a> <a href="#">TelSmsUserExtensionType</a>

#### TelSmsGetAvailableStorageType Struct

**Purpose** The [TelSmsGetAvailableStorage\(\)](#) function uses a `TelSmsGetAvailableStorageType` structure to retrieve information about the storage available on the phone.

**Prototype**

```
typedef struct _TelSmsGetAvailableStorageType
{
    UInt16    count;
    UInt8     *storagesP;
} TelSmsGetAvailableStorageType
```

### Field Descriptions

↔	count	<p>The size of the storagesP buffer.</p> <p>When the structure is used as an input parameter, this is the allocated number of values in the buffer. Upon return, this is the total number of storage areas in the phone.</p>
←	storagesP	<p>A buffer into which the retrieved storage IDs are stored. Each value stored into the buffer is one of the <a href="#">SMS Storage ID Constants</a>.</p>

## TelSmsGetMessageCountType Struct

**Purpose** The [TelSmsGetMessageCount \(\)](#) function uses a TelSmsGetMessageCountType structure to retrieve information about messages in the currently selected storage.

**Prototype**

```
typedef struct _TelSmsGetMessageCountType
{
    UInt8    messageType;
    UInt16   slots;
    UInt16   count;
} TelSmsGetMessageCountType
```

### Field Descriptions

→	messageType	<p>The type of message for which you want to retrieve the count. This must be one of the <a href="#">SMS Message Type Constants</a>.</p> <p>You must fill this in on input to the <a href="#">TelSmsGetMessageCount ()</a> function.</p>
←	slots	<p>The total number of message slots available in the currently selected storage area (for all message types).</p>
←	count	<p>The number of filled slots for the specified messageType in the currently selected storage area.</p>

## **TelSmsManualAckType Struct**

**Purpose** The [TelSmsSendManualAcknowledge\(\)](#) function uses a TelSmsManualAckType structure to specify the information used to send a message acknowledgment.

**Prototype**

```
typedef struct _TelSmsManualAckType
{
    UInt16      version;
    Char        *destinationAddress;
    UInt32      messageId;
    UInt16      dataSize;
    UInt8       *data;
    UInt8       dataCodingScheme;
    UInt8       responseCode;
} TelSmsManualAckType
```

### **Field Descriptions**

version	The version of the SMS API used for this acknowledgment.
destinationAddress	The destination address. For GSM, the length of this address is 12 bytes. For CDMA, the length is up to 128 bytes.
messageId	Upon return, the ID of the acknowledgment.
dataSize	The size of the data buffer.

When the structure is used as an input parameter, this is the allocated size of the data buffer.

Upon return, this is the actual size of the data. If the buffer is too small to contain all of the data, this field is assigned the entire length of the data, and the function using this structure generates a `telErrBufferSize` error.

data	A buffer into which the retrieved data is stored.
	Note that if this buffer is too small to contain the all of the retrieved data, the data is truncated and the function using this structure generates a telErrBufferSize error.
dataCodingScheme	The coding scheme used for the data. This must be one of the <a href="#">SMS Data Coding Scheme Constants</a> .
responseCode	The response code. The value of this field depends on the network being used.

## TelSmsMultiPartExtensionType Struct

**Purpose** The [TelSmsExtensionType](#) structure uses a TelSmsMultiPartExtensionType structure to describe information about a multipart message.

**Prototype**

```
typedef struct _TelSmsMultiPartExtensionType
    UInt16  bytesSent;
    UInt16  partCurrent;
    UInt16  partCount;
    UInt16  partId;
} TelSmsMultiPartExtensionType
```

### Field Descriptions

↔	bytesSent	On input, set this value to 0.
		Upon return, this is the current count of message bytes that have been sent.
	partCurrent	On input, set this value to 0.
		Upon return, this is the part number of the current message part.

## Telephony SMS

### *TelSmsNbsExtensionType*

---

<code>partCount</code>	On input, set this value to 0.  Upon return, this is the number of message parts required to send the data.
<code>partId</code>	The ID of the current SMS message. This ID is unique and is the same for all parts of the message. This information is required to reassemble a multi-part SMS.  On input, set this value to 0.

## TelSmsNbsExtensionType Struct

**Purpose** The [TelSmsExtensionType](#) structure uses a `TelSmsNbsExtensionType` structure to describe information about a NBS message.

**Prototype**

```
typedef struct _TelSmsNbsExtensionType
    UInt16  destPort;
    UInt16  srcPort;
} TelSmsNbsExtensionType
```

### Field Descriptions

<code>↔</code>	<code>destPort</code>	When the structure is used for input, this is the NBS port number used to encode the data.  Upon return, this is the NBS port number that was used for the data.
	<code>srcPort</code>	This is currently the same as the <code>destPort</code> .

## TelSmsReadMessagesType Struct

**Purpose** The [TelSmsReadMessages\(\)](#) function uses a `TelSmsReadMessagesType` structure to retrieve messages from the currently selected storage area.

**Prototype**    `typedef struct _TelSmsReadMessagesType`  
                   `UInt16                            first;`  
                   `UInt16                            count;`  
                   `TelSmsDeliveryMessageType  *messagesP;`  
                   `} TelSmsReadMessagesType`

### Field Descriptions

→	first	The index of the first message to retrieve. Message indexes are zero-based.
	count	The size of the messagesP buffer.

When the structure is used as an input parameter, this is the allocated number of pointers in the messagesP buffer.

Upon return, this is the number of messages that could be retrieved. If the messagesP buffer is too small to contain all of the messages, this field is assigned the entire count, and the function using this structure generates a `telErrBufferSize` error.

messagesP	An array of pointers to <a href="#">TelSmsDeliveryMessageType</a> structures, each of which is filled in with a retrieved message, if available.
-----------	--

## TelSmsReadReportsType Struct

**Purpose**    The [TelSmsReadReports\(\)](#) function uses a `TelSmsReadReportsType` structure to retrieve reports from the currently selected storage area.

**Prototype**    `typedef struct _TelSmsReadReportsType`  
                   `UInt16                            first;`  
                   `UInt16                            count;`  
                   `TelSmsReportType      *reportsP;`  
                   `} TelSmsReadReportsType`

## Telephony SMS

### *TelSmsReadSubmittedMessagesType*

---

#### Field Descriptions

→	<code>first</code>	The index of the first report to retrieve. Report indexes are zero-based.
	<code>count</code>	The size of the <code>reportsP</code> buffer.

When the structure is used as an input parameter, this is the allocated number of pointers in the `reportsP` buffer.

Upon return, this is the actual number of reports that could be read. If the buffer is too small to contain all of the reports, this field is assigned the entire count, and the function using this structure generates a `telErrBufferSize` error.

<code>reportsP</code>	An array of pointers to <a href="#">TelSmsReportType</a> structures, each of which is filled in with a retrieved message, if available.
-----------------------	---

Note that if this buffer is too small to contain all of the retrieved reports, the function using this structure generates a `telErrBufferSize` error.

#### TelSmsReadSubmittedMessagesType Struct

**Purpose** The [TelSmsReadSubmittedMessages\(\)](#) function uses a `TelSmsReadSubmittedMessagesType` structure to retrieve submitted messages from the currently selected storage area.

**Prototype**

```
typedef struct _TelSmsReadMessagesType
    UInt16          first;
    UInt16          count;
    TelSmsDeliveryMessageType *submittedSP;
} TelSmsReadSubmittedMessagesType
```

### Field Descriptions

→	first	The index of the first message to retrieve. Message indexes are zero-based.
	count	The size of the submittedSP buffer.
		When the structure is used as an input parameter, this is the allocated number of pointers in the submittedSP buffer. Upon return, this is the number of messages that were actually read.
	submittedSP	An array of pointers to <a href="#">TelSmsSubmittedMessageType</a> structures, each of which is filled in with a retrieved message, if available.

## TelSmsReportType Struct

**Purpose** The [TelSmsReadReport\(\)](#) function uses a TelSmsReportType structure to retrieve a report from the report storage area.

**Prototype**

```
typedef struct _TelSmsReportType
{
    UInt16          version;
    UInt16          index;
    UInt8           reportType;
    UInt32          messageId;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    Char            *originatingAddress;
    UInt8           originatingAddressSize;
    UInt8           report;
    TelSmsDateTimeType timeStamp;
} TelSmsReportType
```

### Field Descriptions

→	version	
←	index	The index of the report in the phone storage area.

## Telephony SMS

### *TelSmsReportType*

---

←	reportType	The delivery report type.
←	messageId	The message ID.
	dataSize	The size of the data buffer.
		When the structure is used as an input parameter, this is the allocated size of the data buffer.
		Upon return, this is the actual size of the data. If the buffer is too small to contain all of the data, this field is assigned the entire length of the data, and the function using this structure generates a <code>telErrBufferSize</code> error.
	data	A buffer into which the retrieved data is stored.
		Note that if this buffer is too small to contain the all of the retrieved data, the data is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.
←	dataCodingScheme	The encoding scheme used for the report data. This must be one of the <a href="#">SMS Data Coding Scheme Constants</a> .
	originatingAddress	A buffer into which the originating address is stored.
		Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBuffrSize</code> error.

originatingAddressSize The size of the originatingAddress buffer.  
 ze

Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a telErrBufferSize error.

- ← report The ID of the delivery confirmation report associated with the message.
- ← timeStamp An [TelSmsDateTimeType](#) structure that stores the time at which the message corresponding to the report was received.

## TelSmsSendMessageType Struct

**Prototype**

```
typedef struct _TelSmsSendMessageType
{
    UInt32                messageId;
    TelSmsSubmitMessageType message;
} TelSmsSendMessageType
```

### Field Descriptions

- ← messageId The SMS ID that was assigned by the telephone to the outgoing message.  
  
For a multi-part message, each part has its own message ID.
- message A structure of type [TelSmsSubmitMessageType](#) that contains the message data and parameters.

## TelSmsSubmitAdvancedCDMAType Struct

**Purpose** The [TelSmsSubmitMessageType](#) structure includes a TelSmsSubmitAdvancedCDMAType structure for CDMA messages.

**Prototype**

```
typedef struct _TelSmsSubmitAdvancedCDMAType
{
    Boolean                manualAckRequest;
    UInt8                 messageType;
    TelSmsDateTimeType    deferredDate;
    UInt8                 priority;
    UInt8                 privacy;
    Boolean                alertOnDeliveryRequest;
    Char                  *callbackNumber;
    UInt8                 callbackNumberSize;
} TelSmsSubmitAdvancedCDMAType
```

### Field Descriptions

manualAckRequest	true if a reply is requested from the user, and false if not.
messageType	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
deferredDate	
priority	
privacy	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
alertOnDeliveryRequest	true if the user is to be alerted upon delivery of this message, and false if not.

callbackNumber

A buffer into which the retrieved callback telephone number string is stored.

Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

callbackNumberSize

When the structure is used as an input parameter, this is the allocated size, in bytes, of the `callbackNumber` string.

Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

## **TelSmsSubmitAdvancedGSMTType Struct**

**Purpose** The [TelSmsSubmitMessageType](#) structure includes a `TelSmsSubmitAdvancedGSMTType` structure for GSM messages.

**Prototype**

```
typedef struct _TelSmsSubmitAdvancedGSMTType
{
    UInt16      protocolId;
    Boolean     rejectDuplicatedRequest;
    Boolean     replyPath;
    Char        *serviceCenterNumber;
    UInt8       serviceCenterNumberSize;
} TelSmsSubmitAdvancedGSMTType
```

## Telephony SMS

*TelSmsSubmitAdvancedGSMTType*

---

### Field Descriptions

→	<code>protocolId</code>	<p>Specifies gateway information for routing a message to another transport.</p> <p>Some service centers provide a gateway between SMS and other transports such as mail and FAX. Service centers may reject messages with <code>protocolId</code> values that are reserved or unsupported.</p> <p>The mobile device does not interpret reserved or unsupported values, but does store them as received.</p>
→	<code>rejectDuplicatedRequest</code>	<p>A Boolean value that specifies if the service center should accept a submit message for a submit message that is still held in the service center when that message has the same identifier and destination address as a previously submitted message from the same originating address.</p>
→	<code>replyPath</code>	<p>The path that the service center can use to deliver a reply to the originating message.</p> <p>The reply path is requested by the originating mobile device by setting the <code>replyPath</code> parameter in the original submit message.</p> <p>If the service center supports reply path requests from the mobile device, the service center sets the <code>replyPath</code> parameter in the response.</p>

- `serviceCenterNumber`      A buffer containing the service telephone number string.
- `serviceCenterNumberSize`      The allocated size, in bytes, of the `serviceCenterNumber` string.

## **TelSmsSubmitAdvancedTDMAType Struct**

**Purpose**      The [TelSmsSubmitMessageType](#) structure includes a `TelSmsSubmitAdvancedTDMAType` structure for TDMA messages.

**Prototype**

```
typedef struct _TelSmsSubmitAdvancedTDMAType
{
    Boolean                manualAckRequest;
    UInt8                  messageType;
    TelSmsDateTimeType     deferredDate;
    UInt8                  priority;
    UInt8                  privacy;
    Boolean                alertOnDeliveryRequest;
    Char                   *callbackNumber;
    UInt8                  callbackNumberSize;
} TelSmsSubmitAdvancedTDMAType
```

### **Field Descriptions**

<code>manualAckRequest</code>	true if a reply is requested from the user, and false if not.
<code>messageType</code>	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
<code>deferredDate</code>	
<code>priority</code>	
<code>privacy</code>	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
<code>alertOnDeliveryRequest</code>	true if the user is to be alerted upon delivery of this message, and false if not.

## Telephony SMS

### *TelSmsSubmitMessageType*

---

callbackNumber

A buffer into which the retrieved callback telephone number string is stored.

Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

callbackNumberSize

When the structure is used as an input parameter, this is the allocated size, in bytes, of the `callbackNumber` string.

Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

## TelSmsSubmitMessageType Struct

**Purpose** The [TelSmsReadReports\(\)](#) and [TelSmsSendMessageType](#) structures use a `TelSmsSubmitMessageType` structure to store reports retrieved from the currently selected storage area.

**Prototype**

```
typedef struct _TelSmsSubmitMessageType
{
    UInt16          version;
    Boolean          networkDeliveryRequest;
    Char            *destinationAddress;
    UInt8           destinationAddressSize;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    TelSmsDateTimeType validityPeriod;
    UInt8           standardType;
    union
```

```

{
    TelSmsSubmitAdvancedGSMTType    advancedGSM;
    TelSmsSubmitAdvancedCDMAType    advancedCDMA;
    TelSmsSubmitAdvancedTDMAType    advancedTDMA;
} advancedParams;
UInt8                                extensionsCount;
TelSmsExtensionType                *extensionsP;
} TelSmsSubmitMessageType

```

### Field Descriptions

→	version	The version of the SMS API associated with this message.
→	networkDeliveryRequest	If this value is true, the service center accepts the submit message.
	destinationAddress	A buffer that contains the phone number of the message recipient.
	destinationAddressSize	The size of the destination address string.
	dataSize	The size of the data buffer.
	data	A buffer into which the retrieved message data is stored.
→	dataCodingScheme	The coding scheme used for the data. This is one of the <a href="#">SMS Data Coding Scheme Constants</a> .
→	validityPeriod	An <a href="#">TelSmsDateTimeType</a> structure that specifies the amount of time for which the message is valid.

## Telephony SMS

### *TelSmsSubmittedMessageType*

---

→	<code>standardType</code>	Indicates which field of the <code>advancedParams</code> union contains the message information. This must be one of the <a href="#">Network Type Constants</a> described in <a href="#">Chapter 70, “Telephony Network.”</a>
		If this value is <code>kTelNwkCDMA</code> , then the <code>advancedParams</code> union contains a <a href="#">TelSmsDeliveryAdvancedCDMAType</a> structure, and similarly for the other values.
→	<code>advancedParams</code>	Advanced message information for GSM, CDMA, or TDMA messages. This is a pointer to one of the following structure types: <a href="#">TelSmsSubmitAdvancedCDMAType</a> <a href="#">TelSmsDeliveryAdvancedGSMTType</a> <a href="#">TelSmsDeliveryAdvancedTDMAType</a>
	<code>extensionsCount</code>	The number of extension structures allocated for this message. You must allocate at least one structure to specify the multipart information.
	<code>extensionsP</code>	A pointer to an array of <a href="#">TelSmsExtensionType</a> structures that you have allocated for this message.

## TelSmsSubmittedMessageType Struct

**Purpose** The [TelSmsReadSubmittedMessage\(\)](#) function uses a `TelSmsSubmittedMessageType` structure to retrieve reports from the currently selected storage area.

**Prototype**

```
typedef struct _TelSmsSubmittedMessageType
{
    UInt16                index;
    TelSmsSubmitMessageType message;
} TelSmsSubmittedMessageType
```

### Field Descriptions

→	index	The index of the message on the phone.
←	message	A <a href="#">TelSmsSubmitMessageType</a> structure that represents the message.

## TelSmsUserExtensionType Struct

**Purpose** The [TelSmsExtensionType](#) structure uses a [TelSmsUserExtensionType](#) structure to describe a user-defined extended message header.

**Prototype**

```
typedef struct _TelSmsUserExtensionType
{
    UInt8    *extHeader;
    UInt8    extHeaderSize;
} TelSmsUserExtensionType
```

### Field Descriptions

↔	extHeader	On input, this field must be set to 0.  Upon return, this is a pointer to the user-defined header content.
	extHeaderSize	On input, this field must be set to 0.  Upon return, this is the size of the user-defined header content.

## Telephony SMS Constants

This section describes the constants used with the SMS service set of the telephony API.

## Telephony SMS

### *SMS Extension Type Constants*

---

## SMS Extension Type Constants

The SMS extension type constants describe the type of extension used to represent part of a message.

Constant	Value	Description
kTelSmsMultiPartExtensionTypeId	0x00	A multipart short message.
kTelSmsNbsExtensionTypeId	0x04	An NBS message with short port number value.
kTelSmsNbs2ExtensionTypeId	0x05	An NBS message with long port number value.
(any other value)		A user-defined extension type.

## SMS Message Type Constants

The SMS message type constants describe the delivery type of a message.

Constant	Value	Description
kTelSmsMessageTypeDelivered	0	A delivered message.
kTelSmsMessageTypeReport	1	A report message.
kTelSmsMessageTypeSubmitted	2	A submitted message.
kTelSmsMessageTypeManualAck	3	A manual acknowledgement message.
kTelSmsMessageTypeAllTypes	4	All messages.

## SMS Message Transport Protocol Constants

The SMS message transport protocol constants describe the protocol used to deliver a message.

Constant	Value	Description
<code>ktelSmsDefaultProtocol</code>	0	The default message transport protocol.
<code>kTelSmsFaxProtocol</code>	1	A FAX message.
<code>kTelSmsX400Protocol</code>	2	An X.400 message.
<code>kTelSmsPagingProtocol</code>	3	A paged message.
<code>kTelSmsEmailProtocol</code>	4	An email message.
<code>kTelSmsErmesProtocol</code>	5	An Ermes message.
<code>kTelSmsVoiceProtocol</code>	6	A voice message.

## SMS Storage ID Constants

The SMS storage ID constants describe the storage location of a message.

Constant	Value	Description
<code>kTelSmsStorageSIM</code>	0	Stored in the SIM.
<code>kTelSmsStoragePhone</code>	1	Stored in the phone.
<code>kTelSmsStorageAdaptor</code>	2	Stored in the telephone adaptor.
<code>kTelSmsStorageFirstOem</code>	3	Storage managed by the OEM.

This constant specifies the first OEM storage area. You can specify additional OEM storage areas by incrementing this value. For example, to specify the third OEM storage area, use the following:

`kTelSmsStorageFirstOem+2`

## Telephony SMS

### SMS Data Coding Scheme Constants

---

#### SMS Data Coding Scheme Constants

The SMS data coding scheme constants describe the encoding used for SMS data.

Constant	Value	Description
kTelSms8BitsEncoding	0	8-bit encoding.
kTelSmsBitsASCIIEncoding	1	ANSI X3.4 encoding.
kTelSmsIA5Encoding	2	CCITT T.50 encoding.
kTelSmsIS91Encoding	3	TIA/EIA/IS-91 section 3.7.1 encoding.
kTelSmsUCS2Encoding	4	UCS2 encoding; used with GSM only.
kTelSmsDefaultGSMEncoding	5	Default encoding for GSM only.

#### SMS Message Urgency Constants

The SMS message urgency constants describe the priority level of a message in a [TelSmsDeliveryAdvancedCDMAType](#) or [TelSmsDeliveryAdvancedTDMAType](#) structure.

Constant	Value	Description
kTelSmsUrgencyNormal	0	Normal urgency.
kTelSmsUrgencyUrgent	1	An urgent message.
kTelSmsUrgencyEmergency	2	An emergency message.

#### SMS Message Privacy Constants

The SMS message privacy constants describe the privacy type of a message in a CDMA or TDMA advanced parameters.

Constant	Value	Description
kTelSmsPrivacyNotRestricted	0	Privacy level 0.
kTelSmsPrivacyRestricted	1	Privacy level 1.
kTelSmsPrivacyConfidential	2	Privacy level 2.
kTelSmsPrivacySecret	3	Privacy level 3.

---

## Telephony SMS Functions

This section describes the functions used with the SMS service set of the telephony API.

### TelSmsDeleteMessage Function

<b>Purpose</b>	Delete an SMS report, delivered message, or submitted message.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelSmsDeleteMessage(UInt16 iRefnum,                           TelAppID iAppId,                           TelSmsDeleteMessageType *ioParamP,                           UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i>  A pointer to a <a href="#">TelSmsDeleteMessageType</a> structure that specifies the index and type of the message to delete.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.   If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>

## Telephony SMS

### *TelSmsGetAvailableStorage*

---

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsDeleteMessageType</a> structure passed to this function in the <code>iDelInfoP</code> parameter.
<code>functionId</code>	<code>kTelSmsDeleteMessageMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** If the deleted message has been delivered, the deletion is performed in the current storage, which you can set with the [TelSmsSelectStorage\(\)](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

## TelSmsGetAvailableStorage Function

**Purpose** Retrieve the list of all available storage on the phone.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsGetAvailableStorage(UInt16 iRefnum,
                              TelAppID iAppId,
                              TelSmsGetAvailableStorageType *ioParamP,
                              UInt16 *ioTransIdP)
```

**Parameters**  $\rightarrow$  `iRefnum`  
The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelSmsGetAvailableStorageType](#) structure that is filled in with information about the storage areas available on the phone.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsGetAvailableStorageType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelSmsGetAvailableStorageMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments**

The count of storage areas available on the phone is stored into the `count` field of the [TelSmsGetAvailableStorageType](#) structure referenced by `ioParamP`, and the storage ID of each available room is stored into the buffer referenced by the `storagesP` field. If the `storagesP` buffer is too small to contain all of the storage IDs, the

buffer is truncated and this function returns the `telErrBufferSize` error. The `count` field of the structure is always updated to contain the total number of available storage areas on the phone.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

### TelSmsGetDataMaxSize Function

**Purpose** Returns the maximum length, in bytes, of a message on the current network.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsGetDataMaxSize(UInt16 iRefnum,
    TelAppID iAppId, UInt16 *oSizeP,
    UInt16 *ioTransIdP)
```

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

← *oSizeP*

A pointer to an unsigned integer value that is updated with the maximum length of an SMS message on the current network.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr> <tr> <td>transId</td><td>The transaction ID of the operation.</td></tr> <tr> <td>paramP</td><td>Points to the unsigned integer value passed to this function in the oSizeP parameter.</td></tr> <tr> <td>functionId</td><td>kTelGetDataMaxSizeMessage</td></tr> </table> <hr/> <p><b>WARNING!</b> When using this function asynchronously, you must ensure that the value referenced by oSizeP remains in memory until the asynchronous call completes.</p> <hr/>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to the unsigned integer value passed to this function in the oSizeP parameter.	functionId	kTelGetDataMaxSizeMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to the unsigned integer value passed to this function in the oSizeP parameter.								
functionId	kTelGetDataMaxSizeMessage								
<b>Comments</b>	<p>You can use this function to determine the maximum size you need to allocate to read a message.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsSmsServiceAvailable()</a> macro.</p>								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelSmsReadMessage()</a> , <a href="#">TelSmsReadMessages()</a>								

## TelSmsGetMessageCount Function

<b>Purpose</b>	Retrieve the total number of message slots, and the number of filled slots for the specified message type.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelSmsGetMessageCount (UInt16 iRefnum,     TelAppID iAppId,     TelSmsGetMessageCountType *ioParamP,     UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p>

↔ *ioParamP*

A pointer to a [TelSmsGetMessageCountType](#) structure that specifies the message type and is filled in with the count information.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsGetMessageCountType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelSmsGetMessageCountMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The currently selected storage area pertains only to delivered messages; other message types are stored on the phone, but not in a specific storage area. If you specify delivered messages, this function retrieves information about the messages in the currently selected SMS storage area on the phone. If you specify a different message type, this function retrieves information about the messages in the phone.

You specify the message type by assigning one of the [SMS Message Type Constants](#) to the `messageType` field of the

TelSmsGetMessageCountType structure before calling this function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

## TelSmsGetSelectedStorage Function

**Purpose** Retrieve the ID of the currently selected storage area on the phone.

**Declared In** TelephonyMgr.h

**Prototype**

```
Err TelSmsGetSelectedStorage(UInt16 iRefnum,
                             TelAppID iAppId, UInt8 *oStorageIdP,
                             UInt16 *ioTransIdP)
```

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

← *oStorageIdP*

A pointer to an unsigned byte value that is assigned the ID of the currently selected storage area on the phone. The assigned ID value is one of the [SMS Storage ID Constants](#).

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the oStorageIdP parameter.
functionId	kTelGetSelectedStorageMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oStorageIdP remains in memory until the asynchronous call completes.

---

**Comments** The currently selected storage area pertains only to delivered messages; other message types are stored on the phone, but not in a specific storage area.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

## TelSmsGetUniquePartId Function

**Purpose** Return a unique part identifier to assign to the partId field of a submit message.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSmsGetUniquePartId(UInt16 iRefnum,  
TelAppID iAppId, UInt16 \*oUniqueIdP,  
UInt16 \*ioTransIdP)

**Parameters** → *iRefnum*  
The telephony manager library reference number.  
→ *iAppId*  
The telephone application attachment identifier for your application.

← *oUniqueIdP*

A pointer to a unsigned integer value. Upon return, this is the unique part ID value.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oUniqueIdP</code> parameter.
<code>functionId</code>	<code>kTelGetUniquePartIdMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oUniquePartIdP` remains in memory until the asynchronous call completes.

---

**Comments**

This function corresponds to the `kTelUrqSmsGetUniquePartIdMessage` value.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelSmsSendMessage\(\)](#)

## **TelSmsReadMessage Function**

- Purpose** Retrieve a delivered message from the currently selected storage area.
- Declared In** `TelephonyMgr.h`
- Prototype**

```
Err TelSmsReadMessage(UInt16 iRefnum,
                        TelAppID iAppId,
                        TelSmsDeliveryMessageType *ioMessageP,
                        UInt16 *ioTransIdP)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ↔ *ioMessageP*  
A pointer to a [TelSmsDeliveryMessageType](#) structure that is filled in with the message.  
  
On input, the `index` field of this structure contains the index of the message that you want retrieved. Message indexes are zero-based.  
  
On input, the `extensionsCount` field specifies the number of extensions allocated in the `extensionsP` array. You must allocate at least one multi-part extension, even for a single-part message.  
  
On input, the `dataSize` field specifies the allocated size of the data buffer, and the `originatingAddressSize` field specifies the allocated size of the `originatingAddress` string. Upon return, each size field specifies the complete size of the data that was stored into the buffer, even if the data had to be truncated to fit.
  - ↔ *ioTransIdP*  
Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the <a href="#">TelSmsDeliveryMessageType</a> structure passed to this function in the <code>ioMessageP</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelSmsReadMessageMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the <a href="#">TelSmsDeliveryMessageType</a> structure passed to this function in the <code>ioMessageP</code> parameter.	<code>functionId</code>	<code>kTelSmsReadMessageMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the <a href="#">TelSmsDeliveryMessageType</a> structure passed to this function in the <code>ioMessageP</code> parameter.								
<code>functionId</code>	<code>kTelSmsReadMessageMessage</code>								
<p><b>WARNING!</b> When using this function asynchronously, you must ensure that the structure referenced by <code>ioMessageP</code> remains in memory until the asynchronous call completes.</p>									

**Comments** The message data is stored into the `data` field of the [TelSmsDeliveryMessageType](#) structure referenced by `ioMessageP`. If the complete message data is too large to fit into the allocated size of the `data` field, the message data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the message data.

The originating address string is stored into the `originatingData` field of the [TelSmsDeliveryMessageType](#) structure referenced by `ioMessageP`. If the complete string is too large to fit into the allocated size of the `originatingData` field, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `originatingAddressSize` field of the structure is always updated to contain the actual size of the string.

Before calling this function, you need to allocate a number of fields and structures in and related to the `TelSmsDeliveryMessage` structure:

- Allocate each address field with a size of at least `kTelMaxPhoneNumberLen + 1`.  
For example, for a GSM message, you must allocate the `originatingAddress` and `serviceCenterNumber` fields in the [TelSmsDeliveryAdvancedGSMTType](#) structure in the `TelSmsDeliveryMessage` structure.
- Allocate the message field data to have the maximum size of a message on the current network. You can determine this value by calling the [TelSmsGetDataMaxSize\(\)](#) function.
- Allocate at least one [TelSmsExtensionType](#) structure in the `TelSmsDeliveryMessage` structure. You must have at least one extension structure, even if your message has only a single part. If you do not allocate enough extensions for the message, [TelSmsReadMessage\(\)](#) returns an error. Palm recommends allocating between 3 and 5 extensions for a message.
- You should not allocate a pointer for user extension data. If you receive user extension data, the user extension pointer will reference a block in the message data. Do not deallocate the user extension data when you release the structure.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

## TelSmsReadMessages Function

**Purpose** Retrieve a range of delivered messages from the currently selected storage area.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadMessages(UInt16 iRefnum,
                        TelAppID iAppId,
                        TelSmsReadMessagesType *ioParamP,
                        UInt16 *ioTransIdP)
```

**Parameters**  $\rightarrow$  *iRefnum*  
The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelSmsReadMessagesType](#) structure.

On input, the `first` field of this structure specifies the index of the first message to retrieve. Message indexes are zero-based.

On input the `count` field of this structure specifies the allocated size of the `messagesP` buffer. Upon return, the `count` field specifies the actual number of messages that were available, even if that many could not fit into the buffer.

The `messagesP` buffer must contain pointers to [TelSmsDeliveryMessageType](#) structures that have been allocated. Each of these structures must be initialized as described for the [TelSmsReadMessage\(\)](#) function.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous  
Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous  
Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsReadMessagesType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelSmsReadMessagesMessage</code>

## Telephony SMS

### *TelSmsReadReport*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structures referenced by it remain in memory until the asynchronous call completes.

---

**Comments** If the message data or originating address string data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the data is truncated into the buffer, and this function returns the `telErrBufferSize` error.

For more information about using this function and allocating structures for its use, see the Comments description for the [TelSmsReadMessage\(\)](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#)

## TelSmsReadReport Function

**Purpose** Read a report from the currently selected storage area.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadReport (UInt16 iRefnum,
    TelAppID iAppId, TelSmsReportType *ioReportP,
    UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.

↔ *ioReportP*

A pointer to a [TelSmsReportType](#) structure.

On input the `index` field of this structure contains the index of the message that you want retrieved. Message indexes are zero-based.

On input, the `dataSize` field specifies the allocated size of the data buffer, and the `originatingAddressSize` field specifies the allocated size of the `originatingAddress` string. Upon return, each size field specifies the complete size of the data that was stored into the buffer, even the data had to be truncated to fit.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsReportType</a> structure passed to this function in the <code>ioReportP</code> parameter.
<code>functionId</code>	<code>kTelSmsReadReportMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments**

The report data is stored into the `data` field of the [TelSmsReportType](#) structure referenced by `ioReportP`. If the

## Telephony SMS

### *TelSmsReadReports*

---

complete message data is too large to fit into the allocated size of the data field, the report data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the report data.

The originating address string is stored into the `originatingData` field of the [TelSmsReportType](#) structure referenced by `ioReportP`. If the complete string is too large to fit into the allocated size of the `originatingData` field, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `originatingAddressSize` field of the structure is always updated to contain the actual size of the string.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#), [TelSmsSendMessage\(\)](#)

## TelSmsReadReports Function

**Purpose** Retrieve a range of reports from the currently selected storage.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadReports(UInt16 iRefnum,
    TelAppID iAppId,
    TelSmsReadReportsType *ioParamP,
    UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelSmsReadReportsType](#) structure.

On input, the `first` field of this structure specifies the index of the first report to retrieve. Report indexes are zero-based.

On input the `count` field of this structure specifies the allocated size of the `reportsP` buffer. Upon return, the `count` field specifies the actual number of reports that were available, even if that many could not fit into the buffer.

The `reportsP` buffer must contain pointers to [TelSmsReportType](#) structures that have been allocated. Each of these structures must be initialized as described for the [TelSmsReadReport\(\)](#) function.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelSmsReadReportsType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelSmsReadReportsMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structured referenced by it remain in memory until the asynchronous call completes.

---

## Telephony SMS

### *TelSmsReadSubmittedMessage*

---

- Comments** If the report data or originating address string data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the data is truncated into the buffer, and this function returns the `telErrBufferSize` error. For more information, see the Comments description for the [TelSmsReadReport\(\)](#) function.
- Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [TelSmsSelectStorage\(\)](#), [TelSmsSendMessage\(\)](#)

## TelSmsReadSubmittedMessage Function

- Purpose** Read a previously submitted message that was kept on the phone after being sent.
- Declared In** `TelephonyMgr.h`
- Prototype**
- ```
Err TelSmsReadSubmittedMessage (UInt16 iRefnum,
                                TelAppID iAppId,
                                TelSmsSubmittedMessageType *ioMessageP,
                                UInt16 *ioTransIdP)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ↔ *ioMessageP*  
A pointer to a [TelSmsSubmitMessageType](#) structure that is filled in with the message.  
  
On input, the `index` field contains the index of the message that you want retrieved. Message indexes are zero-based.  
  
Upon return, the message field structure is filled in with the message information. You must initialize the buffer size fields of this structure prior to calling this function, including the `dataSize`, `callbackNumberSize`, `serviceCenterNumberSize`, and

destinationAddressSize fields. Each of these fields is initialized with the allocated size of its corresponding buffer.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                                  |
| <code>transId</code>    | The transaction ID of the operation.                                                                                              |
| <code>paramP</code>     | Points to the <a href="#">TelSmsSubmitMessageType</a> structure passed to this function in the <code>ioMessageP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsSubmittedMessageMessage</code>                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments**

The message data is stored into the data field of the [TelSmsSubmitMessageType](#) structure referenced by `ioMessageP`. If the complete message data is too large to fit into the allocated size of the data field, the end of the message data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the message data.

The same strategy applies to the `callbackNumber` buffer and `callbackNumberSize` fields, the `destinationAddress` buffer and `destinationAddressSize` fields, and the `serviceCenterNumber` buffer and

## Telephony SMS

### *TelSmsReadSubmittedMessages*

---

serviceCenterNumberSize fields. If the size of the data for any of the buffer fields exceeds the allocated length of the buffer, the end of the data is truncated and this function returns the `telErrBufferSize` error. Each of the size fields is always updated to contain the complete size of the data intended for the buffer.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#), [TelSmsSendMessage\(\)](#)

## TelSmsReadSubmittedMessages Function

**Purpose** Retrieve a range of submitted messages from the currently selected storage area.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSmsReadSubmittedMessages(UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsReadSubmittedMessagesType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelSmsReadMessagesType](#) structure.

On input, the `first` field of this structure specifies the index of the first message to retrieve. Message indexes are zero-based.

On input, the `count` field of this structure specifies the allocated size of the `submittedsP` buffer. Upon return, the `count` field specifies the actual number of messages that were available, even if that many could not fit into the buffer.

The `submittedsP` buffer must contain pointers to [TelSmsSubmittedMessageType](#) structures that have been

allocated. Each of these structures must be initialized as described for the [TelSmsReadSubmittedMessage\(\)](#) function.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                                        |
| <code>transId</code>    | The transaction ID of the operation.                                                                                                    |
| <code>paramP</code>     | Points to the <a href="#">TelSmsReadSubmittedMessagesType</a> structure passed to this function in the <code>ioParamP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsReadSubmittedMessagesMessage</code>                                                                                        |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structured referenced by it remain in memory until the asynchronous call completes.

---

**Comments**

If the message data or any of the other variable-length data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the end of the data is truncated, and this function returns the `telErrBufferSize` error. For more information, see the Comments description for the [TelSmsReadSubmittedMessage\(\)](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

## Telephony SMS

### *TelSmsSelectStorage*

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage\(\)](#), [TelSmsSendMessage\(\)](#)

## TelSmsSelectStorage Function

**Purpose** Select a storage area on the phone as the current storage area.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSmsSelectStorage(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iStorageId,  
UInt16 *ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iStorageId*  
The ID of the storage area. This must be one of the [SMS Storage ID Constants](#).
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

|                      |                                                                                                                                     |                                                                                                         |

## Telephony SMS

### *TelSmsSendMessage*

---

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                          |
| <code>transId</code>    | The transaction ID of the operation.                                                                                      |
| <code>paramP</code>     | Points to the <a href="#">TelSmsManualAckType</a> structure passed to this function in the <code>ioAckP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsSendManualAcknowledgeMessage</code>                                                                          |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments**

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

## TelSmsSendMessage Function

**Purpose**

Send an SMS message.

**Declared In**

`TelephonyMgr.h`

**Prototype**

```
Err TelSmsSendMessage(UInt16 iRefnum,
    TelAppID iAppId,
    TelSmsSendMessageType *ioMessageP,
    UInt16 *ioTransIdP)
```

**Parameters**

→ *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioMessageP*

A pointer to a structure of type [TelSmsSendMessageType](#).

On input, the message field of this structure contains a [TelSmsSubmitMessageType](#) with the message to send. You must also allocate and zero at least one [TelSmsExtensionType](#) structure for the multi-part information.

On output, the messageId field of this structure is filled in with the ID that was assigned to the sent message.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelSmsSendMessageType](#) structure passed to this function in the `ioMessageP` parameter.

`functionId`      `kTelSmsSendMessageMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioMessageP` remains in memory until the asynchronous call completes.

---

**Comments**

You need to make multiple calls to the [TelSmsSendMessage\(\)](#) function to send your message:

### *TelSmsSendMessage*

---

- The first call to `TelSmsSendMessage` does not actually send the message. It computes the number of parts and fills in the multi-part extension structures in the `TelSmsSendMessageType` structure. Note that you must allocate at least one extension structure, even for single-part messages.
- Subsequent calls to `TelSmsSendMessage` actually send the data.
- To send an entire message, you need to call `TelSmsSendMessage` in a loop. Terminate the loop when an error occurs, or when the `byteSend` field of the first [TelSmsExtensionType](#) structure has the same value as the `dataSize` field of the [TelSmsSendMessageType](#) structure that represents the message. For example:

---

```
while (!TelSmsSendMessage(...) &&
      msg.extensionP[0].extension.mp.byteSend != dataSize);
```

---

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable\(\)](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

# Telephony Phone Book

---

This chapter describes the phone book service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Phone Book Data Structures](#)
- [Telephony Phone Book Constants](#)
- [Telephony Phone Book Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Phone Book Data Structures

This chapter describes the data structures used with the phone book service set of the telephony API.

### TelPhbEntryType Struct

**Purpose** The TelPhbEntryType structure describes a single entry in a phone book.

**Prototype**

```
typedef struct _TelPhbEntryType
{
    UInt16    phoneIndex;
    Char      *fullName;
    UInt8     fullNameSize;
```

## Telephony Phone Book

### *TelPhbEntryType*

---

```
    Char        *dialNumber;  
    UInt8       dialNumberSize;  
} TelPhbEntryType
```

#### Field Descriptions

|   |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| → | phoneIndex   | <p>The index of the entry in the phone's phone book. This index is always zero-based.</p> <p>The telephony manager is responsible for converting this index into the physical index in the phone, if required.</p>                                                                                                                                                                                                                                                                                                                   |
| ← | fullName     | <p>A buffer into which the retrieved full name of the entry is stored.</p> <p>This string is stored using the local character set of the Palm™ handheld device. The telephony manager is responsible for converting the character set, if required.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the string is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.</p>                                                                          |
|   | fullNameSize | <p>The size of the <code>fullName</code> string.</p> <p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>fullName</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the <code>fullName</code> buffer is too small to contain all of the retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p> |

←      `dialNumber`      A buffer into which the retrieved telephone number of the entry is stored.

Note that if this buffer is too small to contain the entire retrieved string, the string is truncated, and the function using this structure generates a `telErrBufferSize` error.

`dialNumberSize`      The size of the `dialNumber` string.

When the structure is used as an input parameter, this is the allocated size, in bytes, of the `dialNumber` buffer.

Upon return, this is the actual size of the string, including the null terminator character. If the `dialNumber` buffer is too small to contain all of the retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

## **TelPhbGetAvailablePhonebooksType Struct**

**Purpose**      The [`TelPhbGetAvailablePhonebooks\(\)`](#) functions uses the `TelPhbGetAvailablePhonebooksType` structure to return a list of the phone books available on the phone.

**Prototype**

```
typedef struct _TelPhbGetAvailablePhonebooksType
{
    UInt16    count;
    UInt8     *phonebooksP;
} TelPhbGetAvailablePhonebooksType
```

## Telephony Phone Book

### *TelPhbGetEntriesType*

---

#### Field Descriptions

|   |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ↔ | count       | The number of entries in the array referenced by phonebooksP.<br><br>When the structure is used as an input parameter, this is the allocated size, in bytes, of the phonebooksP buffer. Upon return, this is the actual size of the retrieved data.<br><br>Upon return, this is the actual number of phone book IDs that could be retrieved. If the phonebooksP buffer is too small to contain all of the IDs, this field is assigned the actual count, and the function using this structure generates a telErrBufferSize error. |
| ← | phonebooksP | An array of retrieved phone book IDs. Each ID is one of the <a href="#">Phone Book Type Constants</a> .                                                                                                                                                                                                                                                                                                                                                                                                                           |

#### TelPhbGetEntriesType Struct

**Purpose** The [TelPhbGetEntries\(\)](#) function uses the TelPhbGetEntriesType structure to return a list of phone entries.

**Prototype**

```
typedef struct _TelPhbGetEntriesType
{
    UInt16          first;
    UInt16          count;
    TelPhbEntryType *entriesP;
} TelPhbGetEntriesType
```

### Field Descriptions

|   |          |                                                                                                      |
|---|----------|------------------------------------------------------------------------------------------------------|
| → | first    | The index of the first entry in the array referenced by <code>entriesP</code> .                      |
|   | count    | When the structure is used as an input parameter, this is number of entries that you want retrieved. |
|   |          | Upon return, this is the actual number of entries that were retrieved.                               |
| ← | entriesP | An array of pointers to retrieved <a href="#">TelPhbEntryType</a> structures.                        |

## TelPhbGetEntryCountType Struct

**Purpose** The [TelPhbGetEntryCount\(\)](#) function uses the `TelPhbGetEntryCountType` structure to return information about the entries in the currently selected phone book.

**Prototype**

```
typedef struct _TelPhbGetEntryCountType
{
    UInt16      slots;
    UInt16      count;
} TelPhbGetEntryCountType
```

### Field Descriptions

|   |       |                                                              |
|---|-------|--------------------------------------------------------------|
| ← | slots | The total number of entry slots available in the phone book. |
| c | count | The number of filled slots in the phone book.                |

## TelPhbGetEntryMaxSizesType Struct

**Purpose** The [TelPhbGetEntryMaxSizes\(\)](#) function uses the `TelPhbGetEntryMaxSizesType` structure to return size information about the entries in the currently selected phone book.

**Prototype**

```
typedef struct _TelPhbGetEntryMaxSizeType
{
```

## Telephony Phone Book

### Telephony Phone Book Constants

---

```
    UInt8      fullNameMaxSize;
    UInt8      dialNumberMaxSize;
} TelPhbGetEntryMaxSizesType
```

#### Field Descriptions

- ← `fullNameMaxSize` The largest size of any `fullName` field in the phone book.
- ← `dialNumberMaxSize` The largest size of any `dialNumber` field in the phone book.

## Telephony Phone Book Constants

This section describes the constants used with the phone book service set of the telephony API.

### Phone Book Type Constants

The phone book type constants specify the type of phone book that is currently selected.

| Constant                                 | Value | Description                                                            |
|------------------------------------------|-------|------------------------------------------------------------------------|
| <code>kTelPhbFixedPhonebook</code>       | 0     | The phone book stored on the phone.                                    |
| <code>kTelPhbSimPhonebook</code>         | 1     | The phone book stored on the SIM card.                                 |
| <code>kTelPhbPhonePhonebook</code>       | 2     | The phone book stored on the phone.                                    |
| <code>kTelPhbLastDialedPhonebook</code>  | 3     | The phone book from which a telephone number was most recently dialed. |
| <code>kTelPhbSimAndPhonePhonebook</code> | 4     | The combined phone and SIM card phone books.                           |

| Constant                 | Value | Description                                     |
|--------------------------|-------|-------------------------------------------------|
| kTelPhbAdaptorPhonebook  | 5     | The phone book stored on the telephone adaptor. |
| kTelPhbFirstOemPhonebook | 6     | The ID of the first OEM phone book.             |

You can specify additional OEM phone books by incrementing this value; for example, the second OEM phone book is specified as:

kTelPhbFirstOemPhonebook  
+1

---

## Telephony Phone Book Functions

This section describes the functions used with the phone book service set of the telephony API.

### TelPhbAddEntry Function

|                    |                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Add or replace an entry in the currently selected phone book.                                                                                                                                                                                                                                              |
| <b>Declared In</b> | TelephonyMgr.h                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | Err TelPhbAddEntry(UInt16 iRefnum,<br>TelAppID iAppId, TelPhbEntryType *iEntryP,<br>UInt16 *ioTransIdP)                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>iRefnum</i><br/>The telephony manager library reference number.</p> <p>→ <i>iAppId</i><br/>The telephone application attachment identifier for your application.</p> <p>→ <i>iEntryP</i><br/>A pointer to a <a href="#">TelPhbEntryType</a> structure that contains the new entry information.</p> |

## Telephony Phone Book

### *TelPhbAddEntry*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`          Points to the [TelPhbEntryType](#) structure passed to this function in the `iEntryP` parameter.

`functionId`      `kTelPhbAddEntryMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The `phoneIndex` field of the [TelPhbEntryType](#) structure referenced by `iEntryP` specifies the index at which to write the entry.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelPhbDeleteEntry\(\)](#), [TelPhbSelectPhonebook\(\)](#)

## TelPhbDeleteEntry Function

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                         |                                                                  |                      |                                      |                     |                                                                                                         |                         |                                        |

| <code>returnCode</code>    | <code>errNone</code> upon success or an error code upon failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                         |                                                                  |                      |                                      |                     |                                                                                                         |                         |                                        |
| <code>transId</code>       | The transaction ID of the operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                         |                                                                  |                      |                                      |                     |                                                                                                         |                         |                                        |
| <code>paramP</code>        | Points to the unsigned integer value passed to this function in the <code>iEntryIndex</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                         |                                                                  |                      |                                      |                     |                                                                                                         |                         |                                        |
| <code>functionId</code>    | <code>kTelPhbDeleteEntryMessage</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                         |                                                                  |                      |                                      |                     |                                                                                                         |                         |                                        |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

- Comments** Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [TelPhbAddEntry\(\)](#), [TelPhbSelectPhonebook\(\)](#)

## TelPhbGetAvailablePhonebooks Function

- Purpose** Retrieve the list of all phone books available on the phone.
- Declared In** `TelephonyMgr.h`
- Prototype**

```
Err TelPhbGetAvailablePhonebooks(UInt16 iRefnum,
    TelAppID iAppId,
    TelPhbGetAvailablePhonebooksType *ioParamP,
    UInt16 *ioTransIdP)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ↔ *ioParamP*  
A pointer to a [TelPhbGetAvailablePhonebooksType](#) structure that lists the available phone books.  
  
On input, the count field of this structure specifies the allocated size of the phonebookP buffer. Upon return, the count field specifies the actual number of entries retrieved, even if they were truncated to fit into the buffer.
  - ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points

to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                                        |
| <code>transId</code>    | The transaction ID of the operation.                                                                                                    |
| <code>paramP</code>     | Points to the <a href="#">TelPhbGetAvailablePhonebooksType</a> structure passed to this function in the <code>iEntryP</code> parameter. |
| <code>functionId</code> | <code>kTelPhbGetAvailablePhonebooksMessage</code>                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments**

The phone book IDs are stored into the `phonebookP` field of the [TelPhbGetAvailablePhonebooksType](#) structure referenced by `ioParamP`. If the `phonebookP` buffer is too small to contain all of the IDs, the information is truncated and this function returns the `telErrBufferSize` error. The `count` field of the structure is always updated to contain the actual number of entries that were retrieved.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

## TelPhbGetEntries Function

- Purpose** Retrieve a range of entries from the currently selected phone book.
- Declared In** `TelephonyMgr.h`
- Prototype**

```
Err TelPhbGetEntries (UInt16 iRefnum,
                      TelAppID iAppId,
                      TelPhbGetEntriesType *ioParamP,
                      UInt16 *ioTransIdP)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ↔ *ioParamP*  
A pointer to a [TelPhbGetEntriesType](#) structure that is updated with the phone book entry information. The first entry retrieved is specified in the `first` field of this structure, which is zero-based; the number of entries retrieved is specified by the `count` field. Thus, the last entry retrieved is specified by:  

```
ioParamP->first +  
    ioParamP->count - 1
```

Upon return, the `count` field of the structure is the number of entries that were actually retrieved.

The `entriesP` field of this structure is a buffer that you allocate to contain the required number of pointers. Each pointer references a [TelPhbEntryType](#) structure that you must also preallocate.

On input, the `fullNameSize` and `dialNumberSize` fields of this structure specify the allocated sizes of the `fullName` and `dialNumber` buffers. Upon return, the `fullNameSize` and `dialNumberSize` fields specify the actual sizes of the buffers, even if a string was truncated to fit into the buffer.
  - ↔ *ioTransIdP*  
Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points

to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure                                                                |
| <code>transId</code>    | The transaction ID of the operation.                                                                                           |
| <code>paramP</code>     | Points to the <a href="#">TelPhbGetEntriesType</a> structure passed to this function in the <code>ioEntriesP</code> parameter. |
| <code>functionId</code> | <code>kTelPhbGetEntriesMessage</code>                                                                                          |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and any structures that it references remain in memory until the asynchronous call completes.

---

**Comments**

The phone book information is stored into the [TelPhbEntryType](#) structures that you preallocate and refer to in the `entriesP` field of the [TelPhbGetEntriesType](#) referenced by the `ioParamP` parameter.

If any buffer in any of the [TelPhbEntryType](#) structures is too small, the string intended for that buffer is truncated, and this function returns the `telErrBufferSize` error. In any case, the `fullNameSize` and `dialNumberSize` fields of each [TelPhbEntryType](#) structure contain the actual size of their respective strings.

If any entries in the specified range are empty, the entry is not retrieved, and the `count` value in the structure is updated.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetEntry\(\)](#), [TelPhbSelectPhonebook\(\)](#)

## TelPhbGetEntry Function

**Purpose** Retrieve one entry from the currently selected phone book.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelPhbGetEntry(UInt16 iRefnum,
                    TelAppID iAppId, TelPhbEntryType *ioEntryP,
                    UInt16 *ioTransIdP)
```

**Parameters**  $\rightarrow$  *iRefnum*

The telephony manager library reference number.

$\rightarrow$  *iAppId*

The telephone application attachment identifier for your application.

$\leftrightarrow$  *ioEntryP*

A pointer to a [TelPhbEntryType](#) structure that is updated with the phone book entry information.

On input, the `fullNameSize` and `dialNumberSize` fields of this structure specify the allocated sizes of the `fullName` and `dialNumber` buffers. Upon return, the `fullNameSize` and `dialNumberSize` fields specify the actual sizes of the buffers, even if a string was truncated to fit into the buffer.

$\leftrightarrow$  *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|            |                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------|
| returnCode | errNone upon success or an error code upon failure.                                                        |
| transId    | The transaction ID of the operation.                                                                       |
| paramP     | Points to the <a href="#">TelPhbEntryType</a> structure passed to this function in the ioEntryP parameter. |
| functionId | kTelPhbGetEntryMessage                                                                                     |

**Comments**     The phone book information is stored into the [TelPhbEntryType](#) that you preallocate. If either buffer in the structure is too small, the string intended for that buffer is truncated, and this function returns the telErrBufferSize error. In any case, the fullNameSize and dialNumberSize fields of the structure contain the actual size of their respective strings.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

**Compatibility**     Implemented only if [4.0 New Feature Set](#) is present.

**See Also**     [TelPhbGetEntries\(\)](#), [TelPhbSelectPhonebook\(\)](#)

## TelPhbGetEntryCount Function

**Purpose**     Retrieve the total number of entries, and the number of filled entries in the currently selected phone book.

**Declared In**     TelephonyMgr.h

**Prototype**

```
Err TelPhbGetEntryCount (UInt16 iRefnum,
                        TelAppID iAppId,
                        TelPhbGetEntryCountType *oParamP,
                        UInt16 *ioTransIdP)
```

**Parameters**      $\rightarrow$  *iRefnum*  
                       The telephony manager library reference number.

$\rightarrow$  *iAppId*  
                       The telephone application attachment identifier for your application.

## Telephony Phone Book

### *TelPhbGetEntryCount*

---

← *oParamP*

A pointer to a [TelPhbGetEntryCountType](#) structure that is updated with information about the number of entries in the phone book.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                               |
| <code>transId</code>    | The transaction ID of the operation.                                                                                           |

| <code>functionId</code> | <code>kTelPhbGetEntryCountMessage</code>                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `oParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The total number of slots and the number of filled slots in the currently selected phone book are stored in the [TelPhbGetEntryCountType](#) structure referenced by `oParamP`.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

|            |                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------|
| paramP     | Points to the <a href="#">TelPhbGetEntryMaxSizesType</a> structure passed to this function in the oParamP parameter. |
| functionId | kTelPhbGetEntryMaxSizesMessage                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by oParamP remains in memory until the asynchronous call completes.

---

**Comments** The maximum size of any full name entry and the maximum size of any telephone number entry in the currently selected phone book are stored in the [TelPhbGetEntryMaxSizesType](#) structure referenced by oParamP.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetEntries\(\)](#), [TelPhbGetEntry\(\)](#)

## TelPhbGetSelectedPhonebook Function

**Purpose** Retrieve the ID of the currently selected phone book.

**Declared In** [TelephonyMgr.h](#)

**Prototype**

```
Err TelPhbGetSelectedPhonebook(UInt16 iRefnum,
    TelAppID iAppId, UInt8 *oPhbIdP,
    UInt16 *ioTransIdP)
```

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

← *oPhbIdP*

A pointer to an unsigned byte value. Upon return, this is filled in with the identifier of the currently selected phone book. The identifier is one of the [Phone Book Type Constants](#).

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                    |
| <code>transId</code>    | The transaction ID of the operation.                                                                |
| <code>paramP</code>     | Points to the unsigned integer value passed to this function in the <code>oPhbIdP</code> parameter. |
| <code>functionId</code> | <code>kTelPhbGetSelectedPhonebookMessage</code>                                                     |

# Internet Library

---

---

**WARNING!** The information in this chapter applies only to a very specific set of Palm, Inc. handhelds such as the Palm VII® running Palm OS® version 3.2 or later. You *must* check for the presence of the [Wireless Internet Feature Set](#) prior to using the Internet Library. *Never assume that the Internet Library is present on any given class of handheld.*

---

This chapter provides reference material for the Internet library API:

- [Internet Library Data Structures](#)
- [Internet Library Constants](#)
- [Internet Library Functions](#)

The header file `INetMgr.h` declares the Internet library API. For more information on the Internet library, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**WARNING!** In future OS versions, PalmSource, Inc. does not intend to support or provide backward compatibility for the Internet library API documented in this chapter.

---

## Internet Library Data Structures

### INetCompressionTypeEnum Enum

The `INetCompressionTypeEnum` enum indicates the type of compression used for data exchanged via a socket. One of these enumerated types is set as the value of the [inetSockSettingCompressionTypeID](#) socket setting (a read-only setting).

---

```
typedef enum {
inetCompressionTypeNone = 0,
inetCompressionTypeBitPacked,
inetCompressionTypeLZ77
} INetCompressionTypeEnum;
```

---

#### Value Descriptions

|                                           |                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>inetCompressionTypeNone</code>      | No compression.                                                                                                |
| <code>inetCompressionTypeBitPacked</code> | Custom 5-bit compression scheme. This is typically used for data sent from the Palm Web Clipping Proxy server. |
| <code>inetCompressionTypeLZ77</code>      | Not used; reserved for future use.                                                                             |

## INetConfigNameType Struct

The `INetConfigNameType` structure holds the name of an Internet library network **configuration**. A configuration is a set of specific values for the Internet library settings. The Internet library defines a set of built-in configuration aliases for common network setups. These aliases point to configurations instead of holding the actual values themselves. You can use an alias anywhere in the API you would use a configuration. System-defined configuration aliases are listed in “[Configuration Aliases](#)” on page 1768.

This structure is used in the functions [INetLibConfigIndexFromName\(\)](#), [INetLibConfigRename\(\)](#), and [INetLibConfigSaveAs\(\)](#).

---

```
#define inetConfigNameSize 32;

typedef struct {
Char name[inetConfigNameSize]; // name of configuration
} INetConfigNameType, *INetConfigNamePtr;
```

---

#### Field Description

|                   |                                             |
|-------------------|---------------------------------------------|
| <code>name</code> | A configuration name (up to 32 characters). |
|-------------------|---------------------------------------------|

## INetContentTypeEnum Enum

The INetContentTypeEnum enum specifies the type of content to be exchanged via a socket. One of these enumerated types is set as the value of the [inetSockSettingContentTypeID](#) socket setting (a read-only setting).

---

```
typedef enum {
    inetContentTypeTextPlain = 0,
    inetContentTypeTextHTML,
    inetContentTypeImageGIF,
    inetContentTypeImageJPEG,
    inetContentTypeApplicationCML,
    inetContentTypeImagePalmOS,
    inetContentTypeOther
} INetContentTypeEnum;
```

---

### Value Descriptions

|                               |                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------|
| inetContentTypeTextPlain      | Not used                                                                             |
| inetContentTypeTextHTML       | Not used                                                                             |
| inetContentTypeImageGIF       | Not used                                                                             |
| inetContentTypeImageJPEG      | Not used                                                                             |
| inetContentTypeApplicationCML | Compressed HTML content (format used by the Palm Web Clipping Proxy server and PQAs) |
| inetContentTypeImagePalmOS    | Palm OS® bitmap                                                                      |
| inetContentTypeOther          | Some undefined content type                                                          |

## INetHTTPAttrEnum Enum

The INetHTTPAttrEnum enum specifies HTTP request and response attributes that are set by [INetLibSockHTTPAttrSet\(\)](#) and returned by [INetLibSockHTTPAttrGet\(\)](#).

## Internet Library

### *INetHTTPAttrEnum*

---

---

```
typedef enum {

//-----
// Request only attributes
//-----
// The following are ignored unless going through a CTP proxy
→ inetHTTPAttrWhichPart, // (W) UInt32 (0 N)
inetHTTPAttrIncHTTP, // (W) UInt32 (Boolean) only applicable
    // when inetHTTPAttrConvAlgorithm set to ctpConvNone
inetHTTPAttrCheckMailHi, // (W) UInt32
inetHTTPAttrCheckMailLo, // (W) UInt32
inetHTTPAttrReqContentVersion, // (W) UInt32, desired content
    // version. Represented as 2 low bytes. Lowest
byte is
    // minor version, next higher byte is major
version.
//-----
---
// Response only attributes
//-----
---
// Server response info
inetHTTPAttrRspSize, // (R) UInt32, entire HTTP Response size
    // including header and data
inetHTTPAttrResult, // (R) UInt32 (ctpErrXXX when using CTP
Proxy)
inetHTTPAttrErrDetail, // (R) UInt32 (server/proxy err code
when
    // using CTP Proxy)
inetHTTPAttrReason, // (R) Char[]
// Returned entity attributes
inetHTTPAttrContentLength, // (R) UInt32
inetHTTPAttrContentLengthUncompressed, // (R) UInt32 (in
bytes)
inetHTTPAttrContentLengthUntruncated, //(R) UInt32
inetHTTPAttrContentVersion, // (R) UInt32, actual content
version.
    // Represented as 2 low bytes. Lowest byte is minor
    // version, next higher byte is major version.
inetHTTPAttrContentCacheID, // (R) UInt32, cacheID for this
item
inetHTTPAttrReqSize // (R) UInt32 size of request sent
} INetHTTPAttrEnum;
```

---

### Value Descriptions

|                                                    |                                                                                                                                                                                                                             |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetHTTPAttrWhichPart</code>                 | An index to the part of the response data desired, if the response data is partitioned into chunks. Write-only.                                                                                                             |
| <code>inetHTTPAttrIncHTTP</code>                   | A Boolean that, if set, causes HTTP header data to be included as part of the content when retrieving raw data. Applicable only when <code>inetSettingConvAlgorithm</code> is set to <code>ctpConvNone</code> . Write-only. |
| <code>inetHTTPAttrCheckMailHi</code>               | High-order byte of ID for checking mail. Write-only.                                                                                                                                                                        |
| <code>inetHTTPAttrCheckMailLo</code>               | Low-order byte of ID for checking mail. Write-only.                                                                                                                                                                         |
| <code>inetHTTPAttrReqContentVersion</code>         | Desired content version. Represented as 2 low bytes. Lowest byte is minor version, next higher byte is major version. Write-only.                                                                                           |
| <code>inetHTTPAttrRspSize</code>                   | Size of entire HTTP (header and data). Read-only.                                                                                                                                                                           |
| <code>inetHTTPAttrResult</code>                    | Transport protocol error code. Read-only.                                                                                                                                                                                   |
| <code>inetHTTPAttrErrDetail</code>                 | Server/proxy error code when using the Palm Web Clipping Proxy server. Read-only.                                                                                                                                           |
| <code>inetHTTPAttrReason</code>                    | Transport protocol error message. Read-only.                                                                                                                                                                                |
| <code>inetHTTPAttrContentLength</code>             | Size of response data. Read-only.                                                                                                                                                                                           |
| <code>inetHTTPAttrContentLengthUncompressed</code> | Size of uncompressed response data. Read-only.                                                                                                                                                                              |
| <code>inetHTTPAttrContentLengthUntruncated</code>  | Total size of response data (it may have been truncated to less than this). Read-only.                                                                                                                                      |

## Internet Library

### *INetSchemeEnum*

---

|                                         |                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>inetHTTPAttrContentVersion</code> | Actual content version. Represented as 2 low bytes. Lowest byte is minor version, next higher byte is major version. Read-only. |
| <code>inetHTTPAttrContentCacheID</code> | Cache ID for this item. Read-only.                                                                                              |
| <code>inetHTTPAttrReqSize</code>        | Size of request sent. Read-only.                                                                                                |

## INetSchemeEnum Enum

The `INetSchemeEnum` enum specifies a protocol (http, https, etc.) used by a socket. Specify one of these enumerated types for the `INetSockSettingScheme` socket setting and for the scheme parameter to the [`INetLibSockOpen\(\)`](#) call.

---

```
typedef enum {
inetSchemeUnknown = -1,
inetSchemeDefault = 0,    // not used

inetSchemeHTTP, // http:
inetSchemeHTTPS, // https:
inetSchemeFTP, // ftp:
inetSchemeGopher, // gopher:
inetSchemeFile, // file:
inetSchemeNews, // news:
inetSchemeMailTo, // mailto:
inetSchemePalm, // palm:
inetSchemePalmCall, // palmcall:
inetSchemeMail, // not applicable to URLs, but used
                    // for the INetLibSockOpen call when
                    // creating a socket for mail IO
inetSchemeMac, // mac: - Mac file system HTML

inetSchemeFirst = inetSchemeHTTP, // first one
inetSchemeLast = inetSchemeMail // last one
} INetSchemeEnum;
```

---

## Value Descriptions

|                              |                                                   |
|------------------------------|---------------------------------------------------|
| <code>inetSchemeHTTP</code>  | Use the HTTP protocol.                            |
| <code>inetSchemeHTTPS</code> | Use the HTTPS protocol (for a secure connection). |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSchemeFTP</code>      | Use the FTP protocol. Not implemented.                                                                                                                                                                                                                                                                                                                                               |
| <code>inetSchemeGopher</code>   | Use the Gopher protocol. Not implemented.                                                                                                                                                                                                                                                                                                                                            |
| <code>inetSchemeFile</code>     | Launch local PQA file                                                                                                                                                                                                                                                                                                                                                                |
| <code>inetSchemeNews</code>     | Use the News protocol. Not implemented.                                                                                                                                                                                                                                                                                                                                              |
| <code>inetSchemeMailTo</code>   | Launch the local messaging application, passing a “to” address.                                                                                                                                                                                                                                                                                                                      |
| <code>inetSchemePalm</code>     | Launches a local application database. The URL is expected to be in the form <code>cccc.tttt</code> , where <code>cccc</code> is a four character creator name and <code>tttt</code> is a four character database type. This pair of strings is used to identify an application database to receive the launch message via a call to <a href="#"><code>SysUIAppSwitch()</code></a> . |
| <code>inetSchemePalmCall</code> | Launches a local application database. The URL is expected to be in the form <code>cccc.tttt</code> , where <code>cccc</code> is a four character creator name and <code>tttt</code> is a four character database type. This pair of strings is used to identify an application database to receive the launch message via a call to <a href="#"><code>SysAppLaunch()</code></a> .   |
| <code>inetSchemeMail</code>     | Creates a socket for mail I/O.                                                                                                                                                                                                                                                                                                                                                       |
| <code>inetSchemeMac</code>      | Handles opening Mac OS file system HTML URLs. For use by the Simulator only.                                                                                                                                                                                                                                                                                                         |

## INetSettingEnum Enum

The `INetSettingEnum` enum specifies a setting to be returned or set by the [`INetLibSettingGet\(\)`](#) or [`INetLibSettingSet\(\)`](#) calls.

---

```
typedef enum {  
    inetSettingCacheSize, // (RW) UInt32, max size of cache  
    inetSettingCacheRef, // (R) DmOpenRef, ref of cache DB  
    inetSettingNetLibConfig, // (RW) UInt32, NetLib config to use  
    inetSettingRadioID, // (R) UInt32[2], the 64-bit radio ID  
    inetSettingBaseStationID, // (R) UInt32, the radio base  
        station Id  
    inetSettingMaxRspSize, // (W) UInt32 (in bytes)
```

## Internet Library

### *INetSettingEnum*

---

```
inetSettingConvAlgorithm, // (W) UInt32 (CTPConvEnum)
inetSettingContentWidth, // (W) UInt32 (in pixels)
inetSettingContentVersion, // (W) UInt32, content version
(encoder                                     // version)
inetSettingNoPersonalInfo, // (RW) UInt32, send no deviceID/
zipcode
inetSettingUserName,
inetSettingLast
} INetSettingEnum;
```

---

### Value Descriptions

|                                       |                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSettingCacheSize</code>     | Maximum size of cache (in bytes).                                                                                                                                                                                                                                                                                                                                        |
| <code>inetSettingCacheRef</code>      | <code>DmOpenRef</code> , reference to cache database. Read-only.                                                                                                                                                                                                                                                                                                         |
| <code>inetSettingNetLibConfig</code>  | The index of the net library network configuration to use. This value is saved as part of the preferences for each Internet library configuration. A value of 0 means to use the current configuration.                                                                                                                                                                  |
| <code>inetSettingRadioID</code>       | 64-bit radio ID. Read-only. Used for wireless connections only.                                                                                                                                                                                                                                                                                                          |
| <code>inetSettingBaseStationID</code> | Radio base station ID. Read-only. Used for wireless connections only.                                                                                                                                                                                                                                                                                                    |
| <code>inetSettingMaxRspSize</code>    | Maximum response size, in bytes. The default is 1024 bytes. Write-only.                                                                                                                                                                                                                                                                                                  |
| <code>inetSettingConvAlgorithm</code> | Content conversion desired. Write-only. Possible values include:<br><code>ctpConvCML</code> (use 5-bit compression scheme),<br><code>ctpConvCML8Bit</code> (use 5-bit compression scheme, but in 8-bit form for debugging),<br><code>ctpConvCMLLZ77</code> (use LZ77 compression scheme),<br><code>ctpConvNone</code> (no conversion; data is returned in native format) |

|                                        |                                                                                                                                                                                                                                                                                                              |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSettingContentWidth</code>   | Width of the display for content. The default setting is 160 (pixels). Write-only.                                                                                                                                                                                                                           |
| <code>inetSettingContentVersion</code> | Content version (encoder version). Write-only. This setting is used to let the server know what encoder version it should use to encode content sent to the Palm client. Normally you don't need to set this value as it is initialized by <code>INetLibOpen</code> . The default encoder version is 0x8001. |
| <code>inetSettingNoPersonalInfo</code> | Send no device ID or zipcode information to the proxy server. This value is saved as part of the preferences for each Internet library configuration.                                                                                                                                                        |
| <code>inetSettingUserName</code>       | Not applicable.                                                                                                                                                                                                                                                                                              |

## INetSockSettingEnum Enum

The `INetSockSettingEnum` enum specifies a socket setting to be returned or set by the [`INetLibSockSettingGet\(\)`](#) or [`INetLibSockSettingSet\(\)`](#) calls.

---

```
typedef enum {
inetSockSettingScheme, // (R) UInt32, INetSchemeEnum
inetSockSettingSockContext, // (RW) UInt32,
inetSockSettingCompressionType, // (R) Char[]
inetSockSettingCompressionTypeID, // (R) UInt32
                                     //
    (INetCompressionTypeEnum)
inetSockSettingContentType, // (R) Char[]
inetSockSettingContentTypeID, // (R) UInt32
    (INetContentTypeEnum)
inetSockSettingData, // (R) UInt32, pointer to data
inetSockSettingDataHandle, // (R) UInt32, handle to data
inetSockSettingDataOffset, // (R) UInt32, offset to data from
    handle
inetSockSettingTitle, // (W) Char[]
inetSockSettingURL, // (R) Char[]
inetSockSettingIndexURL, // (RW) Char[]
inetSockSettingFlags, // (RW) UInt16, one or more of
    // inetOpenURLFlagXXX flags
inetSockSettingReadTimeout, // (RW) UInt32, read timeout in
    ticks
}
```

```
inetSockSettingContentVersion, // (R) UInt32, content version
number
inetSockSettingLast
} INetSockSettingEnum;
```

---

#### Value Descriptions

|                                  |                                                                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inetSockSettingScheme            | Requested scheme; one of the <a href="#">INetSchemeEnum</a> values. Read-only.                                                                             |
| inetSockSettingSockContext       | Not used.                                                                                                                                                  |
| inetSockSettingCompressionType   | Name of requested compression type. Read-only.                                                                                                             |
| inetSockSettingCompressionTypeID | Requested compression type; one of the <a href="#">INetCompressionTypeEnum</a> values. Read-only.                                                          |
| inetSockSettingContentType       | String containing the MIME type of the content. Used only on received raw data. Read-only.                                                                 |
| inetSockSettingContentTypeID     | Content type of socket data; one of the <a href="#">INetContentTypeEnum</a> values. Read-only.                                                             |
| inetSockSettingData              | Pointer to socket data. Read-only.                                                                                                                         |
| inetSockSettingDataHandle        | Handle to socket data. Read-only.                                                                                                                          |
| inetSockSettingDataOffset        | Offset to socket data from handle. Read-only.                                                                                                              |
| inetSockSettingTitle             | Web page title. This value is written to the cache (and the Web Clipping Application Viewer uses it later in a history list of cache entries). Write-only. |
| inetSockSettingURL               | URL of requested data. Read-only.                                                                                                                          |

|                                            |                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSockSettingIndexURL</code>       | Index (or master) URL of requested data (for cache indexing). This is the topmost web page in a group of hierarchical pages; it serves to group the pages together and to filter cache list results. The Web Clipping Application Viewer sets this to the URL of the active PQA, for all pages linked from the PQA. |
| <code>inetSockSettingFlags</code>          | URL request flags; one or more of <code>inetOpenURLFlag...</code> flags (see <a href="#">URL Open Constants</a> ).                                                                                                                                                                                                  |
| <code>inetSockSettingReadTimeout</code>    | The default timeout value for reads when the application uses the event mechanism. The time since last receiving data from a socket is monitored and a timeout error status event is returned from <code>INetLibGetEvent</code> if the timeout is exceeded.                                                         |
| <code>inetSockSettingContentVersion</code> | Content version number. Read-only.                                                                                                                                                                                                                                                                                  |

## INetStatusEnum Enum

The `INetStatusEnum` enum specifies the status of the socket. The status is returned in the [inetSockStatusChangeEvent](#) event structure and by the call [INetLibSockStatus\(\)](#).

---

```
typedef enum {  
    inetStatusNew, // just opened  
    inetStatusResolvingName, // looking up host address  
    inetStatusNameResolved, // found host address  
    inetStatusConnecting, // connecting to host  
    inetStatusConnected, // connected to host  
    inetStatusSendingRequest, // sending request  
    inetStatusWaitingForResponse, // waiting for response  
    inetStatusReceivingResponse, // receiving response  
    inetStatusResponseReceived, // response received  
    inetStatusClosingConnection, // closing connection  
    inetStatusClosed, // closed  
}
```

## Internet Library

### *Internet Library Constants*

---

```
inetStatusAcquiringNetwork, // network temporarily
                             // unreachable; socket on
hold
inetStatusPrvInvalid = 30 // internal value, not returned by
                             // INetMgr. Should be
last.
} INetStatusEnum;
```

---

#### Value Descriptions

|                              |                                                 |
|------------------------------|-------------------------------------------------|
| inetStatusNew                | Just opened                                     |
| inetStatusResolvingName      | Looking up host address                         |
| inetStatusNameResolved       | Found host address                              |
| inetStatusConnecting         | Connecting to host                              |
| inetStatusConnected          | Connected to host                               |
| inetStatusSendingRequest     | Sending request                                 |
| inetStatusWaitingForResponse | Waiting for response                            |
| inetStatusReceivingResponse  | Receiving response                              |
| inetStatusResponseReceived   | Response received                               |
| inetStatusClosingConnection  | Closing connection                              |
| inetStatusClosed             | Connection closed                               |
| inetStatusAcquiringNetwork   | Network temporarily unreachable; socket on hold |
| inetStatusPrvInvalid         | Not used                                        |

## Internet Library Constants

### Configuration Aliases

The constants listed here specify Internet library network configuration alias names. Most of the Internet library API requires a configuration index rather than a name. Use

[INetLibConfigIndexFromName\(\)](#) to obtain the alias's index from the name. For more information, see [INetConfigNameType](#).

The following aliases are defined for configuration names:

| Alias                               | Name string                 | Description                                                                                                                                                                                                                                 |
|-------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetCfgNameDefault</code>     | <code>".Default"</code>     | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameDefWireline</code> | <code>".DefWireline"</code> | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameDefWireless</code> | <code>".DefWireless"</code> | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameCTPDefault</code>  | <code>".CTPDefault"</code>  | Initially points to either <code>".CTPWireless"</code> (on Palm VII <sup>®</sup> units) or <code>".CTPWireline"</code> (on all other units). On the Palm VII unit, the Web Clipping Application Viewer application uses this configuration. |
| <code>inetCfgNameCTPWireline</code> | <code>".CTPWireline"</code> | Initially points to a wireline configuration that uses the Palm Web Clipping Proxy server.                                                                                                                                                  |
| <code>inetCfgNameCTPWireless</code> | <code>".CTPWireless"</code> | Initially points to a wireless configuration that uses the Palm.Net <sup>™</sup> wireless system and the Palm Web Clipping Proxy server.                                                                                                    |

## URL Info Constants

The `inetURLInfoFlag...` constants convey information about a URL and are returned by the function [`INetLibURLGetInfo\(\)`](#).

| Constant                              | Value  | Description                     |
|---------------------------------------|--------|---------------------------------|
| <code>inetURLInfoFlagIsSecure</code>  | 0x0001 | URL was encrypted.              |
| <code>inetURLInfoFlagIsRemote</code>  | 0x0002 | URL was retrieved from the net. |
| <code>inetURLInfoFlagIsInCache</code> | 0x0004 | URL is stored in the cache.     |

## URL Open Constants

The `inetOpenURLFlag...` constants control how the [`INetLibURLOpen\(\)`](#) call operates with respect to caching and encryption. These flags are also used for the [`inetSockSettingFlags`](#) socket setting.

| Constant                                | Value  | Description                                                                        |
|-----------------------------------------|--------|------------------------------------------------------------------------------------|
| <code>inetOpenURLFlagLookInCache</code> | 0x0001 | Read data from the cache, if available.                                            |
| <code>inetOpenURLFlagKeepInCache</code> | 0x0002 | Store the item in the cache, overwriting any other entries with an equivalent URL. |
| <code>inetOpenURLFlagForceEncOn</code>  | 0x0008 | Use encryption even if scheme does not desire it.                                  |
| <code>inetOpenURLFlagForceEncOff</code> | 0x0010 | Do not use encryption even if scheme desires it.                                   |

## Internet Library Functions

### INetLibCacheGetObject Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |          |                      |                                            |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|----------|----------------------|--------------------------------------------|
| <b>Purpose</b>       | Returns information about an entry in the cache database, including a handle to the record. Either the URL or the unique ID can be used to find the cache entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |          |                      |                                            |
| <b>Declared In</b>   | INetMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |          |                      |                                            |
| <b>Prototype</b>     | <pre>Err INetLibCacheGetObject (UInt16 libRefnum,     MemHandle clientParamH, UInt8 *urlTextP,     UInt32 uniqueID, INetCacheInfoPtr cacheInfoP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |   |          |                      |                                            |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>Refnum of the Internet library.</p> <p>→ <i>clientParamH</i><br/>Inet handle allocated by INetLibOpen.</p> <p>→ <i>urlTextP</i><br/>Pointer to URL text string to find. If this parameter is NULL, then uniqueID is used to find the entry.</p> <p>→ <i>uniqueID</i><br/>Unique ID of the cache entry to find. This value can be obtained by calling <a href="#">INetLibCacheList()</a>. This parameter is ignored if urlTextP is specified.</p> <p>← <i>INetCacheInfoPtr</i><br/>Pointer to a structure where information about the cache entry is returned. See the Comments section for details.</p> |   |          |                      |                                            |
| <b>Returns</b>       | <table> <tr> <td>0</td><td>No error</td></tr> <tr> <td>inetErrParamsInvalid</td><td>One or more of the parameters are invalid.</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 0 | No error | inetErrParamsInvalid | One or more of the parameters are invalid. |
| 0                    | No error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |   |          |                      |                                            |
| inetErrParamsInvalid | One or more of the parameters are invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |   |          |                      |                                            |
| <b>Comments</b>      | The INetCacheInfoPtr type returned from this function is defined as a pointer to an INetCacheInfoType structure, which has the following definition:                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |          |                      |                                            |
| <b>Prototype</b>     | <pre>typedef struct {     MemHandle recordH; // handle to the cache record</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |   |          |                      |                                            |

## Internet Library

### *INetLibCacheList*

---

```
INetContentTypeEnum contentType;
INetCompressionTypeEnum encodingType;
UInt32 uncompressedDataSize;
UInt8 flags; // unused
UInt8 reserved;
UInt16 dataOffset; // offset to content
UInt16 dataLength; // size of content
UInt16 urlOffset; // offset to URL
UInt32 viewTime; // time last viewed
UInt32 createTime; // time entry was created
UInt16 murlOffset; // offset to master URL
} INetCacheInfoType, *INetCacheInfoPtr;
```

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibCacheList Function

**Purpose** Returns an item from the cache list, based on its URL and index in the list.

**Declared In** *INetMgr.h*

**Prototype**

```
Err INetLibCacheList (UInt16 libRefnum,
    MemHandle inetH, UInt8 *cacheIndexURLP,
    UInt16 *indexP, UInt32 *uidP,
    INetCacheEntryP cacheP)
```

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *inetH*  
Inet handle allocated by *INetLibOpen*.
- *cacheIndexURLP*  
Pointer to a master URL string. Cache entries indexed with this master URL are returned. The Web Clipping Application Viewer sets the master URL of a cache page to the URL of the active PQA, so all pages linked from the PQA have the same master URL.
- ↔ *indexP*  
Pointer to the index of the entry. Specify an index to find entries at this index or higher in the list. Specify NULL to search from the beginning, the first time you call this

function. The index of the entry following the one found is returned on exit.

← *uidP*

Pointer to a long value where the unique ID of the found cache entry is returned.

← *cacheP*

Pointer to a structure where information about the found cache entry is returned. See the Comments section for details.

### Returns

|                                   |                                                   |
|-----------------------------------|---------------------------------------------------|
| 0                                 | No error                                          |
| <code>inetErrTypeNotCached</code> | Cache entry under requested index not found       |
| <code>inetErrParamsInvalid</code> | The <code>cacheIndexURLP</code> parameter is NULL |
| <code>inetErrCacheInvalid</code>  | The cache database doesn't exist                  |

### Comments

This function first sorts the list of cache entries by URL. Then it returns in *uidP* the unique ID of the first cache entry with an index equal to or greater than *indexP*. The *indexP* value is updated to point to the next entry upon return.

To generate a complete list of cache entries having the same master URL (as for a history list), call this function repeatedly, always specifying the updated *index*, until it returns the error `inetErrTypeNotCached`.

Note that a URL can exist multiple times in the Web Clipping Application Viewer cache database, thus the need for the *uidP* value.

The `INetCacheEntryP` type returned from this function is defined as a pointer to an `INetCacheEntryType` structure, which has the following definition:

---

```
typedef struct {
    UInt8 *urlP; // ptr to URL string
    UInt16 urlLen; // length of URL string
    UInt8 *titleP; // ptr to title string
    UInt16 titleLen; // length of title string
    UInt32 lastViewed; // time last viewed
                  // seconds since 1/1/1904
```

## Internet Library

### *INetLibCheckAntennaState*

---

```
UInt32 firstViewed; // time first viewed
                // seconds since 1/1/1904
} INetCacheEntryType, *INetCacheEntryP;
```

---

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## **INetLibCheckAntennaState Function**

**Purpose** Checks the antenna state and displays a dialog asking the user to raise it if it is down.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibCheckAntennaState(UInt16 refNum)`

**Parameters**  $\rightarrow$  *refNum*  
Refnum of the Internet library.

### **Returns**

|                               |                                               |
|-------------------------------|-----------------------------------------------|
| 0                             | The user raised the antenna.                  |
| <code>netErrUserCancel</code> | The user closed the dialog by tapping Cancel. |

This call can also return data manager errors if it fails internally.

**Comments** Applications don't need to check the antenna state by using this call. If an application opens the Internet library, the Internet library checks the antenna state when needed and displays the dialog to prompt the user to raise the antenna.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibClose Function

|                      |                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Closes up and frees an inet handle. Closes or decrements the open count of the net library.                                                                                                                                                                                                    |
| <b>Declared In</b>   | INetMgr.h                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>     | Err INetLibClose (UInt16 libRefnum,<br>MemHandle inetH)                                                                                                                                                                                                                                        |
| <b>Parameters</b>    | → <i>libRefnum</i><br>Refnum of the Internet library.<br><br>→ <i>inetH</i><br>Inet handle allocated by INetLibOpen.                                                                                                                                                                           |
| <b>Returns</b>       | 0 No error                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>      | This call must be made by an application when it's done with the Internet library. It closes any Internet sockets open by the application, disposes the memory referenced by the given inet handle, and calls NetLibClose, if necessary, to close the net Library or decrement its open count. |
| <b>Compatibility</b> | Implemented only if <a href="#">Wireless Internet Feature Set</a> is present.                                                                                                                                                                                                                  |
| <b>See Also</b>      | <a href="#">INetLibOpen()</a>                                                                                                                                                                                                                                                                  |

## INetLibConfigAliasGet Function

|                    |                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Determines to which configuration a built-in alias points.                                                                                                                                                                                                                       |
| <b>Declared In</b> | INetMgr.h                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | Err INetLibConfigAliasGet (UInt16 refNum,<br>UInt16 aliasIndex, UInt16 *indexP,<br>Boolean *isAnotherAliasP)                                                                                                                                                                     |
| <b>Parameters</b>  | → <i>libRefnum</i><br>Refnum of the Internet library.<br><br>→ <i>aliasIndex</i><br>Index of alias configuration to query. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the |

array returned by [INETLibConfigList\(\)](#), or the index returned by [INETLibConfigIndexFromName\(\)](#).

← *indexP*

Pointer where the index of the configuration pointed to by *aliasIndex* is returned. 0 is returned if *aliasIndex* does not point to another configuration.

← *isAnotherAliasP*

If *\*indexP* is the index of another alias configuration, this Boolean is set to true.

### Returns

|                       |                                                 |
|-----------------------|-------------------------------------------------|
| 0                     | No error                                        |
| inetErrParamsInvalid  | <i>aliasIndex</i> is not valid                  |
| inetErrConfigNotAlias | <i>aliasIndex</i> is not an alias configuration |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INETLibConfigAliasSet\(\)](#)

## INETLibConfigAliasSet Function

**Purpose** Points any of the built-in aliases (".DefWireline", ".DefWireless", etc.) to a given defined configuration.

**Declared In** `INETMgr.h`

**Prototype** `Err INetLibConfigAliasSet (UInt16 refNum,  
 UInt16 configIndex, UInt16 aliasToIndex)`

**Parameters** → *libRefnum*  
 Refnum of the Internet library.

→ *configIndex*  
 Index of configuration to set. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by [INETLibConfigList\(\)](#), or the index returned by [INETLibConfigIndexFromName\(\)](#).

→ *aliasToIndex*

Index of configuration that the alias identified by `configIndex` is to point to. Specify 0 to remove an existing alias assignment.

**Returns**

|                                            |                                                                    |
|--------------------------------------------|--------------------------------------------------------------------|
| 0                                          | No error                                                           |
| <code>inetErrConfigNotAlias</code>         | <code>configIndex</code> is not an alias configuration             |
| <code>inetErrParamsInvalid</code>          | <code>configIndex</code> or <code>aliasToIndex</code> is not valid |
| <code>inetErrConfigCantPointToAlias</code> | Alias doesn't point to a real entry                                |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibConfigAliasGet\(\)](#)

## INetLibConfigDelete Function

**Purpose** Deletes a configuration.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigDelete (UInt16 refNum, UInt16 index)`

**Parameters** → *refnum*

Refnum of the Internet library.

→ *index*

Index of configuration to delete. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by [INetLibConfigList\(\)](#), or the index returned by [INetLibConfigIndexFromName\(\)](#).

**Returns**

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

## Internet Library

### *INetLibConfigIndexFromName*

---

|                                      |                                            |
|--------------------------------------|--------------------------------------------|
| <code>inetErrParamsInvalid</code>    | Index not valid                            |
| <code>inetErrConfigCantDelete</code> | Attempted to delete an alias configuration |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibConfigIndexFromName\(\)](#), [INetLibConfigList\(\)](#)

## INetLibConfigIndexFromName Function

**Purpose** Returns the index of a configuration given it's name.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigIndexFromName (UInt16 refNum,  
INetConfigNamePtr nameP, UInt16 *indexP)`

**Parameters**

- *refnum*  
Refnum of the Internet library.
- *nameP*  
Pointer to an [INetConfigNameType](#) structure that names the configuration whose index you want to get.
- ← *indexP*  
Pointer where the index of the configuration identified in *nameP* is returned.

**Returns**

|                                    |                                             |
|------------------------------------|---------------------------------------------|
| 0                                  | No error                                    |
| <code>inetErrConfigNotFound</code> | Could not find requested configuration name |

**Comments** If you name an alias, this routine returns the index of the alias entry, not the configuration the alias points to. This way the alias can be pointed to a different configuration.

Applications should store the index of the configuration they're using, rather than the name, so that they won't be confused if the user edits the name of the configuration from the Preferences panel.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibConfigList\(\)](#)

## INetLibConfigList Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns an array containing a list of the available Internet library network configurations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b>   | <code>INetMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <pre>Err INetLibConfigList (UInt16 refNum,<br/>    INetConfigNameType nameArray[],<br/>    UInt16 *arrayEntriesP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>    | <p>→ <i>refnum</i><br/>Refnum of the Internet library.</p> <p>→ <i>nameArray</i><br/>Pointer to an array of <a href="#">INetConfigNameType</a> structs that is to be filled in by this routine.</p> <p>↔ <i>arrayEntriesP</i><br/>On entry, a pointer to the number of entries available in <i>nameArray</i>; on exit, a pointer to the total number of entries in the system (which could exceed the size of the array you pass in).</p>                                                                                                                                                                                                 |
| <b>Returns</b>       | 0 No error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>      | <p>This routine can be used to obtain a list of available configurations for selection by the user.</p> <p>Note that the built-in alias configurations, which start with a period, should not be displayed to the user as selectable choices. They are designed for internal use by applications that need a predetermined type of service (like ".CTPWireless" for PQA applications.) Also, any configurations that start with an underscore, like "_CTPRAM", should not be displayed. These typically are configurations created by the Internet library for internal use and cannot be edited using the Network preferences panel.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">Wireless Internet Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>See Also</b>      | <a href="#">INetLibConfigMakeActive()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## INetLibConfigMakeActive Function

|                |                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Makes the given configuration active without having to close and reopen the Internet library by using <code>INetLibOpen</code> . |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|

**Declared In** `INetMgr.h`

[illegible]

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *inetH*  
Inet handle allocated by `INetLibOpen`.
- *configIndex*  
Index of configuration to activate. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by `INetLibConfigList()`, or the index returned by `INetLibConfigIndexFromName()`.

## Returns

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [InetLibConfigSaveAs\(\)](#), [InetLibConfigList\(\)](#), [InetLibConfigIndexFromName\(\)](#)

## INetLibConfigRename Function

|                |                          |
|----------------|--------------------------|
| <b>Purpose</b> | Renames a configuration. |
|----------------|--------------------------|

**Declared In** `INetMgr.h`

[illegible]

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *index*  
Index of configuration to rename. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the

array returned by [INetLibConfigList\(\)](#), or the index returned by [INetLibConfigIndexFromName\(\)](#).

→ *newNameP*

Pointer to an [INetConfigNameType](#) structure holding the new name of the configuration. The name cannot start with a period or an underscore.

### Returns

|                         |                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------|
| 0                       | No error                                                                                             |
| inetErrConfigBadName    | Trying to save as an alias (beginning with ".") or as a built-in configuration (beginning with "-"). |
| inetErrParamsInvalid    | Invalid index                                                                                        |
| inetErrConfigCantDelete | Configuration to be renamed is either an alias or a built-in configuration                           |

**Comments** After renaming, the configuration index stays the same so that applications that are set up to use that configuration will still work correctly. Note that built-in configuration aliases (ones that start with a period) cannot be renamed.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibConfigSaveAs Function

**Purpose** Saves the current network configuration settings under the given name.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigSaveAs (UInt16 refNum,  
MemHandle inetH, INetConfigNamePtr nameP)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *inetH*  
Inet handle allocated by `INetLibOpen`.

## Internet Library

### *INetLibGetEvent*

---

→ *nameP*

Pointer to an [INetConfigNameType](#) structure holding the name of the configuration. The name cannot start with a period or an underscore.

#### Returns

|                                   |                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------|
| 0                                 | No error                                                                                             |
| <code>inetErrConfigBadName</code> | Trying to save as an alias (beginning with ".") or as a built-in configuration (beginning with "_"). |
| <code>inetErrConfigTooMany</code> | The internal configurations table is full. No more entries can be stored.                            |

**Comments** If the configuration name specified already exists, it is replaced with the new settings.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibGetEvent Function

**Purpose** A replacement for `EvtGetEvent` that informs an application of status changes to Internet sockets as well as user interface events.

**Declared In** `INetMgr.h`

**Prototype** `void INetLibGetEvent (UInt16 libRefnum,  
MemHandle inetH, INetEventType *eventP,  
Int32 timeout)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *inetH*  
Inet handle allocated by `INetLibOpen`, or `NULL`.
- ↔ *eventP*  
The event structure is returned via this pointer.
- *timeout*  
Timeout in ticks. Specify `evtWaitForever` to wait forever.

#### Returns

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | <p>This call is designed to replace <a href="#">EvtGetEvent()</a> in applications which use the Internet library. For convenience, if <code>inetH</code> is <code>NULL</code>, <code>INetLibGetEvent</code> is equivalent to <code>EvtGetEvent</code>.</p> <p><code>INetLibGetEvent</code> returns two additional events besides those returned by <code>EvtGetEvent</code>: <a href="#">inetSockReadyEvent</a> and <a href="#">inetSockStatusChangeEvent</a>.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">Wireless Internet Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>See Also</b>      | <a href="#">INetLibSockStatus()</a> , <a href="#">INetLibURLOpen()</a> ,<br><a href="#">INetLibSockOpen()</a> , <a href="#">INetLibSockRead()</a>                                                                                                                                                                                                                                                                                                                  |

## INetLibOpen Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Creates a new application inet handle structure. Opens or increments the open count of the net library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>INetMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <pre>Err INetLibOpen (UInt16 libRefnum, UInt16 config,                 UInt32 flags, DmOpenRef cacheRef,                 UInt32 cacheSize, MemHandle *inetHP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>Refnum of the Internet library. Pass the value "INet.lib" to <a href="#">SysLibFind()</a> to return this refnum.</p> <p>→ <i>config</i><br/>Indicates the type of network service desired by the application. Returned by <a href="#">INetLibConfigIndexFromName()</a>.</p> <p>→ <i>flags</i><br/>Currently unused; set to 0.</p> <p>→ <i>cacheRef</i><br/>Document cache database reference. Obtain this by using one of the <a href="#">DmOpenDatabase()</a>... calls. Pass <code>NULL</code> if you don't want to use a cache.</p> <p>→ <i>cacheSize</i><br/>Maximum size of the document cache (in bytes). This is ignored if you pass <code>NULL</code> for <i>cacheRef</i>.</p> <p>← <i>inetHP</i><br/>Pointer to a handle variable.</p> |

## Internet Library

### *INetLibSettingGet*

---

#### Returns

|                                           |                                                                |
|-------------------------------------------|----------------------------------------------------------------|
| 0                                         | No error                                                       |
| <code>inetErrTooManyClients</code>        | Too many clients opened already                                |
| <code>inetErrIncompatibleInterface</code> | The net library is already open with an incompatible interface |

#### Comments

This call must be made by an application before it can use any other Internet library calls. This call opens the Internet library and returns a pointer to an inet handle, which is then passed to subsequent calls to the Internet library. Every application that opens the Internet library gets its own unique inet handle.

When an application is done using the Internet library, it must call [INetLibClose\(\)](#), which closes both the Internet library and the net library, if necessary.

#### Compatibility

Implemented only if [Wireless Internet Feature Set](#) is present.

#### See Also

[INetLibClose\(\)](#), [INetLibConfigIndexFromName\(\)](#)

## INetLibSettingGet Function

#### Purpose

Retrieves current settings for an inet handle.

#### Declared In

`INetMgr.h`

#### Prototype

```
Err INetLibSettingGet (UInt16 libRefnum,  
    MemHandle inetH, UInt16 setting, void *bufP,  
    UInt16 *bufLenP)
```

#### Parameters

→ *libRefnum*  
Refnum of the Internet library.

→ *inetH*  
Inet handle allocated by `INetLibOpen`.

→ *setting*  
The setting to get. Specify one of the [INetSettingEnum](#) enumerated types.

← *bufP*  
Pointer to buffer where the return value is to be put.

↔ *bufLenP*

Size of *bufP* on entry. Size of setting value on exit.

**Returns**

0

No error

*inetErrParamsInvalid*

Invalid setting requested

*inetErrSettingSizeInvalid*

\**bufLenP* is the incorrect size for the requested setting

**Comments**

This call can be used to retrieve the current settings of an inet handle. Some settings have default values that are stored in the system preferences database; see [INetSettingEnum](#) for details.

**Compatibility**

Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**

[INetLibOpen\(\)](#), [INetLibSettingSet\(\)](#), [INetSettingEnum](#)

## INetLibSettingSet Function

**Purpose**

Changes a setting for an inet handle.

**Declared In**

*INetMgr.h*

**Prototype**

```
Err INetLibSettingSet (UInt16 libRefnum,
    MemHandle inetH, UInt16 setting, void *bufP,
    UInt16 bufLen)
```

**Parameters**

→ *libRefnum*

Refnum of the Internet library.

→ *inetH*

Inet handle allocated by *INetLibOpen*.

→ *setting*

The setting to set. Specify one of the [INetSettingEnum](#) enumerated types.

→ *bufP*

Pointer to the new setting value.

→ *bufLen*

Size of the value in *bufP*.

## Internet Library

### *INetLibSockClose*

---

#### Returns

|                                        |                                                                     |
|----------------------------------------|---------------------------------------------------------------------|
| 0                                      | No error                                                            |
| <code>inetErrParamsInvalid</code>      | Invalid setting specified                                           |
| <code>inetErrSettingSizeInvalid</code> | <code>bufLen</code> is the incorrect size for the specified setting |

#### Comments

Any changes made to the settings last only as long as the `inetH` is around (until [INetLibClose\(\)](#) is called) and do not affect other applications that might be using the Internet library.

An important note is that settings made through this call essentially change the default values for any sockets subsequently created through [INetLibURLOpen\(\)](#) or [INetLibSockOpen\(\)](#).

#### Compatibility

Implemented only if [Wireless Internet Feature Set](#) is present.

#### See Also

[INetLibSettingGet\(\)](#), [INetSettingEnum](#)

## INetLibSockClose Function

#### Purpose

Closes an inet socket handle.

#### Declared In

`INetMgr.h`

#### Prototype

```
Err INetLibSockClose (UInt16 libRefnum,  
                     MemHandle socketH)
```

#### Parameters

→ *libRefnum*  
Refnum of the Internet library.

→ *socketH*  
Handle of the socket to close.

#### Returns

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

#### Comments

This call closes down and releases all memory associated with a socket created by `INetLibSockOpen` or `INetLibURLOpen`.

#### Compatibility

Implemented only if [Wireless Internet Feature Set](#) is present.

#### See Also

[INetLibOpen\(\)](#), [INetLibSockOpen\(\)](#), [INetLibURLOpen\(\)](#)

## INetLibSockConnect Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Establishes a connection with a remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b>   | INetMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>     | <pre>Err INetLibSockConnect (UInt16 libRefnum,<br/>                        MemHandle sockH, UInt8 *hostnameP,<br/>                        UInt16 port,<br/>                        Int32 timeou)</pre>                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>Refnum of the Internet library.</p> <p>→ <i>sockH</i><br/>Handle (allocated by INetLibSockOpen or<br/>INetLibURLOpen) of the socket to connect.</p> <p>→ <i>hostnameP</i><br/>Pointer to host name string; can be dotted decimal text string.</p> <p>→ <i>port</i><br/>Port number, or 0 for default port.</p> <p>→ <i>timeou</i><br/>Timeout in ticks. Specify evtWaitForever to wait forever.</p>                                                                                                                                                                                  |
| <b>Returns</b>       | <p>0 No error</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>      | <p>This call associates a remote host name and port number with a socket and, depending on the socket protocol, initiates a connection with that remote host.</p> <p>This call may return immediately before actually finishing the connect. The application can simply go ahead and submit additional calls such as INetLibSockRead, or it may wait for the connect to complete by either polling INetLibSockStatus until the socket status is inetStatusConnected (not recommended), or by waiting for an inetSockStatusChangeEvent event from INetLibGetEvent and checking the status then (preferred).</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">Wireless Internet Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                    | inetErrSettingSizeInvalid                                                                                                                                            | bufLen is the incorrect<br>size for the specified<br>setting                         |
|                    |                                                                                                                                                                      |                                                                                      |
| <b>Comments</b>    | This call modifies attributes of an HTTP request formed by<br>INetLibSockHTTPReqCreate. Generally, attributes are set only<br>before calling INetLibSockHTTPReqSend. |                                                                                      |

## Internet Library

*INetLibSockHTTPReqCreate*

---

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockHTTPReqCreate\(\)](#),  
[INetLibSockHTTPReqSend\(\)](#)

### INetLibSockHTTPReqCreate Function

**Purpose** Forms an HTTP request for the socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockHTTPReqCreate (UInt16 libRefnum,  
MemHandle sockH, UInt8 *verbP,  
UInt8 *resNameP,  
UInt8 *referrerP)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *sockH*  
Handle (allocated by `INetLibSockOpen` or  
`INetLibURLOpen`) of the socket.
- *verbP*  
Reserved for future use.
- *resNameP*  
Pointer to a string holding the name of the resource to get or  
put.
- *referrerP*  
Pointer to a string holding the name of the referring URL, or  
NULL if none.

**Returns**

|                                   |                    |
|-----------------------------------|--------------------|
| 0                                 | No error           |
| <code>inetErrParamsInvalid</code> | Not an HTTP socket |

**Comments** This call forms an HTTP request for the socket. The request is not actually sent to the remote host until [INetLibSockHTTPReqSend\(\)](#) is called. The HTTP verb used in the request is determined by the value of the `writeP` parameter passed to `INetLibSockHTTPReqSend`: if this parameter is NULL, "GET" is used. Otherwise, "POST" is used.

After a call to `INetLibSockHTTPReqCreate` but before a call to `INetLibSockHTTPReqSend`, the application can add additional HTTP request headers using [`INetLibSockHTTPAttrSet\(\)`](#).

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**        [`INetLibSockHTTPAttrSet\(\)`](#), [`INetLibSockHTTPReqSend\(\)`](#)

## INetLibSockHTTPReqSend Function

**Purpose**        Sends an HTTP request to the remote host or looks for data in the cache.

**Declared In**   `INetMgr.h`

**Prototype**    `Err INetLibSockHTTPReqSend (UInt16 libRefnum,  
                                MemHandle sockH, void *writeP,  
                                UInt32 writeLen,  
                                Int32 timeout)`

**Parameters**      
→ *libRefnum*  
                  Refnum of the Internet library.  
  
→ *sockH*  
                  Handle (allocated by `INetLibSockOpen` or `INetLibURLOpen`) of the socket.  
  
→ *writeP*  
                  Pointer to additional data to send after the request headers.  
                  Usually used for POST and PUT operations.  
  
→ *writeLen*  
                  Number of bytes in *writeP*.  
  
→ *timeout*  
                  Timeout in ticks.

**Returns**

|                                        |                                        |
|----------------------------------------|----------------------------------------|
| <code>0</code>                         | No error                               |
| <code>inetErrRequestTooLong</code>     | Request too big                        |
| <code>inetErrEncryptionNotAvail</code> | Encryption requested but not available |

**Comments**    This call sends an HTTP request created by `INetLibSockHTTPReqCreate` and `INetLibSockHTTPAttrSet`

to the remote host. If this is an POST or PUT operation, the data to write can be specified in `writeP`.

`INetLibSockHTTPReqSend` doesn't always do network I/O. If the proper socket flag is set, it checks first to see if the requested data is already in the cache. If it is, then a pointer to the cached data is stored in the socket and the socket status is updated to show that data is ready to be read. This will trigger an [inetSockReadyEvent](#) event.

The socket flag (`inetOpenURLFlagLookInCache`) that causes the cache to be checked first can be set via the `flags` parameter to [INetLibURLOpen\(\)](#) or by calling [INetLibSockSettingSet\(\)](#) with the appropriate setting (`inetSockSettingFlags`).

After sending the request, the application can wait for the response to arrive by either polling `INetLibSockStatus` until the `inputReady` boolean is set (not recommended), or by waiting for an `inetSockReadyEvent` event from `INetLibGetEvent` (preferred).

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockHTTPReqCreate\(\)](#),  
[INetLibSockHTTPAttrSet\(\)](#), [INetLibGetEvent\(\)](#)

## INetLibSockOpen Function

**Purpose** Creates and returns a new inet socket handle.

**Declared In** `INetMgr.h`

**Prototype**

```
Err INetLibSockOpen (UInt16 libRefnum,  
                    MemHandle inetH, UInt16 scheme,  
                    MemHandle *sockHP)
```

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *inetH*  
Inet handle allocated by `INetLibOpen`.
- *scheme*  
The protocol scheme to use. Specify one of the [INetSchemeEnum](#) types.

← *sockHP*

Pointer to the address where the socket handle is returned.

**Returns**

|                                        |                                    |
|----------------------------------------|------------------------------------|
| 0                                      | No error                           |
| <code>inetErrTooManySockets</code>     | Too many sockets open              |
| <code>inetErrSchemeNotSupported</code> | Requested URL scheme not supported |

**Comments**

This call creates a new socket for the given scheme. No network I/O is performed. This is a relatively low level call that can be used in place of `INetLibURLOpen` when finer control over the socket settings is required.

Using `INetLibURLOpen`, an HTTP request can be handled with the simple sequence: `INetLibURLOpen`, `INetLibSockRead`, and `INetLibSockClose`. When using `INetLibSockOpen`, the same HTTP request would be handled by replacing the `INetLibURLOpen` call with the sequence: `INetLibSockOpen`, `INetLibSockSettingSet` (optional), `INetLibSockConnect`, `INetLibSockHTTPReqCreate`, `INetLibSockHTTPAttrSet` (optional), and `INetLibSockHTTPReqSend`.

The use of `INetLibSockOpen` allows an application finer control over the socket settings (by calling `INetLibSockSettingSet`) and the HTTP request headers (by calling `INetLibSockHTTPAttrSet`).

**Compatibility**

Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**

[`INetLibOpen\(\)`](#), [`INetLibURLOpen\(\)`](#), [`INetLibSockRead\(\)`](#), [`INetLibSockClose\(\)`](#), [`INetLibSockSettingSet\(\)`](#), [`INetLibSockHTTPAttrSet\(\)`](#)

Reads data from a socket.

**Declared In** `INetMgr.h`

[illegible]

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <ul style="list-style-type: none"><li>→ <i>libRefnum</i><br/>Refnum of the Internet library.</li><li>→ <i>sockH</i><br/>Inet handle allocated by <code>INetLibOpen</code>.</li><li>→ <i>bufP</i><br/>Pointer to buffer where the data is placed.</li><li>→ <i>reqBytes</i><br/>Requested number of bytes.</li><li>← <i>actBytesP</i><br/>Pointer to the actual number of bytes read.</li><li>→ <i>timeout</i><br/>Timeout in ticks. Specify <code>evtWaitForever</code> to wait forever.</li></ul> |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Returns

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

|                 |                                                                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b> | This call attempts to read <code>reqBytes</code> bytes from the given socket. It returns the actual number of bytes read in <code>*actBytesP</code> . If the connection with the remote host has been closed, <code>*actBytesP</code> contains 0 on exit. |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Note that it is normal for the actual bytes read to be less than the requested number of bytes. The application should be prepared to call this routine repeatedly until the desired number of bytes have been read or until `*actBytesP` contains 0, indicating the connection has been closed, or until an error is returned.

This call returns as much data as possible without blocking, however, if no data is available to be read, it does block until at least one byte is available.

Normally, applications will wait for an `inetSockReadyEvent` from `INetLibGetEvent()` before calling `INetLibSockRead`.

Alternatively, the application could call [INetLibSockStatus\(\)](#) to determine if the socket has any data ready (not recommended), or could simply rely on `INetLibSockRead` to block until at least one byte is available to read. If no data is available before the timeout expires, `inetErrReadTimeout` error is returned.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibURLOpen\(\)](#), [INetLibSockOpen\(\)](#),  
[INetLibSockStatus\(\)](#), [INetLibSockClose\(\)](#),  
[INetLibGetEvent\(\)](#)

## INetLibSockSettingGet Function

**Purpose** Retrieves a socket setting.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockSettingGet (UInt16 libRefnum,  
MemHandle socketH, UInt16 setting, void *bufP,  
UInt16 *bufLenP)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *socketH*  
Handle (allocated by `INetLibSockOpen` or  
`INetLibURLOpen`) of the socket to get a setting from.
- *setting*  
The setting to get. Specify one of the  
[INetSockSettingEnum](#) values.
- ← *bufP*  
Pointer to buffer where the setting value is to be placed.
- ↔ *bufLenP*  
Size of *bufP* on entry; size of returned value on exit.

**Returns**

0 No error

|                                        |                                                          |
|----------------------------------------|----------------------------------------------------------|
| <code>inetErrParamsInvalid</code>      | Invalid setting requested                                |
| <code>inetErrSettingSizeInvalid</code> | *bufLenP is the incorrect size for the requested setting |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockSettingSet\(\)](#)

## INetLibSockSettingSet Function

**Purpose** Changes a setting of a socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockSettingSet (UInt16 libRefnum,  
MemHandle socketH, UInt16 setting, void *bufP,  
UInt16 bufLen)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *socketH*  
Handle (allocated by `INetLibSockOpen` or `INetLibURLOpen`) of the socket to set.
- *setting*  
The setting to set. Specify one of the [INetSockSettingEnum](#) values.
- *bufP*  
Pointer to buffer containing the new setting value.
- *bufLen*  
Size of new setting in *bufP*.

**Returns**

|                                           |                                              |
|-------------------------------------------|----------------------------------------------|
| 0                                         | No error                                     |
| <code>inetErrSettingNotImplemented</code> | Invalid setting specified                    |
| <code>inetErrSettingSizeInvalid</code>    | bufLen is the incorrect size for the setting |

**Comments** This call can be use to override a general setting for a particular socket.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockSettingGet\(\)](#)

## INetLibSockStatus Function

**Purpose** Retrieves the current status of a socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockStatus (UInt16 libRefnum,  
MemHandle socketH, UInt16 *statusP,  
Err *sockErrP,  
Boolean *inputReadyP, Boolean *outputReadyP)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *socketH*  
Handle (allocated by `INetLibSockOpen` or `INetLibURLOpen`) of the socket to get status on.
- ← *statusP*  
Pointer to the address where the status is returned. The status will be one of the [INetStatusEnum](#) values.
- ← *sockErrP*  
Currently unused.
- ← *inputReadyP*  
Pointer to a Boolean; true is returned if the socket has data available to read.
- ← *outputReadyP*  
Pointer to a Boolean; true is returned if the socket can accept data for writing.

**Returns**

0 No error

**Comments** Most applications that use `INetLibGetEvent` will rarely need to use this call since socket status changes are returned in the event structure.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibURLOpen\(\)](#), [INetLibSockOpen\(\)](#),  
[INetLibSockRead\(\)](#), [INetLibGetEvent\(\)](#)

## INetLibURLCrack Function

**Purpose** Cracks a URL text string into its components.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibURLCrack (UInt16 libRefnum,  
                          UInt8 *urlTextP, INetURLType *urlP)`

**Parameters**

- $\rightarrow$  `libRefnum`  
Refnum of the Internet library.
- $\rightarrow$  `urlTextP`  
Pointer to URL text string.
- $\leftrightarrow$  `urlP`  
Pointer to address where the URL information block is to be returned.

### Returns

|                                       |                                                                         |
|---------------------------------------|-------------------------------------------------------------------------|
| 0                                     | No error                                                                |
| <code>inetErrParamsInvalid</code>     | <code>urlTextP</code> is NULL or empty, or<br><code>urlP</code> is NULL |
| <code>inetErrURLVersionInvalid</code> | <code>urlP</code> is wrong version                                      |

**Comments** If a pointer member of `urlP` is set to NULL on entry, then on exit it will point to the start of that component within the original `urlTextP` string; the associated member length is set to the length of that URL component. If a pointer member of `urlP` is not NULL on entry, then it must point to a buffer of sufficient size to hold the member data, and on exit the component string will be copied into this buffer and the associated member length will be updated with the actual size. Note that the returned strings are not null-terminated, so the length values are important.

It's easiest to initialize the `InetURLType` block to zeros and let this function fill in all the information about the URL components.

The InetURLType block returned from this function has the following structure:

---

```
typedef struct {
    UInt16 version; // 0, for future compatibility
    UInt8 *schemeP; // ptr to scheme portion
    UInt16 schemeLen; // size of scheme portion
    UInt16 schemeEnum; // INetSchemeEnum; the scheme
    UInt8 *usernameP; // ptr to username portion
    UInt16 usernameLen; // size of username
    UInt8 *passwordP; // ptr to password portion
    UInt16 passwordLen; // size of password
    UInt8 *hostnameP; // ptr to host name portion
    UInt16 hostnameLen; // size of host name
    UInt16 port; // port number
    UInt8 *pathP; // ptr to path portion
    UInt16 pathLen; // size of path
    UInt8 *paramP; // ptr to param (;param)
    UInt16 paramLen; // size of param
    UInt8 *queryP; // ptr to query (?query)
    UInt16 queryLen; // size of query
    UInt8 *fragP; // ptr to fragment (#frag)
    UInt16 fragLen; // size of fragment
} INetURLType
```

---

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibURLGetInfo Function

|                    |                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Returns information about a URL.                                                                                                                                                                                                    |
| <b>Declared In</b> | INetMgr.h                                                                                                                                                                                                                           |
| <b>Prototype</b>   | Err INetLibURLGetInfo (UInt16 libRefnum,<br>MemHandle inetH, UInt8 *urlTextP,<br>INetURLInfoType *urlInfoP)                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>               Refnum of the Internet library.</p> <p>→ <i>inetH</i><br/>               Inet handle allocated by INetLibOpen.</p> <p>→ <i>urlTextP</i><br/>               Pointer to URL text string.</p> |

## Internet Library

### *INetLibURLOpen*

---

↔ *urlInfoP*

Pointer to address where the URL information structure is to be returned.

#### Returns

0

No error

*inetErrParamsInvalid*

*urlInfoP* is NULL or incorrect version

#### Comments

The *InetURLInfo* block returned from this function has the following structure:

---

```
typedef struct {
    UInt16 version; // 0, for future compatibility
    UInt16 flags; // flags word
    UInt32 undefined; // reserved for future use
} INetURLInfo
```

---

The flags word can consist of some combination of these values:

---

```
inetURLInfoFlagIsSecure // URL was encrypted
inetURLInfoFlagIsRemote // URL was retrieved
from the net
inetURLInfoFlagIsInCache // URL is stored in
the cache
```

---

#### Compatibility

Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibURLOpen Function

#### Purpose

Accesses a URL on the Internet or in the cache.

#### Declared In

*INetMgr.h*

#### Prototype

```
Err INetLibURLOpen (UInt16 libRefnum,
    MemHandle inetH, UInt8 *urlP,
    UInt8 *cacheIndexURLP, MemHandle *sockHP,
    Int32 timeout, UInt16 flags)
```

#### Parameters

→ *libRefnum*

Refnum of the Internet library.

→ *inetH*

Inet handle allocated by *INetLibOpen*.

- *urlP*  
Pointer to string containing the URL to access.
- *cacheIndexURLP*  
Pointer to URL string under which the requested URL should be indexed in the cache. Specify NULL if you don't need to index the cache. If you are using the Web Clipping Application Viewer cache (not recommended), you must follow the Viewer convention, which is to pass the URL of the active PQA.
- ← *sockHP*  
Pointer to address where the socket handle is returned.
- *timeout*  
Timeout in ticks. Specify `evtWaitForever` to wait forever.
- *flags*  
Flags indicating caching and encryption options desired. Specify zero, one, or more of the URL open flags (see [URL Open Constants](#)).

#### Returns

- |                                   |                           |
|-----------------------------------|---------------------------|
| 0                                 | No error                  |
| <code>inetErrParamsInvalid</code> | <code>urlP</code> is NULL |

#### Comments

This call sets up a connection to a resource on the Internet addressed by `urlP` and returns a socket handle. Note that if you specify that the cache should be searched first, and if the data is found in the cache, no network I/O occurs. The application can then read that socket resource through the [INetLibSockRead\(\)](#) call.

This call is a convenience routine that internally makes the following calls for http URLs: `INetLibSockOpen`, `INetLibSockConnect`, `INetLibSockHTTPReqCreate`, and `INetLibSockHTTPReqSend`.

This routine returns immediately before performing any required network I/O. It is then up to the caller to either block on `INetLibSockRead`, or to use [INetLibGetEvent\(\)](#) to model asynchronous operation. Using `INetLibGetEvent` is the preferred way of performing network I/O since it maximizes battery life and user-interface responsiveness.

## Internet Library

### *INetLibURLsAdd*

---

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockOpen\(\)](#), [INetLibSockConnect\(\)](#),  
[INetLibSockRead\(\)](#), [INetLibSockClose\(\)](#)

## INetLibURLsAdd Function

**Purpose** Concatenates two URLs, resulting in one absolute URL.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibURLsAdd (UInt16 libRefnum,  
Char *baseURLStr, Char *embeddedURLStr,  
Char *resultURLStr, UInt16 *resultLenP)`

**Parameters**

- *libRefnum*  
Refnum of the Internet library.
- *baseURLStr*  
Pointer to base URL string.
- *embeddedURLStr*  
Pointer to URL text string to append.
- ↔ *resultURLStr*  
Pointer to resulting URL string.
- ↔ *resultLenP*  
Pointer to size of *resultURLStr* buffer on entry. On exit,  
pointer to resulting URL length (including null terminator).

**Returns**

0 No error

**Comments** Used to append a URL fragment to a base URL, resulting in an absolute URL string that can be passed to [INetLibURLOpen\(\)](#) or other functions. This routine ensures that the resulting string conforms to the URL format.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibWiCmd Function

**Purpose** Invokes a command that operates on the wireless indicator.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Prototype</b>   | <code>Boolean INetLibWiCmd (UInt16 refNum, UInt16 cmd,<br/>int enableOrX, int y)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>refNum</i><br/>Refnum of the Internet library.</p> <p>→ <i>cmd</i><br/>The command to invoke. Specify one of the <code>WiCmdEnum</code> values (see Comments section).</p> <p>→ <i>enableOrX</i><br/>If <i>cmd</i> is <code>wiCmdSetEnabled</code>, specify 1 to enable the wireless indicator or 0 to disable it. If <i>cmd</i> is <code>wiCmdSetLocation</code>, this specifies the x coordinate of the location.</p> <p>→ <i>y</i><br/>The y coordinate of the location. Used only if <i>cmd</i> is <code>wiCmdSetLocation</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Returns</b>     | If <i>cmd</i> is <code>wiCmdEnabled</code> , this function returns <code>true</code> if the wireless indicator is enabled or <code>false</code> if it is not. For other command types, the return value is undefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Comments</b>    | <p>The wireless indicator is a 19x13 pixel image on the screen to indicate the current wireless signal strength. This shows as 0 - 5 bars. If the application is in a non-modal window with a title bar, the preferred location for the indicator is at (140,1).</p> <p>It automatically updates itself as long as you are calling <code>INetLibGetEvent</code>. It should be shown on screen while a wireless transaction is in progress. It may also be shown when the user has nothing useful to do next but initiate a wireless transaction, and there isn't much other useful information being displayed.</p> <p>The <code>WiCmdEnum</code> enum specifies a command that operates on the wireless indicator in the user interface. The definition of this type is found in <code>WirelessIndicator.h</code> and is as follows:</p> <hr/> <pre>typedef enum {<br/>wiCmdInit =0,<br/>wiCmdClear,<br/>wiCmdSetEnabled,<br/>wiCmdDraw,<br/>wiCmdEnabled,<br/>wiCmdSetLocation,<br/>}</pre> |

#### Value Descriptions

|                  |                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wiCmdInit        | Initializes the wireless indicator. You must invoke this command first, before using any of the others.                                                                                     |
| wiCmdClear       | Applications shouldn't use this command. To erase the indicator, disable it by using <code>wiCmdSetEnabled</code> and passing 0 for <code>enableOrX</code> .                                |
| wiCmdSetEnabled  | Enables or disables the wireless indicator.                                                                                                                                                 |
| wiCmdDraw        | Redraws the wireless indicator using the latest data. Applications don't need to use this command since the indicator is redrawn automatically by <code>INetLibGetEvent</code> .            |
| wiCmdEnabled     | Returns a Boolean indicating if the wireless indicator is enabled.                                                                                                                          |
| wiCmdSetLocation | Sets the location for the wireless indicator on the screen.                                                                                                                                 |
| wiCmdErase       | Erases the wireless indicator. Applications shouldn't use this command. To erase the indicator, disable it by using <code>wiCmdSetEnabled</code> and passing 0 for <code>enableOrX</code> . |

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

# PalmOSGlue Library

---

This chapter describes the API provided in the link library PalmOSGlue (`PalmOSGlue.lib` or `libPalmOSGlue.a`).

You use PalmOSGlue if you want to use the international and text manager features described in the chapter “[Localized Applications](#)” on page 369 in the *Palm OS Programmer’s Companion*, vol. I and you want to maintain backward compatibility with earlier releases of Palm OS®. If you link with PalmOSGlue, include the headers in the folder `Incs\Libraries\PalmOSGlue`, and make calls as they are listed in this chapter, then your code will run regardless of whether the device’s version of the operating system implements international support. The code in PalmOSGlue either uses the text manager or international manager on the ROM or, if the managers don’t exist, executes a simple Latin equivalent of the function.

---

**NOTE:** PalmOSGlue is a link library, not a shared library. Linking with this library increases your application’s code size. The amount by which your code size increases varies depending on the number of library functions you call. Use PalmOSGlue only on versions 2.0 and later of Palm OS.

---

In addition to covering the text and international manager API, PalmOSGlue adds some functions that are not included in any version of the Palm OS. This chapter describes the functions that are unique to PalmOSGlue and provides a mapping of PalmOSGlue calls to calls that exist in later versions of Palm OS.

## PalmOSGlue Functions

The following table shows the mapping between the functions declared in the glue headers and the international functions and macros. To learn more about a glue function, click the link in the right column.

This table lists only those functions that map to a function that exists in newer versions of the OS. The functions that are exclusive to PalmOSGlue are not listed. They are described following this table.

**Table 75.1 PalmOSGlue function mappings**

| <b>This PalmOSGlue function...</b> | <b>...is identical to...</b>                 |

## **BmpGlueGetBits Function**

|                    |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Retrieve the bitmap's data. Unlike <a href="#">BmpGetBits()</a> , this function can be used with all versions of Palm OS. |
| <b>Declared In</b> | <code>BmpGlue.h</code>                                                                                                    |
| <b>Prototype</b>   | <code>void *BmpGlueGetBits (BitmapType *bitmapP)</code>                                                                   |
| <b>Parameters</b>  | <code>→ bitmapP</code><br>Pointer to the bitmap's structure (a <a href="#">BitmapType</a> ).                              |
| <b>Returns</b>     | Returns a pointer to the bitmap's data.                                                                                   |

## **BmpGlueGetCompressionType Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Returns the compression type used for a specified bitmap.                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>BmpGlue.h</code>                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <code>BitmapCompressionType BmpGlueGetCompressionType<br/>(const BitmapType *bitmapP)</code>                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <code>→ bitmapP</code><br>Pointer to the bitmap.                                                                                                                                                                                                                                                                                                                                          |
| <b>Returns</b>     | Returns a <a href="#">BitmapCompressionType</a> enum value. If the specified bitmap is not compressed, this function returns <code>BitmapCompressionTypeNone</code> . If the specified bitmap's encoding version is less than 2, this function returns <code>BitmapCompressionTypeScanLine</code> . If <code>bitmapP</code> is <code>NULL</code> , this function generates a fatal alert. |
| <b>See Also</b>    | <a href="#">BmpCompress()</a>                                                                                                                                                                                                                                                                                                                                                             |

## **BmpGlueGetTransparentValue Function**

- Purpose** Indicates if a specified bitmap has transparency—if, when the bitmap is drawn, pixels of a certain value won't be drawn.
- Declared In** `BmpGlue.h`
- Prototype** `Boolean BmpGlueGetTransparentValue  
(const BitmapType *bitmapP,  
UInt32 *transparentValueP)`
- Parameters**  $\rightarrow$  *bitmapP*  
Pointer to the bitmap.
- $\leftarrow$  *transparentValueP*  
The pixel value that isn't drawn, if the bitmap has transparency. If the value returned by `BmpGlueGetTransparentValue` is false, *\*transparentValueP* is left unchanged.
- Returns** Returns true if, when drawing the specified bitmap, Palm OS doesn't draw pixels that have a value equal to that returned in *transparentValueP*. Returns false if all pixels are drawn.
- Comments** You can specify the transparent color when you create the bitmap using Constructor.
- See Also** [`BmpGlueSetTransparentValue\(\)`](#)

## **BmpGlueSetTransparentValue Function**

- Purpose** Causes pixels of a specified color not to be drawn when the bitmap is drawn.
- Declared In** `BmpGlue.h`
- Prototype** `void BmpGlueSetTransparentValue  
(BitmapType *bitmapP, UInt32 transparentValue)`
- Parameters**  $\rightarrow$  *bitmapP*  
Pointer to the bitmap. Note that this must not be a resource bitmap: resource bitmaps cannot be changed.
- $\rightarrow$  *transparentValueP*  
The pixel value that isn't drawn.
- Returns** Returns nothing.

- Comments** Does nothing if `bitmapP` is `NULL`, if `bitmapP` is an off-screen bitmap, or if `transparentValue` is invalid given the bitmap's bit depth.
- If the specified bitmap's encoding version is less than 2, this function updates it to 2.
- See Also** [BmpGlueGetTransparentValue\(\)](#)

## CtlGlueGetControlStyle Function

- Purpose** Return the type of the control, such as button, slider, and so on.
- Declared In** `CtlGlue.h`
- Prototype** `ControlStyleType CtlGlueGetControlStyle  
(const ControlType *ctlP)`
- Parameters**  $\rightarrow$  `ctlP`  
A pointer to a [ControlType](#) structure.
- Returns** Returns one of the [ControlStyleType](#) constants.
- Compatibility** Implemented only in the PalmOSGlue library.

## CtlGlueGetFont Function

- Purpose** Gets the font used when drawing a specified control's label.
- Declared In** `CtlGlue.h`
- Prototype** `FontID CtlGlueGetFont (const ControlType *ctlP)`
- Parameters**  $\rightarrow$  `ctlP`  
Pointer to the control object.
- Returns** Returns the ID of the font used to draw the control's label.
- See Also** [CtlGlueSetFont\(\)](#)

## **CtlGlueGetGraphics Function**

|                      |                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Gets the bitmaps displayed in place of a specified control's label.                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | <code>CtlGlue.h</code>                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <code>void CtlGlueGetGraphics (const ControlType *ctlP,<br/>DmResID *bitmapID, DmResID *selectedBitmapID)</code>                                                                                                                                                                                                                                          |
| <b>Parameters</b>    | <p>→ <i>ctlP</i><br/>Pointer to the control.</p> <p>← <i>bitmapID</i><br/>Resource ID of the bitmap to display when the graphical control is not selected.</p> <p>← <i>selectedBitmapID</i><br/>Resource ID of the bitmap to display when the graphical control is selected, if, when selected, the graphical control should show a different bitmap.</p> |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>      | <p>If the specified control is not a graphical control—one that displays a bitmap in place of the text label—*<i>bitmapID</i> and *<i>selectedBitmapID</i> are set to zero.</p> <p>This function works with any graphical control, including sliders.</p>                                                                                                 |
| <b>Compatibility</b> | Implemented only if 3.5 New Feature Set is present.                                                                                                                                                                                                                                                                                                       |
| <b>See Also</b>      | <a href="#">CtlGlueSetFont()</a> , <a href="#">CtlSetGraphics</a>                                                                                                                                                                                                                                                                                         |

## **CtlGlueIsGraphical Function**

|                    |                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return whether or not a control is a graphical control.                                                                                                                  |
| <b>Declared In</b> | <code>CtlGlue.h</code>                                                                                                                                                   |
| <b>Prototype</b>   | <code>Boolean CtlGlueIsGraphical<br/>(ControlType *controlP)</code>                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>controlP</i><br/>Pointer to the control</p>                                                                                                                      |
| <b>Returns</b>     | Returns <code>true</code> if the control indicated by <i>controlP</i> is a graphical control, a slider, or a feedback slider. Otherwise, it returns <code>false</code> . |

## CtlGlueNewSliderControl Function

- Purpose** Create a new slider or feedback slider dynamically and install it in the specified form. The newly-created control is marked as a graphical control.
- Declared In** CtlGlue.h
- Prototype**

```
SliderControlType *CtlGlueNewSliderControl
(void **formPP, UInt16 ID,
ControlStyleType style,
DmResID thumbID, DmResID backgroundID,
Coord x,
Coord y, Coord width, Coord height,
UInt16 minValue, UInt16 maxValue,
UInt16 pageSize,
UInt16 value)
```
- Parameters**
- ↔ *formPP*  
Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the formPP value may change if the object moves in memory. In subsequent calls, always use the new formPP value returned by this function.
  - *ID*  
Symbolic ID of the slider.
  - *style*  
Either sliderCtl or feedbackSliderCtl. See ControlStyleType.
  - *thumbID*  
Resource ID of the bitmap to display as the slider thumb. The slider thumb is the knob that the user can drag to change the slider's value. To use the default thumb bitmap, pass NULL for this parameter.
  - *backgroundID*  
Resource ID of the bitmap to display as the slider background. To use the default background bitmap, pass NULL for this parameter.
  - *x*  
Horizontal coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.

- *y*  
Vertical coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.
- *width*  
Width of the slider, expressed in pixels. Valid values are 1–160.
- *height*  
Height of the slider, expressed in pixels. Valid values are 1–160.
- *minValue*  
Value of the slider when its thumb is all the way to the left.
- *maxValue*  
Value of the slider when its thumb is all the way to the right.
- *pageSize*  
Amount by which to increase or decrease the slider's value when the user clicks to the right or left of the thumb.
- *value*  
The initial value to display in the slider.

**Returns** Returns a pointer to the new slider control. See *SliderControlType*.

**Compatibility** Implemented only if 3.5 New Feature Set is present.

**See Also** *CtlNewSliderControl*, *CtlNewGraphicControl*, *CtlNewControl*, *CtlValidatePointer*, *FrmRemoveObject*

## **CtlGlueSetFont Function**

**Purpose** Sets the font to use when drawing the control's label.

**Declared In** *CtlGlue.h*

**Prototype** `void CtlGlueSetFont (ControlType *ctlP,  
FontID fontID)`

**Parameters**

- *ctlP*  
Pointer to the control object.
- *fontID*  
The ID of the font to use when drawing the control's label.

**Returns** Returns nothing.

**See Also** [CtlGlueGetFont\(\)](#)

## **CtlGlueSetFrameStyle Function**

**Purpose** Set the frame style for a button control.

**Declared In** CtlGlue.h

**Prototype** `void CtlGlueSetFrameStyle (ControlType *controlP,  
ButtonFrameType frameStyle)`

**Parameters**   
→ *controlP*  
Pointer to a button control.  
  
→ *frameStyle*  
Frame style to be applied to the button. Supply one of these values (declared in the [ButtonFrameType](#) enum):  
noButtonFrame, standardButtonFrame, or  
boldButtonFrame. Don't use rectangleButtonFrame;  
rectangular button frames have been deprecated.

**Returns** Returns nothing.

## **CtlGlueSetLeftAnchor Function**

**Purpose** Causes a control's left bound to be fixed or to float.

**Declared In** CtlGlue.h

**Prototype** `void CtlGlueSetLeftAnchor (ControlType *ctlP,  
Boolean leftAnchor)`

**Parameters**   
→ *ctlP*  
Pointer to the control.  
  
→ *leftAnchor*  
A value of true causes the left bound of the control to be fixed.

**Returns** Returns nothing.

**Comments** Used by controls that expand and shrink their width when the label is changed.

## **FldGlueGetLineInfo Function**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Retrieve the word-wrapping information for a visible line within a field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b>   | <code>FldGlue.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>     | <pre>Boolean FldGlueGetLineInfo     (const FieldType *fldP,      UInt16 lineNum, UInt16 *startP,      UInt16 *lengthP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | <p>→ <i>fldP</i><br/>A pointer to a <a href="#">FieldType</a> structure.</p> <p>→ <i>lineNum</i><br/>The number of the visible line in the field about which you want to retrieve information. Lines are numbered starting at 0.</p> <p>← <i>startP</i><br/>The byte offset into the <a href="#">FieldType</a>'s text field of the first character displayed by this line. If the line is blank, *startP is equal to the length of the field's text string.</p> <p>← <i>lengthP</i><br/>The length in bytes of the portion of the string displayed on this line. If the line is blank, the length is 0.</p> |
| <b>Returns</b>       | Returns <code>true</code> if <i>startP</i> and <i>endP</i> contain valid values, or <code>false</code> if the field is a single-line field or does not contain a line numbered <i>lineNum</i> .                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## **FntGlueGetDefaultFontID Function**

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the font ID of a default font.                                                                                                                      |
| <b>Declared In</b> | <code>FntGlue.h</code>                                                                                                                                     |
| <b>Prototype</b>   | <pre>FontID FntGlueGetDefaultFontID (     FontDefaultType inFontType)</pre>                                                                                |
| <b>Parameters</b>  | <p>→ <i>inFontType</i><br/>A <code>FontDefaultType</code> constant specifying one of the system default fonts. This value can be one of the following:</p> |

`defaultSystemFont`  
The default font for the system.

`defaultLargeFont`  
The default large font.

`defaultSmallFont`  
The default small font.

`defaultBoldFont`  
The default bold font.

**Returns** Returns the ID of `inFontType`.

**Comments** Use this function whenever you need to obtain a font ID for one of the system default fonts. The default fonts (and thus, the IDs for the default fonts) vary depending on the system's locale. For example, Japanese systems have a different set of default fonts than systems using the Latin character encoding.

Use this function in place of the constants that specify the IDs of default fonts, as shown in the following table.

| In place of this...        | ...use <code>FntGlueGetDefaultFontID</code> with this constant...                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>stdFont</code>       | <code>defaultSystemFont</code> (best for displaying text) or:<br><code>defaultSmallFont</code> (if you want a smaller font) |
| <code>largeFont</code>     | <code>defaultLargeFont</code>                                                                                               |
| <code>largeBoldFont</code> | <code>defaultLargeFont</code>                                                                                               |
| <code>boldFont</code>      | <code>defaultBoldFont</code>                                                                                                |

Note that `defaultSystemFont` and `defaultSmallFont` might return the same font ID or different font IDs, depending on the system locale.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [`FontSelect\(\)`](#), [`FntGetFont\(\)`](#), [`FntSetFont\(\)`](#)

## **FrmGlueGetActiveField Function**

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the active field for a form.                                                      |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                   |
| <b>Prototype</b>   | <pre>extern FieldType *FrmGlueGetActiveField<br/>    (const FormType *formP)</pre>       |
| <b>Parameters</b>  | $\rightarrow$ <i>formP</i><br>Pointer to the form, or NULL to use the active form.       |
| <b>Returns</b>     | Returns a pointer to the active field. Returns NULL if there is no active form or field. |

## **FrmGlueGetDefaultButtonID Function**

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Purpose</b>     | Gets the resource ID of the object on the form defined as the default button. |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                        |
| <b>Prototype</b>   | <pre>UInt16 FrmGlueGetDefaultButtonID<br/>    (const FormType *formP)</pre>   |
| <b>Parameters</b>  | $\rightarrow$ <i>formP</i><br>Pointer to the form.                            |
| <b>Returns</b>     | Returns the resource ID of the object defined as the default button.          |
| <b>See Also</b>    | <code>FrmDoDialog</code> , <a href="#"><u>FrmGlueSetDefaultButtonID()</u></a> |

## **FrmGlueGetHelpID Function**

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Gets the resource ID number of the form's help resource.                                                          |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                                            |
| <b>Prototype</b>   | <pre>UInt16 FrmGlueGetHelpID (const FormType *formP)</pre>                                                        |
| <b>Parameters</b>  | $\rightarrow$ <i>formP</i><br>Pointer to the form.                                                                |
| <b>Returns</b>     | Returns the resource ID number of the form's help resource. The help resource is a String resource (type 'tSTR'). |
| <b>See Also</b>    | <a href="#"><u>FrmGlueSetHelpID()</u></a>                                                                         |

## FrmGlueGetLabelFont Function

|                    |                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Gets the font used for a particular label that appears on a form.                                                                                                                                                                                              |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>FontID FrmGlueGetLabelFont<br/>    (const FormType *formP,<br/>     UInt16 labelID)</pre>                                                                                                                                                                 |
| <b>Parameters</b>  | <p>→ <i>formP</i><br/>Pointer to the form.</p> <p>→ <i>labelID</i><br/>ID of a label object in the form (the object's type must be <code>frmLabelObj</code>).</p>                                                                                              |
| <b>Returns</b>     | Returns a <code>FontID</code> value of 0 if either <code>labelID</code> is invalid or if the object indicated by <code>labelID</code> has a type other than <code>frmLabelObj</code> . Otherwise, this function returns the ID of the font used for the label. |
| <b>See Also</b>    | <code>FrmGetObjectType</code> , <a href="#"><u>FrmGlueSetLabelFont()</u></a>                                                                                                                                                                                   |

## FrmGlueGetMenuBarID Function

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Gets the ID number of the form's menu bar.                                                 |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                     |
| <b>Prototype</b>   | <pre>UInt16 FrmGlueGetMenuBarID<br/>    (const FormType *formP)</pre>                      |
| <b>Parameters</b>  | → <i>formP</i><br>Pointer to the form.                                                     |
| <b>Returns</b>     | Returns the ID number of the form's menu bar, or zero if the form doesn't have a menu bar. |
| <b>See Also</b>    | <code>FrmSetMenu</code>                                                                    |

## **FrmGlueGetObjIDFromObjPtr Function**

- Purpose** Return the ID of a form object given only a pointer to the form object and an indication of the object's type—a pointer to the form isn't required.
- Declared In** `FrmGlue.h`
- Prototype** `UInt16 FrmGlueGetObjIDFromObjPtr (void *formObjP,  
FormObjectKind objKind)`
- Parameters**   
→ *formObjP*  
Pointer to a user interface object appearing on a form.  
→ *objKind*  
The form object's type. Supply one of the values declared in the [FormObjectKind](#) enum.
- Returns** Returns the form object's ID, or `frmInvalidObjectID` if `objKind` is not a valid form object type.
- See Also** [FrmGetObjectID\(\)](#), [FrmGetObjectPtr\(\)](#), [FrmGetObjectType\(\)](#)

## **FrmGlueGetObjectUsable Function**

- Purpose** Returns whether an object in a form has been hidden.
- Declared In** `FrmGlue.h`
- Prototype** `Boolean  
FrmGlueGetObjectUsable (const FormType *formP,  
UInt16 objIndex)`
- Parameters**   
→ *formP*  
A pointer to a [FormType](#) structure.  
→ *objIndex*  
The index of the object on the form.
- Returns** Returns `true` if the object is usable, meaning that it is considered part of the user interface. Returns `false` if the object is not usable. Objects that are not usable never appear on the screen. The function [FrmHideObject\(\)](#) clears an object's usable bit to hide that the object.
- Comments** Implemented only in the PalmOSGlue library.

## FrmGlueSetDefaultButtonID Function

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Designates the object on the form that is to act as the default button.                                                                                                                                                                  |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <code>void FrmGlueSetDefaultButtonID (FormType *formP,<br/>                                  UInt16 defaultButton)</code>                                                                                                                |
| <b>Parameters</b>  | <div><div><math>\rightarrow</math> <i>formP</i></div><div>Pointer to the form.</div><div><math>\rightarrow</math> <i>defaultButton</i></div><div>The resource ID of the object on the form that is to be the default button.</div></div> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                         |
| <b>See Also</b>    | <code>FrmDoDialog</code> , <a href="#"><code>FrmGlueGetDefaultButtonID()</code></a>                                                                                                                                                      |

## FrmGlueSetHelpID Function

|                    |                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Designates the String resource that is to act as the form's help resource.                                                                                                                                                              |
| <b>Declared In</b> | <code>FrmGlue.h</code>                                                                                                                                                                                                                  |
| <b>Prototype</b>   | <code>void FrmGlueSetHelpID (FormType *formP,<br/>                          UInt16 helpRscID)</code>                                                                                                                                    |
| <b>Parameters</b>  | <div><div><math>\rightarrow</math> <i>formP</i></div><div>Pointer to the form.</div><div><math>\rightarrow</math> <i>helpRscID</i></div><div>The resource ID of the String resource that is to be the form's help resource.</div></div> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                        |
| <b>See Also</b>    | <a href="#"><code>FrmGlueGetHelpID()</code></a>                                                                                                                                                                                         |

## **FrmGlueSetLabelFont Function**

- Purpose** Sets the font used for a particular label that appears on a form.
- Declared In** `FrmGlue.h`
- Prototype** `void FrmGlueSetLabelFont (FormType *formP,  
                                UInt16 labelID, FontID fontID)`
- Parameters**
- *formP*  
Pointer to the form.
  - *labelID*  
ID of a label object in the form (the object's type must be `frmLabelObj`).
  - *fontID*  
ID of the font to be used for the label.
- Returns** Returns nothing.
- Comments** This function does nothing if either `labelID` is invalid or if the object indicated by `labelID` has a type other than `frmLabelObj`.
- See Also** `FrmGetObjectType`, [`FrmGlueGetLabelFont\(\)`](#)

## **IntlGlueGetRoutineAddress Function**

- Purpose** Return the address of a Text Manager function or of its PalmOSGlue equivalent.
- Declared In** `IntlGlue.h`
- Prototype** `void *IntlGlueGetRoutineAddress  
                                (IntlSelector selector,  
                                const void *latinSymbol)`
- Parameters**
- *selector*  
One of the routine selectors defined in `IntlMgr.h`.
  - *latinSymbol*  
The corresponding `TxtLatinfunc` symbol defined in `IntlGlue.h`.
- Returns** Returns the address of the native Palm OS function if it is defined. If the function is not defined, it returns the address of the corresponding PalmOSGlue function.

**Comments** Use IntlGlueGetRoutineAddress for performance reasons. You can use the address that it returns to call the function at that address without having to go through the International Manager's trap dispatch table. IntlGlueGetRoutineAddress is mostly useful for optimizing the performance of Text Manager functions that are called in a tight loop.

To call IntlGlueGetRoutineAddress, you must pass both the international trap for the function and the corresponding symbol. For example, to obtain the address of the TxtGetNextChar function or of its PalmOSGlue equivalent, you would make this call:

---

```
myTxtGetNextChar =  
    IntlGlueGetRoutineAddress(intlTxtGetNextChar,  
        TxtLatinGetNextChar);
```

---

The returned address is only valid while your application stays locked in memory. For this reason, you should only use the returned address up to the point where your application terminates. When the application starts up again, you should call IntlGlueGetRoutineAddress again.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [IntlGetRoutineAddress\(\)](#)

## **LmGlueGetSystemLocale Function**

**Purpose** Return the system locale and system character encoding.

**Declared In** LmGlue.h

**Prototype** `CharEncodingType LmGlueGetSystemLocale  
(LmLocaleType *oSystemLocale)`

**Parameters**  $\leftarrow$  *oSystemLocale*  
Points to an [LmLocaleType](#) struct that identifies the system locale.

**Returns** Returns the system character encoding, unless *oSystemLocale* is null. For details on CharEncodingType, see "[Character Encoding Constants](#)" on page 737.

**Compatibility** Implemented only if [5.3SC New Feature Set](#) is present.

**See Also** [OmGetSystemLocale\(\)](#)

## LstGlueGetDrawFunction Function

**Purpose** Return a pointer to a list's drawing callback function.

**Declared In** `LstGlue.h`

**Prototype** `void *LstGlueGetDrawFunction (ListType *listP)`

**Parameters** `→ listP`  
Pointer to a list object.

**Returns** Returns a pointer to the callback function that draws the list's items. If a callback function hasn't been set for the specified list, this function returns NULL.

**See Also** [LstSetDrawFunction\(\)](#)

## LstGlueGetFont Function

**Purpose** Get the font used to draw a list's text strings.

**Declared In** `LstGlue.h`

**Prototype** `FontID LstGlueGetFont (const ListType *listP)`

**Parameters** `→ listP`  
Pointer to the list.

**Returns** Returns the ID of the font used to draw all list text strings.

**See Also** [LstGlueSetFont\(\)](#)

## LstGlueGetItemsText Function

**Purpose** Get the text strings that represent the items in a list.

**Declared In** `LstGlue.h`

**Prototype** `Char **LstGlueGetItemsText (const ListType *listP)`

**Parameters** `→ listP`  
Pointer to the list.

**Returns** Returns a pointer to an array of pointers to the text of the list choices.

**See Also** [LstGetSelectionText\(\)](#), [LstSetListChoices\(\)](#)

## **LstGlueSetFont Function**

**Purpose** Specify the font to be used to draw a list's text strings.

**Declared In** `LstGlue.h`

**Prototype** `void LstGlueSetFont (ListType *listP,  
FontID fontID)`

**Parameters** `→ listP`  
Pointer to the list.  
`→ fontID`  
ID of the font to be used to draw all list text strings.

**Returns** Returns nothing.

**See Also** [LstGlueGetFont\(\)](#)

## **LstGlueSetIncrementalSearch Function**

**Purpose** Enables or disables incremental search for a sorted popup list.

**Declared In** `LstGlue.h`

**Prototype** `void LstGlueSetIncrementalSearch (ListType *listP,  
Boolean incrementalSearch)`

**Parameters** `→ listP`  
Pointer to the list.  
`→ incrementalSearch`  
Set to true to enable incremental search, false to disable it.

**Returns** Returns nothing.

**Comments** If incremental search is enabled, when the list is displayed the user can navigate the list by entering up to five characters. The list will scroll to present the first list item that matches the entered characters. This feature only works for popup lists, and only works if the list is sorted and the list items are available to the List Manager (that is, you don't pass NULL to `LstSetListChoices`).

## MemGluePtrNew Function

- Purpose** Allocate a new nonmovable chunk in the dynamic heap. Unlike [MemPtrNew\(\)](#), this function lets you request chunks larger than 64KB.
- Declared In** `MemGlue.h`
- Prototype** `MemPtr MemGluePtrNew (UInt32 size)`
- Parameters**  $\rightarrow$  *size*  
The desired size of the chunk.
- Returns** Returns a pointer to the new chunk, or NULL if unsuccessful.
- Comments** On versions of Palm OS prior to 3.5, this function acts exactly like [MemPtrNew\(\)](#) and won't allocate chunks larger than 64K.

## SysGlueTrapExists Macro

- Purpose** Indicates if a given trap exists on the current system.
- Declared In** `SysGlue.h`
- Prototype** `#define SysGlueTrapExists (trapNum)`
- Parameters**  $\rightarrow$  *trapNum*  
One of the system trap constants.
- Returns** Returns true if the current operating system defines the system trap *trapNum*, or false if the trap does not exist on that version of the operating system.
- Compatibility** Implemented only in the PalmOSGlue library.

## TblGlueGetColumnMasked Function

- Purpose** Determines whether a particular table column is masked.
- Declared In** `TblGlue.h`
- Prototype** `Boolean TblGlueGetColumnMasked  
(const TableType *tableP, Int16 column)`
- Parameters**  $\rightarrow$  *tableP*  
Pointer to the table.

→ *column*

Column number (zero-based).

**Returns** Returns `true` if the column is masked, `false` otherwise.

**Comments** If a table cell's column is masked and the cell's row is also masked, the table cell is drawn on the screen but is shaded to obscure the information that it contains.

**See Also** [TblSetColumnMasked\(\)](#)

## **TblGlueGetItemPtr Function**

**Purpose** Return the pointer value stored in a table item. Unlike [TblGetItemPtr\(\)](#), this function can be used with all versions of Palm OS.

**Declared In** `TblGlue.h`

**Prototype** `void *TblGlueGetItemPtr (const TableType *tableP,  
                          Int16 row, Int16 column)`

**Parameters** → *tableP*  
Pointer to a table object.

→ *row*  
Row number of the item (zero-based).

→ *column*  
Column number of the item (zero-based).

**Returns** Returns the item's pointer value or `NULL` if the item does not have a pointer value.

**Comments** Certain types of table items display the value pointed to by the `ptr` field, while other types display the value stored in the `intValue` field (see the [TableItemType](#) description for details). An application may set the value of the `ptr` field even for items that use the `intValue` field. This function always returns the value of the `ptr` field.

**See Also** [TblSetItemPtr\(\)](#)

## **TxtGlueConvertEncoding Function**

- Purpose** Convert a text buffer from one character encoding to another. Unlike [TxtConvertEncoding\(\)](#), this function will operate on many handhelds running Palm OS 3.5.
- Declared In** `TxtGlue.h`
- Prototype** `Err TxtGlueConvertEncoding (Boolean newConversion, TxtConvertStateType *ioStateP, const Char *srcTextP, UInt16 *ioSrcBytes, CharEncodingType srcEncoding, Char *dstTextP, UInt16 *ioDstBytes, CharEncodingType dstEncoding, const Char *substitutionStr, UInt16 substitutionLen)`
- Parameters**
- *newConversion*  
Set to true if this function call is starting a new conversion, or false if this function call is a continuation of a previous conversion.
  - ↔ *ioStateP*  
If *newConversion* is false, this parameter must point to a [TxtConvertStateType](#) structure containing the same data used for the previous invocation. If *newConversion* is true and no subsequent calls are planned, this parameter can be NULL.
  - *srcTextP*  
Pointer to the source text buffer. If *newConversion* is true, this must point to the start of a text buffer. If *newConversion* is false, it may point to a location in the middle of a text buffer. In either case, it must point to an inter-character boundary.
  - ↔ *ioSrcBytes*  
A pointer to the length, in bytes, of the text starting at *srcTextP* that needs to be converted. Upon return, *\*ioSrcBytes* contains the number of bytes successfully processed.
  - *srcEncoding*  
The character encoding that the source text uses. This should be one of the [Character Encoding Constants](#).

→ *dstTextP*

Pointer to the destination text buffer, or NULL if you only want to know how large the destination text buffer must be (the minimum size is returned in *\*ioDstBytes*). If not NULL, *dstTextP* should point to a location where *TxtGlueConvertEncoding* can begin writing.

→ *ioDstBytes*

A pointer to the length, in bytes, of *dstTextP*. Upon return, *\*ioDstBytes* contains the number of bytes required to represent the source text in the new encoding.

→ *dstEncoding*

The character encoding to which to convert *srcTextP*. This should be one of the constants documented in “[Character Encoding Constants](#)” on page 737. Note that the encoding can be modified, giving you greater control over the conversion process: see “[Character Encoding Constant Modifiers](#)” on page 961.

→ *substitutionStr*

A string to be substituted for any invalid or unconvertible characters that occur in the source text. This string must already be in the destination encoding. If NULL, *TxtGlueConvertEncoding* immediately returns if it encounters an invalid character.

→ *substitutionLen*

The number of bytes in *substitutionStr*, not including the terminating null byte.

**Returns** Returns *errNone* upon success, or one of the following if an error occurs:

*txtErrConvertOverflow*

The destination buffer is not large enough to contain the converted text.

*txtErrConvertUnderflow*

The end of the source buffer contains a partial character.

*txtErrMalformedText*

An error in the source text encoding has been discovered.

`txtErrNoCharMapping`

The device does not contain a mapping between the source and destination encodings for at least one of the characters in `srcTextP`, and there is no substitution string.

`txtErrUnknownEncoding`

One of the specified encodings is unknown or can't be handled, or the function is being called on a handheld running a version of Palm OS prior to 3.5.

`txtErrUnknownEncodingFallbackCopy`

Either the source or destination encoding is unknown, and the best fit flag was set in the destination encoding. Before returning this error code, `TxtConvertEncoding` copies anything that is 7-bit ASCII from the source text buffer to the destination text buffer.

**Comments** This function converts `ioSrcBytes` of text in `srcTextP` from the `srcEncoding` to the `dstEncoding` character encoding and returns the result in `dstTextP`.

`TxtGlueConvertEncoding` can convert between the following “built-in” encodings and the device encoding:

- UTF-8
- UTF-16, UTF-16BE, UTF-16LE, UCS-2
- UTF-32, UTF-32BE, UTF-32LE, UCS-4<sup>1</sup>

It can also support a variety of encodings that are locale dependent. The only locale for which `TxtGlueConvertEncoding` supports additional encodings is simplified Chinese in those versions of Palm OS that support simplified Chinese. The additional source encodings supported for the simplified Chinese locale are:

- GB2312
- GBK
- ISO2022-CN
- Big5
- Big5+HKSCS

---

1. UTF-32, UTF-32BE, UTF-32LE, and UCS-4 are only built into handhelds running a version of Palm OS that supports simplified Chinese.

- CP1252
- ISO8859-1
- US ASCII (ISO646)
- GSM

The additional destination encodings supported for the simplified Chinese locale are:

- ISO2022-CN
- GSM

If the `charEncodingDstBestFitFlag` is supported (see “[Character Encoding Constant Modifiers](#)” on page 961) but is *not* set in the destination encoding passed to the function, and you specify an unsupported character encoding for either the source or the destination buffer, `TxtGlueConvertEncoding` returns `txtErrUnknownEncoding`.

You can retrieve the device’s encoding using the following function:

---

```
FtrGet(sysFtrCreator, sysFtrNumEncoding,  
      &encoding)
```

---

If you’re converting text that was received from the Internet, the encoding’s name is passed along with the text data. Use the [TxtNameToEncoding\(\)](#) function to convert the name to a [CharEncodingType](#) value.

The `dstTextP` buffer must be large enough to hold the result of converting `srcTextP` to the specified encoding. You can pass `NULL` for the `dstTextP` parameter to determine the required length of the buffer before actually doing the conversion.; the required length is returned in `ioDstBytes`.

If the function encounters an inconvertible character in the source text, it puts `substitutionStr` in the destination buffer in that character’s place and continues the conversion. When the conversion is complete, it returns `txtErrNoCharMapping` to indicate that an error occurred (assuming that no other higher-priority error occurred during the conversion). If `substitutionStr` is `NULL`, the function stops the conversion and immediately returns `txtErrNoCharMapping`. `ioSrcBytes` is set to the offset of the inconvertible character, `dstTextP` contains the

converted string up to that point, and `ioDstBytes` contains the size of the converted text. You can examine the character at `ioSrcBytes` and choose to move past it and continue the conversion. Follow the rules for making repeated calls to `TxtGlueConvertEncoding` as described in the next paragraph.

You can make repeated calls to `TxtGlueConvertEncoding` in a loop if you only want to convert part of the input buffer at a time. When you make repeated calls to this function, the first call should use `true` for `newConversion`, and `srcTextP` should point to the start of the text buffer. All subsequent calls should use the following values:

`newConversion`  
false.

`ioStateP`  
The same data that was returned by the previous invocation.

`srcTextP`  
The location where this call should begin converting. Typically, this would be the previous `srcTextP` plus the number of bytes returned in `ioSrcBytes`.

If you are skipping over an unconvertible character, `srcTextP` must point to the character after that location.

`ioSrcBytes`  
The number of bytes that this function call should convert.

`dstTextP`  
A pointer to a location where this function can begin writing the converted string. You might choose to have each function call write to a different destination buffer. To have successive calls write to the same buffer, pass the previous `dstTextP` plus the number of bytes returned in `ioDstBytes` each time.

`ioDstBytes`  
The number of bytes available for output in the `dstTextP` buffer. In other words, the number of bytes remaining.

**Compatibility** This function works only on Palm OS 3.5 and later.

In versions of Palm OS that do not support simplified Chinese, the focus of `TxtGlueConvertEncoding` is to convert between Unicode-encoded text and the device's character encoding. For this reason, `TxtGlueConvertEncoding` can only handle conversions

between the device's encoding and one of UTF-8, UCS-2, UTF-16LE, or UTF-16BE. If you specify any other character encoding for either the source or the destination buffer, the error code `txtErrUnknownEncoding` is returned.

## **TxtGlueCharIsVirtual Function**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return whether a character is a virtual character or not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b>   | <code>TxtGlue.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Parameters</b>    | <p>→ <i>inModifiers</i><br/>The value passed in the <code>modifiers</code> field of the <a href="#">keyDownEvent</a>.</p> <p>→ <i>inChar</i><br/>A character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Returns</b>       | Returns <code>true</code> if the character <code>inChar</code> is a virtual character, <code>false</code> otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>      | <p>Virtual characters are nondisplayable characters that trigger special events in the operating system, such as displaying low battery warnings or displaying the keyboard dialog. Virtual characters should never occur in any data and should never appear on the screen.</p> <p>Starting in Palm OS 3.1, the command modifier bit is always set in the <code>keyDownEvent</code> for a virtual character because the range for virtual characters overlaps the range for “real” characters that should appear on the screen. Earlier releases of the operating system did not always set the command modifier for virtual characters.</p> <p>You can use this function to test whether a character is virtual or not. Pass the <code>chr</code> and <code>modifiers</code> fields exactly as you received them in the <a href="#">keyDownEvent</a>, and this function performs the appropriate check based on the operating system version.</p> |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## **TxtGlueFindString Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Perform a case-insensitive search for a string in another string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | <pre>Boolean TxtGlueFindString     (const Char *inSourceStr,      const Char *inTargetStr,      UInt32 *outPos, UInt16 *outLength)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>inSourceStr</i><br/>Pointer to the string to be searched.</p> <p>→ <i>inTargetStr</i><br/>Prepared version of the string to be found. This string should either be passed directly from the <code>strToFind</code> field in the <a href="#">sysAppLaunchCmdFind</a> launch code's parameter block or it should be prepared using <a href="#">TxtGluePrepFindString()</a>.</p> <p>← <i>outPos</i><br/>Pointer to the offset of the match in <i>inSourceStr</i>.</p> <p>← <i>outLength</i><br/>Pointer to the length in bytes of the matching text.</p>                                                                                                                                                                                                                                                                                      |
| <b>Returns</b>     | <p>Returns <code>true</code> if the function finds <i>inTargetStr</i> within <i>inSourceStr</i>; <code>false</code> otherwise.</p> <p>If found, the values pointed to by the <i>outPos</i> and <i>outLength</i> parameters are set to the starting offset and the length of the matching text. Unlike <a href="#">TxtFindString()</a>, if the target string is not found, the values pointed to by <i>outPos</i> and <i>outLength</i> are not necessarily set to 0.</p> <p>The search that <code>TxtGlueFindString</code> performs is locale-dependent. On most ROMs with Latin-based encodings, <code>TxtGlueFindString</code> returns <code>true</code> only if the string is at the beginning of a word. On Shift-JIS encoded ROMs, <code>TxtGlueFindString</code> returns <code>true</code> if the string is located anywhere in the word.</p> |
| <b>Comments</b>    | Use this function instead of <a href="#">FindStrInStr()</a> to support the global system find facility. This function contains an extra parameter, <i>outLength</i> , to specify the length of the text that matched. Pass this value to <a href="#">FindSaveMatch()</a> in the <i>appCustom</i> parameter. Then when your application receives                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

sysAppLaunchCmdGoTo, the matchCustom field contains the length of the matching text. You use the length of matching text to highlight the match within the selected record.

You must make sure that the parameters inSourceStr and inTargetStr point to the start of a valid character. That is, they must point to the first byte of a multi-byte character, or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtFindString\(\)](#), [TxtCaselessCompare\(\)](#)

## **TxtGlueGetHorizEllipsisChar Function**

**Purpose** Return the horizontal ellipsis character.

**Declared In** TxtGlue.h

**Prototype** WChar TxtGlueGetHorizEllipsisChar (void)

**Parameters** None.

**Returns** Returns the character code for horizontal ellipsis.

**Comments** Versions 3.1 and higher of the Palm OS use different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use TxtGlueGetHorizEllipsisChar to return the appropriate code for horizontal ellipsis regardless of which version of Palm OS your application is run on.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [ChrHorizEllipsis\(\)](#), [TxtGlueGetNumericSpaceChar\(\)](#)

## **TxtGlueGetNumericSpaceChar Function**

**Purpose** Return the numeric space character.

**Declared In** TxtGlue.h

**Prototype** WChar TxtGlueGetNumericSpaceChar (void)

**Parameters** None.

**Returns** Returns the character code for numeric space.

- Comments** Versions 3.1 and higher of the Palm OS use different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use `TxtGlueGetNumericSpaceChar` to return the appropriate code for numeric space regardless of which version of Palm OS your application is run on.
- Compatibility** Implemented only in the PalmOSGlue library.
- See Also** [`ChrNumericSpace\(\)`](#), [`TxtGlueGetHorizEllipsisChar\(\)`](#)

## TxtGlueLowerChar Function

- Purpose** Convert a character to lowercase.
- Declared In** `TxtGlue.h`
- Prototype** `WChar TxtGlueLowerChar (WChar inChar)`
- Parameters**  $\rightarrow$  *inChar*  
A character.
- Returns** Returns the character as a lowercase letter.
- Comments** This function does not handle the case in which the lowercase version of a character is represented by two or more characters. If you need to handle this situation, call the [`TxtGlueLowerStr\(\)`](#) function instead of this one.
- Compatibility** Implemented only in the PalmOSGlue library.
- See Also** [`TxtGlueUpperChar\(\)`](#), [`TxtGlueLowerStr\(\)`](#), [`TxtGlueUpperStr\(\)`](#), [`TxtGlueTransliterate`](#), [`TxtTransliterate\(\)`](#), [`StrToLower\(\)`](#)

## TxtGlueLowerStr Function

- Purpose** Convert a string to all lowercase letters.
- Declared In** `TxtGlue.h`
- Prototype** `void TxtGlueLowerStr (Char* ioString, UInt16 inMaxLength)`
- Parameters**  $\leftrightarrow$  *ioString*  
The string to be converted.

→ *inMaxLength*

The size of the buffer that contains the string, excluding the terminating null character.

**Returns** Returns in `ioString` the input string with its letters converted to lowercase.

**Comments** Converting a string from uppercase to lowercase letters or vice versa may change the size of the string. For this reason, you should always check the size of the `ioString` after this call returns.

You must make sure that the parameter `ioString` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

This function can only handle characters in the ISO Latin 1 character encoding unless the [International Feature Set](#) is present.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtGlueUpperStr\(\)](#), [TxtGlueLowerChar\(\)](#),  
[TxtGlueUpperChar\(\)](#), [StrToLower\(\)](#)  
[TxtGlueTransliterate](#), [TxtTransliterate\(\)](#)

## **TxtGluePrepFindString Function**

**Purpose** Set up for [TxtFindString\(\)](#) or [FindStrInStr\(\)](#).

**Declared In** `TxtGlue.h`

**Prototype** `void TxtGluePrepFindString (const Char* inSource,  
CharPtr outDest, UInt16 inDstSize)`

**Parameters** → *inSource*

Pointer to the text to be searched for. Must not be NULL.

← *outDest*

The same text as in `inSource` but converted to a suitable format for searching. `outDest` must not be the same address as `inSource`.

→ *inDstSize*

The length in bytes of the area pointed to by `outDest`.

**Returns** Returns in `outDest` an appropriately converted string.

**Comments** Use this function to normalize the string to search for before using [TxtGlueFindString\(\)](#), [TxtFindString\(\)](#), or [FindStrInStr\(\)](#) to perform a search that is internal to your application. If you use any of these three search routines in response to the [sysAppLaunchCmdFind](#) launch code, the string that the launch code passes in is already properly normalized for the search.

This function normalizes the string to be searched for. The method by which a search string is normalized varies depending on the version of Palm OS and the character encoding supported by the device.

Only `inDstSize` bytes of `inSource` are written to `outDest`. If necessary to prevent overflow of the destination buffer, not all of `inSource` is converted.

You must make sure that the parameter `inSource` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

**Compatibility** Implemented only in the PalmOSGlue library.

## TxtGlueStripSpaces Function

**Purpose** Strip trailing and/or leading spaces from a string.

**Declared In** `TxtGlue.h`

**Prototype** `Char* TxtGlueStripSpaces (Char* ioStr, Boolean leading, Boolean trailing)`

**Parameters**

- $\leftrightarrow$  *ioStr*  
Any string.
- $\rightarrow$  *leading*  
If `true`, strip the leading spaces from the string.
- $\rightarrow$  *trailing*  
If `true`, strip the trailing spaces from the string.

**Returns** Returns `ioStr` with the specified spaces stripped from it. Note that this function both changes the `ioStr` buffer parameter and returns a pointer to it.

|                      |                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | You must make sure that the parameter <code>ioStr</code> points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable. |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                                  |

## **TxtGlueTruncateString Function**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Determine if a string can be displayed in a given number of pixels. If not, truncate the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | <code>TxtGlue.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | <code>Boolean TxtGlueTruncateString (Char *ioStringP,<br/>                                  UInt16 inMaxWidth)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>    | <p><math>\leftrightarrow</math> <i>ioStringP</i><br/>A null-terminated string. Upon return, the string is truncated if necessary so that it can be displayed in <code>inMaxWidth</code> pixels.</p> <p><math>\rightarrow</math> <i>inMaxWidth</i><br/>The maximum width in pixels.</p>                                                                                                                                                                                                                                                                                                                                                 |
| <b>Returns</b>       | Returns <code>true</code> if the string was truncated, or <code>false</code> if the string can fit without truncation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Comments</b>      | This function determines whether <code>ioStringP</code> can be displayed in the specified width without being truncated. If it can, <code>TxtGlueTruncateString</code> returns <code>false</code> . If the string must be truncated, this function truncates the string to one less than the number of characters that can fit in <code>inMaxWidth</code> and then appends an ellipsis (...) character. (If the boundary characters are narrower than the ellipsis, more than one character may be dropped to make room). If <code>inMaxWidth</code> is narrower than the width of an ellipsis, the string is set to the empty string. |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>See Also</b>      | <a href="#"><code>FntWidthToOffset()</code></a> , <a href="#"><code>WinDrawTruncChars()</code></a> ,<br><a href="#"><code>TxtGetTruncationOffset()</code></a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## **TxtGlueUpperChar Function**

|                      |                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert a character to uppercase.                                                                                                                                                                                                             |
| <b>Declared In</b>   | <code>TxtGlue.h</code>                                                                                                                                                                                                                        |
| <b>Prototype</b>     | <code>WChar TxtGlueUpperChar (WChar inChar)</code>                                                                                                                                                                                            |
| <b>Parameters</b>    | <code>→ inChar</code><br>Any character.                                                                                                                                                                                                       |
| <b>Returns</b>       | Returns the character as an uppercase letter.                                                                                                                                                                                                 |
| <b>Comments</b>      | This function does not handle the case in which the uppercase version of a character is represented by two or more characters. If you need to handle this situation, call the <a href="#">TxtGlueUpperStr()</a> function instead of this one. |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                   |
| <b>See Also</b>      | <a href="#">TxtGlueLowerChar()</a> , <a href="#">TxtGlueUpperStr()</a> , <a href="#">TxtGlueLowerStr()</a> , <a href="#">TxtGlueTransliterate</a> , <a href="#">TxtTransliterate()</a> , <a href="#">StrToLower()</a>                         |

## **TxtGlueUpperStr Function**

|                    |                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a string to all uppercase letters.                                                                                                                                                                       |
| <b>Declared In</b> | <code>TxtGlue.h</code>                                                                                                                                                                                           |
| <b>Prototype</b>   | <code>void TxtGlueUpperStr (Char* ioString,<br/>                        UInt16 inMaxLength)</code>                                                                                                               |
| <b>Parameters</b>  | <code>↔ ioString</code><br>The string to be converted.<br><code>→ inMaxLength</code><br>The size of the buffer that contains the string, excluding the terminating null character.                               |
| <b>Returns</b>     | Returns in <code>ioString</code> the input string with its letters converted to uppercase.                                                                                                                       |
| <b>Comments</b>    | Converting a string from uppercase to lowercase letters or vice versa may change the size of the string. For this reason, you should always check the size of the <code>ioString</code> after this call returns. |

You must make sure that the parameter `ioString` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

This function can only handle characters in the ISO Latin 1 character encoding unless the [International Feature Set](#) is present.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtGlueLowerStr\(\)](#), [TxtGlueUpperChar\(\)](#),

## UIColorGlueGetNumTableEntries Function

**Purpose** Get the number of entries in the UI color table.

**Declared In** `UIColorGlue.h`

**Prototype** `UInt16 UIColorGlueGetNumTableEntries (void)`

**Parameters** None.

**Returns** Returns the number of color table entries. Note that this is one greater than the maximum value that can be passed to [UIColorGetTableEntryIndex\(\)](#), [UIColorGetTableEntryRGB\(\)](#), and [UIColorSetTableEntry\(\)](#).

## WinGlueGetFrameType Function

**Purpose** Gets the frame type for a specified window.

**Declared In** `WinGlue.h`

**Prototype** `FrameType WinGlueGetFrameType  
(const WinHandle winH)`

**Parameters**  $\rightarrow$  `winH`  
The window's handle.

**Returns** Returns a `FrameType` value indicating the window's frame style.

**See Also** [WinGlueSetFrameType\(\)](#)

## **WinGlueSetFrameType Function**

- Purpose** Sets the type of frame to be used for a specified window.
- Declared In** `WinGlue.h`
- Prototype** `void WinGlueSetFrameType (WinHandle winH,  
FrameType frame)`
- Parameters**
- *winH*  
The window's handle.
  - *frame*  
The style of frame to be used.
- Returns** Returns nothing.
- See Also** [WinGlueGetFrameType\(\)](#)

# Bluetooth Library: General Functions

---

The Bluetooth library is a shared library that provides a direct interface to the Bluetooth communication capability of the Palm OS. This chapter presents reference material for the security and utility functions of the Bluetooth library API:

## Security Functions

Describes security functions that allow the application to manage a database of trusted devices. Trusted devices don't need to undergo authentication when they reconnect with the local device.

## Utility Functions

Describes utility functions and macros that are useful when working with the Bluetooth library. They perform such tasks as converting between host and network byte ordering, and converting between device addresses and strings.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Security Functions

The Bluetooth security functions allow the application to manage a database of devices that have been bonded or paired. To understand this database, it is important to understand the difference between pairing and bonding.

Typically, devices must authenticate with each other every time they connect to each other. This process is called *pairing*. However, the devices can *bond* instead. Bonding is similar to pairing except that both devices remember the link key for the connection. If the two

## Bluetooth Library: General Functions

### *BtLibSecurityFindTrustedDeviceRecord*

---

devices ever want to connect to each other again, they don't need to repeat the pairing process.

Information about paired and bonded devices is stored in a device database on the local device. If a remote device has bonded with the local device, its record remains in the database until it is explicitly deleted. If the remote device has paired with the local device but not bonded with it, the record is removed when the connection to the remote device terminates.

Remote devices that have bonded with the local device are also called *trusted devices*.

### **BtLibSecurityFindTrustedDeviceRecord Function**

|                    |                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Search the device database for the device with the specified Bluetooth address. Return the index of the corresponding device record in the database.                                     |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>Err BtLibSecurityFindTrustedDeviceRecord     (UInt16 btLibRefNum,      BtLibDeviceAddressTypePtr addrP,      UInt16 *index)</pre>                                                   |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>addrP</i><br/>Bluetooth address of remote device.</p> <p>← <i>index</i><br/>Index of the record.</p> |
| <b>Returns</b>     | Returns <code>btLibErrNoError</code> if successful. Returns <code>btLibErrNotFound</code> if a record with the specified remote device address could not be found.                       |
| <b>See Also</b>    | <a href="#"><code>BtLibSecurityRemoveTrustedDeviceRecord()</code></a> ,<br><a href="#"><code>BtLibSecurityGetTrustedDeviceRecordInfo()</code></a>                                        |

## **BtLibSecurityGetTrustedDeviceRecordInfo Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Get information from a device record in the device database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <pre>Err BtLibSecurityGetTrustedDeviceRecordInfo     (UInt16 btLibRefNum, UInt16 index,      BtLibDeviceAddressTypePtr addrP,      Char *nameBuffer,      UInt8 *nameBufferSize,      BtLibClassOfDeviceType *cod,      Boolean *persistent)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <div><div>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</div><div>→ <i>index</i><br/>Index of the record.</div><div>← <i>addrP</i><br/>Bluetooth address of remote device.</div><div>← <i>nameBuffer</i><br/>Pointer to buffer to store user-friendly name of remote device. You must allocate this buffer. Provide a NULL pointer if the user-friendly name is not needed.</div><div>↔ <i>nameBufferSize</i><br/>Size of the nameBuffer buffer on entry. On exit, the size of the name.</div><div>← <i>cod</i><br/>Pointer to a <a href="#">BtLibClassOfDeviceType</a> representing the class of the device. You must allocate this structure. Provide a NULL pointer if the device class is not needed.</div><div>← <i>lastConnected</i><br/>The date since the device last connected. This date is measured in seconds since midnight January 1, 1904. Provide a NULL pointer if the date of last connection is not needed.</div><div>← <i>persistent</i><br/>If true, the device is bonded and can connect to the local device without authentication. If false, the device is paired but not bonded—it will need to reauthenticate if it connects</div></div> |

## Bluetooth Library: General Functions

### *BtLibSecurityNumTrustedDeviceRecords*

---

again. Provide a NULL pointer if this information is not needed.

**Returns** Returns `btLibErrNoError` if successful. Returns `dmErrIndexOutOfRange` if a record with the specified index could not be found.

**See Also** [BtLibSecurityFindTrustedDeviceRecord\(\)](#)

## **BtLibSecurityNumTrustedDeviceRecords Function**

**Purpose** Return the number of bonded devices in the device database or return the total number of devices in the device database.

**Declared In** `BtLib.h`

**Prototype** `UInt16 BtLibSecurityNumTrustedDeviceRecords  
(UInt16 btLibRefNum, Boolean persistentOnly)`

**Parameters**   
→ *btLibRefNum*  
Reference number for the Bluetooth library.  
→ *persistentOnly*  
true to obtain the total number of bonded devices in the database. These are the same devices that appear in the trusted devices list. false to obtain the total number of devices in the device database. This includes the devices that are bonded and the devices that are paired but not bonded.

**Returns** Returns the requested number of device records.

**See Also** [BtLibSecurityFindTrustedDeviceRecord\(\)](#),  
[BtLibSecurityGetTrustedDeviceRecordInfo\(\)](#)

## BtLibSecurityRemoveTrustedDevice Record Function

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Remove a device record from the device database.                                                                                                       |
| <b>Declared In</b> | BtLib.h                                                                                                                                                |
| <b>Prototype</b>   | Err BtLibSecurityRemoveTrustedDeviceRecord<br>(UInt16 btLibRefNum, UInt16 index)                                                                       |
| <b>Parameters</b>  | → <i>btLibRefNum</i><br>Reference number for the Bluetooth library.<br>→ <i>index</i><br>Index of the record to remove.                                |
| <b>Returns</b>     | Returns <code>btLibErrNoError</code> if successful. Returns <code>dmErrIndexOutOfRange</code> if a record with the specified index could not be found. |
| <b>See Also</b>    | <a href="#">BtLibSecurityFindTrustedDeviceRecord()</a>                                                                                                 |

## Utility Functions

This section describes functions and macros that are useful when working with the Bluetooth library.

### BtLibAddrAToBtd Function

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert an ASCII string a Bluetooth device address in colon-separated form to a 48-bit <a href="#">BtLibDeviceAddressType</a> .                                    |
| <b>Declared In</b> | BtLib.h                                                                                                                                                            |
| <b>Prototype</b>   | Err BtLibAddrAToBtd (UInt16 btLibRefNum,<br>const Char *addressString,<br>BtLibDeviceAddressType *btDevP)                                                          |
| <b>Parameters</b>  | → <i>btLibRefNum</i><br>Reference number for the Bluetooth library.<br>→ <i>addressString</i><br>String containing ASCII colon-separated Bluetooth device address. |

## Bluetooth Library: General Functions

### *BtLibAddrBtdToA*

---

← *btDevP*

Pointer to a [BtLibDeviceAddressType](#) to store the converted device address.

**Returns** Returns `btLibErrNoError` to indicate that the conversion was successful.

**See Also** [BtLibAddrBtdToA\(\)](#)

## BtLibAddrBtdToA Function

**Purpose** Convert 48-bit [BtLibDeviceAddressType](#) to an ASCII string in colon-separated form.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibAddrBtdToA (UInt16 btLibRefNum,  
BtLibDeviceAddressType *btDevP, Char *spaceP,  
UInt16 spaceSize)`

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *btDevP*  
Address of a Bluetooth device. This parameter must not be NULL.
- ← *spaceP*  
Pointer to a buffer to store the ASCII formatted Bluetooth devices address upon return. This parameter must not be NULL.
- *spaceSize*  
Size of the *spaceP* buffer, in bytes. Must be at least 18.

**Returns** Returns `btLibErrNoError` if successful. Returns `btLibErrParamErr` if

- *btDevP* is NULL
- *spaceP* is NULL
- *spaceSize* is less than 18, the number of bytes required to store the ASCII formatted address

**See Also** [BtLibAddrAToBtd\(\)](#)

## BtLibL2CapHToNL Macro

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 32-bit value from host to L2CAP byte order. L2CAP byte order is little endian.                                                           |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                |
| <b>Prototype</b>   | <code>#define BtLibL2CapHToNL (value)</code>                                                                                                        |
| <b>Parameters</b>  | <code>→ value</code><br>32-bit value to convert.                                                                                                    |
| <b>Returns</b>     | Returns value in L2CAP byte order.                                                                                                                  |
| <b>See Also</b>    | <a href="#"><code>BtLibL2CapHToNS()</code></a> , <a href="#"><code>BtLibL2CapNToHL()</code></a> ,<br><a href="#"><code>BtLibL2CapNToHS()</code></a> |

## BtLibL2CapHToNS Macro

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 16-bit value from host to L2CAP byte order. L2CAP byte order is little endian.                                                         |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                              |
| <b>Prototype</b>   | <code>#define BtLibL2CapHToNS (value)</code>                                                                                                      |
| <b>Parameters</b>  | <code>→ value</code><br>16-bit value to convert.                                                                                                  |
| <b>Returns</b>     | Returns value in L2CAP byte order.                                                                                                                |
| <b>See Also</b>    | <a href="#"><code>BtLibL2CapHToNL()</code></a> , <a href="#"><code>BtLibL2CapNToHS()</code></a> ,<br><a href="#"><code>BtLibSdpNToHL()</code></a> |

## BtLibL2CapNToHL Macro

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 32-bit value from L2CAP to host byte order. L2CAP byte order is little endian. |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                      |
| <b>Prototype</b>   | <code>#define BtLibL2CapNToHL (value)</code>                                              |
| <b>Parameters</b>  | <code>→ value</code><br>32-bit value to convert.                                          |

## Bluetooth Library: General Functions

*BtLibL2CapNToHS*

---

**Returns** Returns value in host byte order.

**See Also** [BtLibL2CapNToHS\(\)](#), [BtLibL2CapHToNL\(\)](#),  
[BtLibL2CapHToNS\(\)](#)

### BtLibL2CapNToHS Macro

**Purpose** Converts a 16-bit value from L2CAP to host byte order. L2CAP byte order is little endian.

**Declared In** BtLib.h

**Prototype** `#define BtLibL2CapNToHS (value)`

**Parameters** `→ value`  
16-bit value to convert.

**Returns** Returns value in host byte order.

**See Also** [BtLibL2CapNToHL\(\)](#), [BtLibL2CapHToNS\(\)](#),  
[BtLibL2CapHToNL\(\)](#)

### BtLibRfCommHToNL Macro

**Purpose** Converts a 32-bit value from host to RFCOMM byte order. RFCOMM byte order is big endian.

**Declared In** BtLib.h

**Prototype** `#define BtLibRfCommHToNL (value)`

**Parameters** `→ value`  
32-bit value to convert

**Returns** Returns value in RFCOMM byte order.

**See Also** [BtLibRfCommHToNS\(\)](#), [BtLibRfCommNToHL\(\)](#),  
[BtLibRfCommNToHS\(\)](#)

## **BtLibRfCommHToNS Macro**

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 16-bit value from host to RFCOMM byte order. RFCOMM byte order is big endian.                        |
| <b>Declared In</b> | BtLib.h                                                                                                         |
| <b>Prototype</b>   | #define BtLibRfCommHToNS (value)                                                                                |
| <b>Parameters</b>  | → <i>value</i><br>16-bit value to convertx                                                                      |
| <b>Returns</b>     | Returns value in RFCOMM byte order.                                                                             |

## **BtLibRfCommNToHS Macro**

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 16-bit value from RFCOMM to host byte order. RFCOMM byte order is big endian. |
| <b>Declared In</b> | BtLib.h                                                                                  |
| <b>Prototype</b>   | #define BtLibRfCommNToHS (value)                                                         |
| <b>Parameters</b>  | → <i>value</i><br>16-bit value to convertx                                               |

## Bluetooth Library: General Functions

*BtLibSdpHToNL*

---

**Returns** Returns value in host byte order.

**See Also** [BtLibRfCommNToHL\(\)](#), [BtLibRfCommHToNS\(\)](#),  
[BtLibRfCommHToNL\(\)](#)

### BtLibSdpHToNL Macro

**Purpose** Converts a 32-bit value from host to Service Discovery Protocol (SDP) byte order. SDP byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `#define BtLibSdpHToNL (value)`

**Parameters** `→ value`  
32-bit value to convertx

**Returns** Returns value in SDP byte order.

**See Also** [BtLibSdpHToNS\(\)](#), [BtLibSdpNToHL\(\)](#), [BtLibSdpNToHS\(\)](#)

### BtLibSdpHToNS Macro

**Purpose** Converts a 16-bit value from host to Service Discovery Protocol (SDP) byte order. SDP byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `#define BtLibSdpHToNS (value)`

**Parameters** `→ value`  
16-bit value to convertx

**Returns** Returns value in SDP byte order.

**See Also** [BtLibSdpHToNL\(\)](#), [BtLibSdpNToHS\(\)](#), [BtLibSdpNToHL\(\)](#)

**BtLibSdpNToHL Macro**

|                    |                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a 32-bit value from Service Discovery Protocol (SDP) to host byte order. SDP byte order is big endian.                              |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                         |

## Bluetooth Library: General Functions

*BtLibSdpNToHS*

---

# Bluetooth Library: Management

---

The management API of the Bluetooth library supports the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. This chapter presents reference material for the management API:

## [Bluetooth Management Data Structures](#)

This section lists some of the more important types used by the Bluetooth library management functions.

## [Management Callback Events](#)

This section lists the management callback events. Most of the management functions are asynchronous. In other words, they start operations and return before the operations complete. To signal the application that management operations have completed, the Bluetooth library generates *management callback events* by calling a callback function.

## [Management Event Status Codes](#)

When a management event is generated, the status field of the associated [BtLibManagementEventType](#) provides information about why the event occurred. This section explains what these codes mean.

## [Library Management Functions](#)

This section describes the functions that open and close the shared library.

## [Management Functions](#)

The management functions handle the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. These functions perform tasks that include discovering devices, working with Asynchronous Connectionless (ACL) links and piconets, and maintaining global settings for the Bluetooth library.

## Bluetooth Library: Management

### Bluetooth Management Data Structures

---

#### [Application-Defined Functions](#)

This section describes the callback functions that handle management events.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Bluetooth Management Data Structures

This section lists some of the more important types used by the Bluetooth library management functions.

### BtLibAccessibleModeEnum Enum

**Purpose** The `BtLibAccessibleModeEnum` enum specifies a device's accessibility modes. See the "Generic Access Profile" chapter of the *Specification of the Bluetooth System* for more information about accessibility.

**Prototype**

```
typedef enum {  
    btLibNotAccessible = 0x00,  
    btLibConnectableOnly = 0x02,  
    btLibDiscoverableAndConnectable = 0x03  
} BtLibAccessibleModeEnum;
```

#### Value Descriptions

`btLibConnectableOnly`

The device responds to a page but not an inquiry.

`btLibDiscoverableAndConnectable`

The device responds to both a page and an inquiry.

`btLibNotAccessible`

The device does not respond to a page or an inquiry.

## BtLibClassOfDeviceType Typedef

**Purpose** The `BtLibClassOfDeviceType` type represents the class of the device and the services it supports.

**Prototype** `typedef UInt32 BtLibClassOfDeviceType;`

A device can support multiple services but only belongs to a single class. The class is specified in two parts: the major class, which broadly classifies the type of device, and the minor class, which together with the major class specifies the type of device in more detail.

An example is a simple cellular telephone. It provides Telephony services. Its major device class is Phone, and its minor device class is Cellular.

The *Bluetooth Assigned Numbers* specification defines a device class as having three bit fields. One field specifies the major service classes supported by the device. Another field specifies the major device class. The third field specifies the minor device class.

The constants provided here allow you to construct a device class that conforms to the Bluetooth specification. You simply perform a logical OR of the constants representing the service classes the device supports, the constant representing the device's major class, and the constant representing the device's minor class.

For example, device class of the simple cellular telephone can be computed as follows:

---

```
cellPhoneCOD = btLibCOD_Telephony |  
               btLibCOD_Major_Phone |  
               BtLibCOD_Minor_Phone_Cellular;
```

---

Constants are also provided to mask the individual bit fields in a device class.

### Major Service Classes

These constants define the Bluetooth major service classes. The service classes are described in the *Specification of the Bluetooth System*.

**Constants** `btLibCOD_LimitedDiscoverableMode`

## Bluetooth Library: Management

*BtLibClassOfDeviceType*

---

```
btLibCOD_Networking
btLibCOD_Rendering
btLibCOD_Capturing
btLibCOD_ObjectTransfer
btLibCOD_Audio
btLibCOD_Telephony
btLibCOD_Information
```

### Major Device Classes

These constants define the Bluetooth major device classes. The major device classes are described in the *Specification of the Bluetooth System*.

|                  |                                                                                                                                                                                        |

### Computer Minor Device Classes

These constants define the minor device classes associated with the computer major class. They are described in the *Bluetooth Assigned Numbers* specification.

|                  |                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Constants</b> | <pre>btLibCOD_Minor_Comp_Unclassified btLibCOD_Minor_Comp_Desktop btLibCOD_Minor_Comp_Server btLibCOD_Minor_Comp_Laptop btLibCOD_Minor_Comp_Handheld btLibCOD_Minor_Comp_Palm</pre> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Phone Minor Device Classes**

These constants define the minor device classes are associated with the computer major class. They are described in the *Bluetooth Assigned Numbers* specification.

**Constants**

- `btLibCOD_Minor_Phone_Unclassified`
- `btLibCOD_Minor_Phone_Cellular`
- `btLibCOD_Minor_Phone_Cordless`
- `btLibCOD_Minor_Phone_Smart`
- `btLibCOD_Minor_Phone_Modem`

### **LAN Access Point Minor Device Classes**

These constants define load factors for the LAN access point major device class. LAN access point load factors are described in more detail in the *Bluetooth Assigned Numbers* specification.

**Constants**

- `btLibCOD_Minor_Lan_0`  
Fully available
- `btLibCOD_Minor_Lan_17`  
1-17% utilized
- `btLibCOD_Minor_Lan_33`  
17-33% utilized
- `btLibCOD_Minor_Lan_50`  
33-50% utilized
- `btLibCOD_Minor_Lan_67`  
50-67% utilized
- `btLibCOD_Minor_Lan_83`  
67-83% utilized
- `btLibCOD_Minor_Lan_99`  
83-99% utilized
- `btLibCOD_Minor_Lan_NoService`  
Fully utilized

### Audio Minor Device Classes

These constants define the minor classes associated with the audio major class. They are described in more detail in the *Bluetooth Assigned Numbers* specification.

**Constants**    `btLibCOD_Minor_Audio_Unclassified`  
`btLibCOD_Minor_Audio_Headset`

### Masks

These constants define bit masks to isolate certain fields of the device class.

**Constants**    `btLibCOD_Service_Mask`  
                  A mask to isolate the major service class field from the other fields of the device class.

`btLibCOD_Major_Mask`  
                  A mask to isolate the major device class field from the other fields of the device class.

`btLibCOD_Minor_Mask`  
                  A mask to isolate the minor device class field from the other fields of the device class.

`btLibCOD_ServiceAny`  
                  Used as a device filter for the [`BtLibDiscoverMultipleDevices\(\)`](#) and [`BtLibDiscoverSingleDevice\(\)`](#) functions. With this filter, devices providing any service appear in the device list. Same as `btLibCOD_Service_Mask`.

`btLibCOD_Major_Any`  
                  Used as a device filter for the [`BtLibDiscoverMultipleDevices\(\)`](#) and [`BtLibDiscoverSingleDevice\(\)`](#) functions. With this filter, devices in any major device class appear in the device list. Same as `btLibCOD_Major_Mask`.

`btLibCOD_Minor_Any`  
                  Used as a device filter for the [`BtLibDiscoverMultipleDevices\(\)`](#) and [`BtLibDiscoverSingleDevice\(\)`](#) functions. With this filter, devices in any minor device class appear in the device list. Same as `btLibCOD_Minor_Mask`.

`btLibCOD_Minor_Comp_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices\(\)](#) and [BtLibDiscoverSingleDevice\(\)](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Computer`, all devices broadcasting themselves as computers appear in the device list. Same as `btLibCOD_Minor_Any`.

`btLibCOD_Minor_Phone_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices\(\)](#) and [BtLibDiscoverSingleDevice\(\)](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Phone`, all devices broadcasting themselves as phones appear in the device list. Same as `btLibCOD_Minor_Any`.

`btLibCOD_Minor_LAN_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices\(\)](#) and [BtLibDiscoverSingleDevice\(\)](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Lan_Access_Point`, all devices broadcasting themselves as LAN access points appear in the device list. Same as `btLibCOD_Minor_Any`.

`btLibCOD_Minor_Audio_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices\(\)](#) and [BtLibDiscoverSingleDevice\(\)](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Audio`, all devices broadcasting themselves as audio devices appear in the device list. Same as `btLibCOD_Minor_Any`.

## **BtLibConnectionRoleEnum Enum**

**Purpose** The `BtLibConnectionRoleEnum` enum specifies all the connection roles a device can have. A device can either be a master or a slave.

**Prototype**

```
typedef enum {  
    btLibMasterRole,  
    btLibSlaveRole
```

## Bluetooth Library: Management

### *BtLibDeviceAddressType*

---

```
} BtLibConnectionRoleEnum;
```

#### Value Descriptions

`btLibMasterRole`  
The device is a master.

`btLibSlaveRole`  
The device is a slave.

### BtLibDeviceAddressType Struct

**Purpose** The `BtLibDeviceAddressType` structure represents a 48-bit Bluetooth device address.

**Prototype**

```
#define btLibDeviceAddressSize 6

typedef struct BtLibDeviceAddressType {
    UInt8 address[btLibDeviceAddressSize];
} BtLibDeviceAddressType;
```

### BtLibFriendlyNameType Struct

**Purpose** The `BtLibFriendlyNameType` structure contains the user-friendly name of a device.

**Prototype**

```
typedef struct BtLibFriendlyNameType {
    UInt8 *name;
    UInt8 nameLength;
} BtLibFriendlyNameType,
*BtLibFriendlyNameTypePtr;
```

#### Field Descriptions

`name`  
Array of characters, encoded according to the UTF-8 standard, containing the user-friendly name of the device. This array is not null-terminated.

`nameLength`  
The number of characters in the user-friendly name. The maximum size is 249 characters.

## BtLibManagementEventType Struct

**Purpose** The BtLibManagementEventType structure contains detailed information regarding a management callback event. All management events have some common data. Most management events have data specific to those events. The specific data uses a union that is part of the BtLibManagementEvent data structure.

**Prototype**

```
typedef struct _BtLibManagementEventType {  
    BtLibManagementEventEnum event;  
    Err status;  
    union {  
        ...  
    } eventData;  
} BtLibManagementEventType;
```

### Field Descriptions

event

A BtLibManagementEventEnum enum member that indicates which management event has occurred. See [Management Callback Events](#).

status

Status of the event. The [Management Callback Events](#) section gives more details about how to interpret this field for specific events.

eventData

Data associated with the event. The member of this union that is valid depends on the event. See [Management Callback Events](#) for more information.

A BtLibManagementEventType object is passed as the first argument of the [BtLibManagementCallback\(\)](#) callback function.

## Management Callback Events

The management functions of the Bluetooth library support the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. Most of the management functions are asynchronous. In other words, they start operations and return before the operations complete. To signal the

## Bluetooth Library: Management

### *btLibManagementEventAccessibilityChange*

---

application that management operations have completed, the Bluetooth library generates *management callback events* by calling a callback function.

You specify the callback function using the [BtLibRegisterManagementNotification\(\)](#) function. When an event occurs, the callback function is called with two parameters: a pointer to a [BtLibManagementEventType](#) structure and a pointer to a user-defined structure.

The `BtLibManagementEventType` structure contains an event field, which indicates the reason the callback is called, a status field, which contains status information associated with the event, and a union of several structures. The member of the union that is valid depends on the event. The meaning of the events is described in the following sections.

For more information about the status field, see [Management Event Status Codes](#).

### **btLibManagementEventAccessibilityChange**

The accessibility mode of the local device has changed.

For this event, the `eventData` field contains the following field:

```
BtLibAccessibleModeEnum accessible;
```

This [BtLibAccessibleModeEnum](#) represents the new accessibility mode of the local device.

This event can result from calling [BtLibOpen\(\)](#), [BtLibPiconetCreate\(\)](#), or [BtLibSetGeneralPreference\(\)](#).

### **btLibManagementEventAclConnectInbound**

A remote device has established an ACL link to the local device.

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

## **btLibManagementEventAclConnectOutbound**

An ACL link has been established with a remote device.

If the `status` field contains `btLibErrNoError`, the ACL link is connected, and the remote device address can be found in the `eventData` field. Otherwise the connection failed and the `status` field indicates the reason for the failure. See [Management Event Status Codes](#) for more information.

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

This event can result from calling [BtLibLinkConnect\(\)](#).

## **btLibManagementEventAclDisconnect**

An ACL link has been disconnected. The `status` field indicates the reason the link was disconnected. See [Management Event Status Codes](#).

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contain the address of the disconnected device.

This event can result from calling [BtLibLinkDisconnect\(\)](#) or [BtLibPiconetDestroy\(\)](#).

## **btLibManagementEventAuthentication Complete**

The authentication of a remote device has completed.

## Bluetooth Library: Management

### *btLibManagementEventEncryptionChange*

---

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

If the authentication is successful, the `status` field contains `btLibErrNoError`. If the user cancels the passkey request, the `status` field contains `btLibErrCanceled`. Otherwise, the `status` field indicates the reason the authentication failed. See [Management Event Status Codes](#).

This event can result from calling [BtLibLinkSetState\(\)](#).

## btLibManagementEventEncryptionChange

**Purpose** Encryption for a link has been enabled or disabled.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    Boolean enabled;  
} encryptionChange;
```

### Field Descriptions

`bdAddr`

A [BtLibDeviceAddressType](#) containing the address of the remote device.

`enabled`

true when encryption for the link has been enabled; false otherwise.

This event can result from calling [BtLibLinkSetState\(\)](#).

## btLibManagementEventInquiryCanceled

The device inquiry has been canceled because the application called [BtLibCancelInquiry\(\)](#).

## btLibManagementEventInquiryComplete

The device inquiry started with the [BtLibStartInquiry\(\)](#) function has completed.

## btLibManagementEventInquiryResult

**Purpose** A remote device has responded to an inquiry that was started with the [BtLibStartInquiry\(\)](#) function.

For this event, the eventData field contains the following structure:

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibClassOfDeviceType classOfDevice;  
} inquiryResult;
```

### Field Descriptions

bdAddr

A [BtLibDeviceAddressType](#) containing the address of the remote device.

classOfDevice

A [BtLibClassOfDeviceType](#) representing the class of the remote device.

## btLibManagementEventLocalNameChange

**Purpose** The user-friendly name of the local device has changed.  
For this event, the eventData field contains the following structure:

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibFriendlyNameType name;  
} nameResult;
```

### Field Descriptions

bdAddr

A [BtLibDeviceAddressType](#) containing the address of the local device.

name

A [BtLibFriendlyNameType](#) containing the new name.

This event can result from calling [BtLibOpen\(\)](#).

## btLibManagementEventModeChange

**Purpose** A slave has changed its mode. A slave can be in active, sniff, hold, or park mode.

For this event, the eventData field contains the following structure:

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibLinkModeEnum curMode;  
    UInt16 interval;  
} modeChange;
```

### Field Descriptions

bdAddr

A [BtLibDeviceAddressType](#) containing the address of the remote device.

curMode

A [BtLibLinkModeEnum](#) indicating the new mode of remote device

interval

The time in units of 0.625 ms the remote device will stay in the new mode, if applicable. The time period is a standard time period in the Bluetooth specification.

### **BtLibLinkModeEnum**

**Purpose** The BtLibLinkModeEnum enum specifies the modes a slave can have. According to the *Specification of the Bluetooth System*, a slave can be in active, sniff, hold, or park mode. However, the Bluetooth library only supports the hold and active modes.

**Prototype**

```
typedef enum {
    btLibSniffMode,
    btLibHoldMode,
    btLibParkMode,
    btLibActiveMode
} BtLibLinkModeEnum;
```

### **Value Descriptions**

btLibActiveMode  
The slave is active.

btLibHoldMode  
The slave is in hold mode.

btLibParkMode  
The slave is in park mode. This mode is not currently supported.

btLibSniffMode  
The slave is in sniff mode. This mode is not currently supported.

## **btLibManagementEventNameResult**

**Purpose** A remote device name request has completed. If the status field is btLibErrNoError, the name is available. Otherwise, the name request failed, and the status field indicates the reason for the failure. See [Management Event Status Codes](#).

For this event, the eventData field contains the following structure:

## Bluetooth Library: Management

### *btLibManagementEventPairingComplete*

---

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibFriendlyNameType name;  
} nameResult;
```

#### Field Descriptions

bdAddr

A [BtLibDeviceAddressType](#) containing the address of the remote device.

name

A [BtLibFriendlyNameType](#) containing the name of the remote device.

The [BtLibGetRemoteDeviceName\(\)](#) function is used to start a remote device name request.

## btLibManagementEventPairingComplete

Pairing has successfully completed and the link is authenticated. The status code for this event is set to `btLibErrNoError`, indicating that the link key was stored successfully.

If pairing fails, no event is sent (there is no event sent by the radio module indicating failure).

## btLibManagementEventPasskeyRequest

A remote device has requested a passkey. Your application does not have to respond to this request—the Bluetooth library automatically handles it.

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

Because a passkey can be requested during or after a link is established, consider disabling any failure timers while the passkey

dialog is up. The [btLibManagementEventPasskeyRequestComplete](#) event signals the completion of the passkey entry.

## **btLibManagementEventPasskeyRequestComplete**

A passkey request has been processed. The status code for this event is set to `btLibErrNoError` if the passkey was entered or `btLibErrCanceled` if passkey entry was cancelled. Note that this event does **not** tell you that the authentication completed.

## **btLibManagementEventPiconetCreated**

The piconet has been created. This event can result from calling [BtLibPiconetCreate\(\)](#).

## **btLibManagementEventPiconetDestroyed**

The piconet has been destroyed. This event can result from calling [BtLibPiconetDestroy\(\)](#).

## **btLibManagementEventRadioState**

This event is generated when the Bluetooth radio changes state. The radio changes state when the radio is disconnected, the power is turned on or off, the radio resets, or the radio fails to initialize. The status code for this event explains why the event gets generated.

### **Status Codes**

`btLibErrRadioInitialized`

The Bluetooth radio has initialized successfully. You can now call management functions.

`btLibErrRadioInitFailed`

The Bluetooth radio failed to initialize. The application can assume all pending Bluetooth operations have failed.

## Bluetooth Library: Management

### *btLibManagementEventRadioState*

---

However, some pending operations will still generate events and modify memory supplied by the application.

To try to initialize the radio again, you need to close the library and reopen it.

#### `btLibErrRadioFatal`

A fatal radio error occurred. This usually signifies that the host has lost contact with the radio, for example, when the user disconnects the radio, or the device turns off. The application can assume that all pending operations have failed. However, some pending operations will still generate events and modify memory supplied by the application.

When a fatal radio error occurs, the Bluetooth stack resets the radio and tries once to reinitialize it, which generates another `btLibManagementEventRadioState` event with a status code of `btLibErrRadioInitialized`, or `btLibErrRadioInitFailed` depending on whether or not the initialization succeeded.

#### `btLibErrRadioSleepWake`

The radio was reset because the device went to sleep. The application can assume all pending operations have failed. However, some pending operations will still generate events and modify memory supplied by the application.

The Bluetooth stack resets the radio and tries once to reinitialize it, which generates another `btLibManagementEventRadioState` event with a status code of `btLibErrRadioInitialized`, or `btLibErrRadioInitFailed` depending on whether or not the initialization succeeded.

This event can result from calling [`BtLibOpen\(\)`](#).

## **btLibManagementEventRoleChange**

**Purpose** The master and slave devices for a link have switched roles.  
For this event, the eventData field contains the following structure:

**Prototype**

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibConnectionRoleEnum newRole;  
} roleChange;
```

### **Field Descriptions**

bdAddr

A [BtLibDeviceAddressType](#) containing the address of the remote device.

newRole

A [BtLibConnectionRoleEnum](#) representing the new role of the local device.

## **Management Event Status Codes**

When a management event is generated, the status field of the associated [BtLibManagementEventType](#) provides information about why the event occurred. The following status codes can occur with a management event.

btLibErrNoError  
Success.

btLibMeStatusAuthenticateFailure  
Authentication failure

btLibMeStatusCommandDisallowed  
Command disallowed

btLibMeStatusConnnectionTimeout  
Connection timeout

btLibMeStatusHardwareFailure  
Hardware Failure

btLibMeStatusHostTimeout  
Host timeout

## Bluetooth Library: Management

### *Management Event Status Codes*

---

btLibMeStatusInvalidHciParam  
Invalid HCI command parameters

btLibMeStatusInvalidLmpParam  
Invalid LMP Parameters

btLibMeStatusLimitedResources  
Host rejected due to limited resources

btLibMeStatusLmpResponseTimeout

btLibMeStatusLmpTransdCollision

btLibMeStatusLmpPduNotAllowed

btLibMeStatusLocalTerminated  
Terminated by local host

btLibMeStatusLowResources  
Other end terminated due to low resources

btLibMeStatusMaxAclConnections  
Max number of ACL connections to a device

btLibMeStatusMaxConnections  
Max number of connections

btLibMeStatusMaxScoConnections  
Max number of SCO connections to a device

btLibMeStatusMemoryFull  
Memory full

btLibMeStatusMissingKey  
Missing key

btLibMeStatusNoConnection  
No connection

btLibMeStatusPageTimeout  
Page timeout

btLibMeStatusPairingNotAllowed  
Pairing not allowed

btLibMeStatusPersonalDevice  
Host rejected (remote is personal device)

`btLibMeStatusPowerOff`  
Other end terminated (about to power off)

`btLibMeStatusRepeatedAttempts`  
Repeated attempts

`btLibMeStatusRoleChangeNotAllowed`  
Change not allowed

`btLibMeStatusScoAirModeRejected`  
SCO Air Mode Rejected

`btLibMeStatusScoIntervalRejected`  
SCO Interval Rejected

`btLibMeStatusScoOffsetRejected`  
SCO Offset Rejected

`btLibMeStatusSecurityError`  
Host rejected due to security reasons

`btLibMeStatusUnknownHciCommand`  
Unknown HCI Command

`btLibMeStatusUnknownLmpPDU`  
Unknown LMP PDU

`btLibMeStatusUnspecifiedError`  
Unspecified Error

`btLibMeStatusUnsupportedFeature`  
Unsupported feature or parameter value

`btLibMeStatusUnsupportedLmpParam`  
Unsupported LMP Parameter Value

`btLibMeStatusUnsupportedRemote`  
Unsupported Remote Feature

`btLibMeStatusUserTerminated`  
Other end terminated (user)

## Library Management Functions

This section describes the general Bluetooth library management functions.

## Bluetooth Library: Management

*BtLibClose*

---

### BtLibClose Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Close the Bluetooth library.                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Prototype</b>   | <code>Err BtLibClose (UInt16 btLibRefNum)</code>                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <code>→ btLibRefNum</code><br>Reference number for the Bluetooth library.                                                                                                                                                                                                                                                                                                                                    |
| <b>Returns</b>     | Returns <code>btLibErrNoError</code> if the library successfully closes.<br>Returns <code>btLibErrNotOpen</code> if the referenced Bluetooth library was not open.                                                                                                                                                                                                                                           |
| <b>Comments</b>    | Applications must call this function when they no longer need the Bluetooth library. If the Bluetooth library open count is one, this function closes existing connections, saves the current accessibility mode, sets the accessible mode according to the preferences panel, and shuts down the library. If the Bluetooth library open count is greater than one, this function decrements the open count. |

### BtLibOpen Function

|                    |                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Open and initialize the Bluetooth library.                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | <code>Err BtLibOpen (UInt16 btLibRefNum,<br/>Boolean allowStackToFail)</code>                                                                                                                                                                                              |
| <b>Parameters</b>  | <code>→ btLibRefNum</code><br>Reference number for the Bluetooth library.<br><code>→ allowStackToFail</code><br>If true, opens the library even if the stack or radio fails to initialize. Otherwise, does not open the library if the stack or radio fails to initialize. |
| <b>Returns</b>     | Returns one of the following values:<br><code>btLibErrNoError</code><br>Success.                                                                                                                                                                                           |

`btLibErrAlreadyOpen`

This status code is not really an error. It is returned if the library was already open. In this case, the open count is incremented.

`btLibErrInUseByService`

The library is currently in use by a Bluetooth service.

`btLibErrOutOfMemory`

Not enough memory available to open the library.

`btLibErrRadioInitFailed`

The Bluetooth stack or radio could not be initialized. If `allowStackToFail` is true, the library still opens after this error occurs.

Applications must call this function before using the Bluetooth library. If the Bluetooth library is not already open, `BtLibOpen` opens the library, initializes it, and starts up the protocol stack component of the library. Otherwise it increments its open count.

The `allowStackToFail` parameter allows the library to be opened even if the Bluetooth stack or radio fails to initialize. It is useful for applications that only want to use the Bluetooth library's utility functions but not the radio. However, any application that needs to communicate with the radio must set `allowStackToFail` to false.

This function generates three events: a

[`btLibManagementEventRadioState`](#) event with a status of `btLibErrRadioInitialized`, a

[`btLibManagementEventLocalNameChange`](#) event indicating the local name of the device, and a

[`btLibManagementEventAccessibilityChange`](#) event indicating the accessibility of the device.

## Management Functions

The management functions handle the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. These functions perform tasks that include discovering devices, working with Asynchronous Connectionless

## Bluetooth Library: Management

### *BtLibCancelInquiry*

---

(ACL) links and piconets, and maintaining global settings for the Bluetooth library.

| <b>Purpose</b>     | Discover all available devices, present them in the user interface, and allow the user to select one or more of these devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Prototype</b>   | <pre>Err BtLibDiscoverMultipleDevices     (UInt16 btLibRefNum, Char *instructionTxt,      Char *buttonTxt,      BtLibClassOfDeviceType *deviceFilterList,      UInt8 deviceFilterListLen,      UInt8 *numDevicesSelected,      Boolean addressAsName, Boolean showLastList)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <ul style="list-style-type: none"><li>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</li><li>→ <i>instructionTxt</i><br/>Text displayed at the top of the selection box. Pass NULL to display the default text. The default text is "Select one or more devices:"</li><li>→ <i>buttonTxt</i><br/>Text for the OK button. Pass NULL to display the default text. The default button text is "OK"</li><li>→ <i>deviceFilterList</i><br/>Array of <a href="#">BtLibClassOfDeviceTypes</a>. This function presents to the user only the remote devices whose class matches a class in this list. If deviceFilterList is NULL, this function presents to the user all discovered devices.</li><li>→ <i>deviceFilterListLen</i><br/>Number of elements in deviceFilterList.</li><li>← <i>numDevicesSelected</i><br/>Number of selected devices. To obtain the actual device list, use the BtLibGetSelectedDevices function.</li><li>→ <i>addressAsName</i><br/>If true, display the Bluetooth addresses of the remote devices instead of their names. This option is available for debugging purposes.</li></ul> |

## Bluetooth Library: Management

### *BtLibDiscoverMultipleDevices*

---

→ *showLastList*

If true, causes all other parameters to be ignored and displays the same list as the previous call to `BtLibDiscoverMultipleDevices`.

**Returns** Returns one of the following values:

`btLibErrNoError`

Success

`btLibErrCanceled`

User canceled discovery.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This blocking call performs a full discovery for an application, including name and feature retrieval and testing. This function takes over the UI and presents a choice box to the user, allowing the user to select multiple devices from the list of devices that were discovered. This function does not return until the user chooses one or more devices, or cancels.

Setting the `showLastList` parameter to `true` allows you to present to the user the list of devices displayed in the previous call to `BtLibDiscoverMultipleDevices` or [`BtLibDiscoverSingleDevice\(\)`](#). This feature can be useful because a full discovery process takes approximately ten seconds. The cached device list remains valid even after you close the library, allowing other Bluetooth applications to use it.

Note that [`BtLibStartInquiry\(\)`](#) overwrites the cached device list. If you are using the `showLastList` feature, you should avoid calling `BtLibStartInquiry` between calls to `BtLibDiscoverMultipleDevices` or `BtLibDiscoverSingleDevice`.

Use [`BtLibGetSelectedDevices\(\)`](#) to retrieve the list of devices that the user selected.

| <b>Purpose</b>     | Discover all available devices, present them in the user interface, and allow the user to select one of these devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <pre>Err BtLibDiscoverSingleDevice     (UInt16 btLibRefNum, Char *instructionTxt,      BtLibClassOfDeviceType *deviceFilterList,      UInt8 deviceFilterListLen,      BtLibDeviceAddressType *selectedDeviceP,      Boolean addressAsName, Boolean showLastList)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>instructionTxt</i><br/>Text displayed at the top of the selection box. Pass NULL to display the default text. The default text is "Select a device:"</p> <p>→ <i>deviceFilterList</i><br/>Array of <a href="#">BtLibClassOfDeviceTypes</a>. This function displays only the remote devices whose class matches a class in this list. If deviceFilterList is NULL, this function displays all discovered devices.</p> <p>→ <i>deviceFilterListLen</i><br/>Number of elements in deviceFilterList.</p> <p>← <i>selectedDeviceP</i><br/>Pointer to a <a href="#">BtLibDeviceAddressType</a> where this function stores the address of the device the user selects. You need to allocate this space before calling this function.</p> <p>→ <i>addressAsName</i><br/>If true, display the Bluetooth addresses of the remote devices instead of their names. This option is available for debugging purposes.</p> <p>→ <i>showLastList</i><br/>If true, causes all other parameters to be ignored and displays the same list as the previous call to BtLibDiscoverSingleDevice.</p> |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <pre>btLibErrNoError     Success</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Bluetooth Library: Management

### *BtLibDiscoverSingleDevice*

---

`btLibErrCanceled`

User canceled the discovery.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

This blocking call performs a full discovery for an application, including name and feature retrieval and testing. This function takes over the UI and presents a choice box to the user, allowing the user to select a device from the list of devices that were discovered. This function does not return until the user chooses a device or cancels.

Setting the `showLastList` parameter to `true` allows you to present to the user the list of devices displayed in the previous call to `BtLibDiscoverSingleDevice` or [`BtLibDiscoverMultipleDevices\(\)`](#). This feature can be useful because a full discovery process takes approximately ten seconds. The cached device list remains valid even after you close the library, allowing other Bluetooth applications to use it.

Note that [`BtLibStartInquiry\(\)`](#) overwrites the cached device list. If you are using the `showLastList` feature, you should avoid calling `BtLibStartInquiry` between calls to `BtLibDiscoverSingleDevice` or `BtLibDiscoverMultipleDevices`.

| <b>Comments</b>    | Specify the preference with a member of the <code>BtLibGeneralPreferenceEnum</code> .                                                                                                                                                                                                                                                                                                                                                                                         |

### **BtLibGeneralPreferenceEnum**

The `BtLibGeneralPreferenceEnum` enum specifies the general preferences that can be accessed using the

## Bluetooth Library: Management

### *BtLibGetGeneralPreference*

---

[BtLibSetGeneralPreference\(\)](#) and  
[BtLibGetGeneralPreference\(\)](#) functions.

**Prototype**    typedef enum {  
                  btLibPref\_Name,  
                  btLibPref\_UnconnectedAccessible,  
                  btLibPref\_CurrentAccessible,  
                  btLibPref\_LocalClassOfDevice,  
                  btLibPref\_LocalDeviceAddress  
              } BtLibGeneralPrefEnum;

#### ***Value Descriptions***

btLibPref\_CurrentAccessible

This preference is a [BtLibAccessibleModeEnum](#) indicating the current accessibility mode of the local device.

btLibPref\_LocalClassOfDevice

This preference is a [BtLibClassOfDeviceType](#) indicating the class of the local device. You should never set this preference.

btLibPref\_Name

This preference is a [BtLibFriendlyNameType](#) containing the user-friendly name of the local device. If you retrieve this preference, you also need to allocate a buffer and set the [BtLibFriendlyNameType](#)'s name and nameLength fields to the buffer pointer and buffer length, respectively.

You should never set this preference.

btLibPref\_UnconnectedAccessible

This preference is a [BtLibAccessibleModeEnum](#) indicating the accessibility mode of the local device when it is unconnected. You should never set this preference.

| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>remoteDeviceP</i><br/>Pointer to a <a href="#">BtLibDeviceAddressType</a> containing the address of the device whose name is desired.</p> <p>↔ <i>nameP</i><br/>Pointer to a <a href="#">BtLibFriendlyNameType</a> structure in which to store the results of the lookup. You must allocate this structure and the name buffer it points to. You also must specify the size of the buffer in the <code>nameLength</code> field of the structure. When the function returns, ignore the <code>nameLength</code> field and use <code>StrLen</code> to obtain the actual length of the name. This parameter must not be NULL.</p> <p>→ <i>retrievalMethod</i><br/>Method used to retrieve the user-friendly remote device name. See <a href="#">BtLibGetNameEnum</a>.</p> |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>The name structure was successfully retrieved from the cache. No notification event will be generated.</p> <p><code>btLibErrBusy</code><br/>There is already a name request pending.</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrPending</code><br/>The results will be returned through a notification.</p> <p><code>btLibErrStackNotOpen</code><br/>The Bluetooth stack failed to initialize when the library was opened.</p>                                                                                                                                                                                                                                                                             |

## Bluetooth Library: Management

### *BtLibGetRemoteDeviceName*

---

**Comments** The Bluetooth library maintains a cache of 50 device names. If the `retrievalMethod` parameter is `btLibCachedThenRemote`, this function first checks the cache for a name. If the name is in the cache, the value is returned immediately in the `nameP` parameter. If the name is not in the cache, the function queries the remote device for its name, forming a temporary ACL connection if one is not already in place. In this case, the function returns `btLibErrPending` and generates a [`btLibManagementEventNameResult`](#) event when the name is available.

Other values of the `retrievalMethod` parameter can instruct this function to look for the name only in the cache or only on the remote device. See [`BtLibGetNameEnum`](#) for more information.

#### **BtLibGetNameEnum**

The `BtLibGetNameEnum` enum specifies whether to retrieve a device name from the cache, the remote device, or both.

**Prototype**

```
typedef enum {  
    btLibCachedThenRemote,  
    btLibCachedOnly,  
    btLibRemoteOnly  
} BtLibGetNameEnum;
```

#### ***Value Descriptions***

`btLibCachedOnly`

Look for a name in the cache. If the name is not in the cache, fail.

`btLibCachedThenRemote`

Look for a name in the cache. If the name is not in the cache, ask the remote device.

`btLibRemoteOnly`

Ignore any cached names and ask the remote device for its name.

## BtLibGetSelectedDevices Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## BtLibLinkConnect Function

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create a Bluetooth Asynchronous Connectionless (ACL) link.                            |
| <b>Declared In</b> | BtLib.h                                                                               |
| <b>Prototype</b>   | Err BtLibLinkConnect (UInt16 btLibRefNum,<br>BtLibDeviceAddressTypePtr remoteDeviceP) |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p>           |

## Bluetooth Library: Management

### *BtLibLinkConnect*

---

→ *remoteDeviceP*

Pointer to the a [BtLibDeviceAddressType](#) containing the address of the remote device.

**Returns** Returns one of the following values:

*btLibErrPending*

The results will be returned through a callback event.

*btLibErrAlreadyConnected*

The device is already in a pre-existing connection and cannot create a new connection.

*btLibErrBluetoothOff*

The Bluetooth radio is off. The user can turn the radio on and off with a setting in the preferences panel.

*btLibErrBusy*

A piconet is currently being created or destroyed.

*btLibErrNotOpen*

The referenced Bluetooth library is not open.

*btLibErrStackNotOpen*

The Bluetooth stack failed to initialize when the library was opened.

*btLibErrTooMany*

Cannot create another ACL link because the maximum allowed number has already been reached.

**Comments** An ACL link is a packet-switched physical level connection between two devices that is needed before the devices can form a RFCOMM or L2CAP connection.

When the connection is established or if it fails to be established, the [btLibManagementEventAclConnectOutbound](#) event is generated.

**Comments** See the [BtLibLinkSetState\(\)](#) function description for a list of the link states preferences.

**See Also** [BtLibLinkSetState\(\)](#)

## BtLibLinkSetState Function

**Purpose** Set the state of an ACL link

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibLinkSetState (UInt16 btLibRefNum,  
    BtLibDeviceAddressTypePtr remoteDeviceP,  
    BtLibLinkPrefsEnum pref, void *linkState,  
    UInt16 linkStateSize)
```

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *remoteDeviceP*  
The address of the remote device. This address identifies the ACL link.
- *pref*  
Link preference to set. See [BtLibLinkPrefsEnum](#).
- *linkState*  
Pointer to the value of the preference. This parameter must not be NULL. See [BtLibLinkPrefsEnum](#).
- *linkStateSize*  
Size, in bytes, of the linkState value.

**Returns** Returns one of the following values:

`btLibErrPending`  
The results will be returned through a callback event.

`btLibErrFailed`  
An attempt was made to encrypt a link before authenticating it.

`btLibErrNoAclLink`  
No link to the specified remote device exists.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

## Bluetooth Library: Management

### *BtLibLinkSetState*

---

`btLibErrParamError`

The preference cannot be set or `linkStateSize` is invalid.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** Applications use this function to set the state of an ACL link. This function may generate events depending on the preference you change. The [btLibManagementEventAuthenticationComplete](#) event indicates the link authentication has completed. The [btLibManagementEventEncryptionChange](#) indicates that the encryption has been enabled or disabled.

#### **BtLibLinkPrefsEnum**

The `BtLibLinkPrefsEnum` enum specifies the link state preferences that can be accessed with the [BtLibLinkSetState\(\)](#) and [BtLibLinkGetState\(\)](#) functions.

**Prototype**

```
typedef enum {  
    btLibLinkPref_Authenticated,  
    btLibLinkPref_Encrypted,  
    btLibLinkPref_LinkRole  
} BtLibLinkPrefsEnum;
```

#### **Value Descriptions**

`btLibLinkPref_Authenticated`

This preference is a Boolean and indicates whether the link has been authenticated or not.

`btLibLinkPref_Encrypted`

This preference is a Boolean and indicates whether the link is encrypted or not.

`btLibLinkPref_LinkRole`

This preference is a [BtLibConnectionRoleEnum](#) and indicates whether the remote device is a master or a slave. You cannot set this preference but you can get its value.

**See Also** [BtLibLinkGetState\(\)](#)

## BtLibPiconetCreate Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create a piconet or reconfigure an existing piconet so the local device is the master.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | <code>Err BtLibPiconetCreate (UInt16 btLibRefNum,<br/>Boolean unlockInbound, Boolean discoverable)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>unlockInbound</i><br/>If true, the piconet accepts inbound connections. Otherwise, the piconet only allows outbound connections.</p> <p>→ <i>discoverable</i><br/>If true, configures the radio to be discoverable. In other words, the radio responds to inquiries. If false, configures the radio to be only connectable. In other words, only devices that know the radio's Bluetooth device address can connect to it. This parameter is ignored if <i>unlockInbound</i> is false.</p>                                                                                                    |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>Successfully created the piconet with the local device as the master. No callback event is generated.</p> <p><code>btLibErrPending</code><br/>An existing ACL link needs to switch roles before this operation can complete.</p> <p><code>btLibErrFailed</code><br/>A piconet already exists.</p> <p><code>btLibErrInProgress</code><br/>Another piconet is currently being created.</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrStackNotOpen</code><br/>The Bluetooth stack failed to initialize when the library was opened.</p> |
| <b>Comments</b>    | If the accessibility of the radio changes due to this operation, a <a href="#"><code>btLibManagementEventAccessibilityChange</code></a> event is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Bluetooth Library: Management

### *BtLibPiconetDestroy*

---

generated. When the piconet is created, or if the piconet fails to be created, a [btLibManagementEventPiconetCreated](#) event is generated. The status field of the [BtLibManagementEventType](#) structure accompanying the event indicates whether the piconet was created or not.

**See Also** [BtLibPiconetDestroy\(\)](#), [BtLibPiconetUnlockInbound\(\)](#), [BtLibPiconetLockInbound\(\)](#)

## BtLibPiconetDestroy Function

**Purpose** Destroy the piconet by disconnecting links to all devices and removing all restrictions on whether the local device is a master or a slave.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibPiconetDestroy (UInt16 btLibRefNum)`

**Parameters** `→ btLibRefNum`  
Reference number for the Bluetooth library.

**Returns** Returns one of the following values:

`btLibErrNoError`  
Successfully destroyed the piconet. A [btLibManagementEventPiconetDestroyed](#) event is not generated.

`btLibErrPending`  
The piconet is being destroyed, and a [btLibManagementEventPiconetDestroyed](#) event will be generated when the operation succeeds or fails.

`btLibErrBusy`  
The piconet is already in the process of being destroyed.

`btLibErrNoPiconet`  
No piconet exists to be destroyed.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** A [btLibManagementEventAcldisconnect](#) event is generated for each ACL link that is disconnected. When the piconet is successfully destroyed or fails to be destroyed, a [btLibManagementEventPiconetDestroyed](#) is generated. The status field of the [BtLibManagementEventType](#) structure accompanying the event indicates whether the piconet was destroyed or not.

**See Also** [BtLibPiconetCreate\(\)](#)

## BtLibPiconetLockInbound Function

**Purpose** Prevent remote devices from creating ACL links into the piconet.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibPiconetLockInbound (UInt16 btLibRefNum)`

**Parameters** `→ btLibRefNum`  
Reference number for the Bluetooth library.

**Returns** Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrBusy`  
The piconet is in the process of being destroyed.
- `btLibErrNoPiconet`  
No piconet exists.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** After locking inbound connections, outbound connections are still allowed. Locking inbound connections maximizes the bandwidth for members of the piconet to transmit data to each other.

**See Also** [BtLibPiconetUnlockInbound\(\)](#)

## BtLibPiconetUnlockInbound Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Allow remote devices to create ACL links into the piconet.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>Err BtLibPiconetUnlockInbound     (UInt16 btLibRefNum, Boolean discoverable)</pre>                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>discoverable</i><br/>If true, configures the radio to be discoverable. In other words, the radio responds to inquiries. If false, configures the radio to be only connectable. In other words, only devices that know the radio's Bluetooth device address can connect to it.</p>                                                                                     |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>Success.</p> <p><code>btLibErrBusy</code><br/>The piconet is in the process of being destroyed.</p> <p><code>btLibErrNoPiconet</code><br/>No piconet exists.</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrStackNotOpen</code><br/>The Bluetooth stack failed to initialize when the library was opened.</p> |
| <b>Comments</b>    | Allowing inbound connections lowers the bandwidth available to transmit data between members of the piconet because the radio must periodically scan for incoming links.                                                                                                                                                                                                                                                                                  |
| <b>See Also</b>    | <a href="#"><u><code>BtLibPiconetLockInbound()</code></u></a>                                                                                                                                                                                                                                                                                                                                                                                             |

## BtLibRegisterManagementNotification Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Register a callback function to process events generated by management functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>Err BtLibRegisterManagementNotification     (UInt16 btLibRefNum,      BtLibManagementProcPtr callbackP,      UInt32 refCon)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>callbackP</i><br/>Pointer to a callback procedure to register. This pointer must not be NULL. See <a href="#">BtLibManagementCallback()</a> for more information.</p> <p>→ <i>refCon</i><br/>Application-defined data to pass to the event handler.</p>                                                                                                                                                                                                                                                                                                                                              |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>Success.</p> <p><code>btLibErrAlreadyRegistered</code><br/>The callback has already been registered with the management entity.</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrParamError</code><br/>One or more parameters is invalid.</p> <p><code>btLibErrStackNotOpen</code><br/>The Bluetooth stack failed to initialize when the library was opened.</p> <p><code>btLibErrTooMany</code><br/>There is no space available to store the callback. The management entity allows a maximum of 16 callbacks to be registered at a time.</p> |

## Bluetooth Library: Management

### *BtLibSetGeneralPreference*

---

**Comments** The management functions are asynchronous. That is, they return immediately and generate events when the task actually completes at a later time. To handle these events, you need to define a callback function with the same prototype as [BtLibManagementCallback\(\)](#). Then you need to register your callback function using `BtLibRegisterManagementNotification`. For examples of the callback events your callback function needs to handle, see the [Management Callback Events](#) section.

Applications should unregister their management callbacks before closing the Bluetooth library to prevent the callback table from overflowing. The callback table holds a maximum of 16 entries.

**See Also** [BtLibUnregisterManagementNotification\(\)](#)

## BtLibSetGeneralPreference Function

**Purpose** Set one of the general management preferences.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSetGeneralPreference
    (UInt16 btLibRefNum,
     BtLibGeneralPrefEnum pref, void *prefValue,
     UInt16 prefValueSize)
```

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *pref*  
General preference to set. See [BtLibGeneralPreferenceEnum](#).
- *prefValue*  
Pointer to the value of the preference. This parameter must not be NULL. See [BtLibGeneralPreferenceEnum](#).
- *prefValueSize*  
Size, in bytes, of *prefValue*.

**Returns** Returns one of the following values:

- `btLibErrNoError`  
Success.

`btLibErrPending`

The results will be returned through a notification.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrParamError`

One or more parameters is invalid. Be sure that `prefValueSize` matches the size of the preference value.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** See the [BtLibGetGeneralPreference\(\)](#) function description for a list of the preferences.

This function may generate events depending on the preference you change. The [btLibManagementEventAccessibilityChange](#) event indicates that the accessibility of the local device has changed.

**See Also** [BtLibGetGeneralPreference\(\)](#)

## BtLibStartInquiry Function

**Purpose** Start a Bluetooth inquiry.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibStartInquiry (UInt16 btLibRefNum,  
                          UInt8 timeout, UInt8 maxResp)`

**Parameters** → *btLibRefNum*

Reference number for the Bluetooth library.

→ *timeout*

Time, in seconds, this inquiry is allowed to take. If the inquiry does not complete within this time, it is canceled. The actual time is rounded to the nearest multiple of 1.28 seconds. If you specify a timeout period larger than 60 seconds, this function acts as if you specified a timeout period of 60 seconds. If this parameter is 0, the timeout period defaults to 10.24 seconds as specified in the Generic Access Profile.

→ *maxResp*

Maximum number of responses the inquiry accepts. Responses are not guaranteed to be unique.

## Bluetooth Library: Management

### *BtLibStartInquiry*

---

**Returns** Returns one of the following values:

`btLibErrPending`

The results will be returned through callback events.

`btLibErrBluetoothOff`

The Bluetooth radio is off. The user can turn the radio on and off with a setting in the preferences panel.

`btLibErrInProgress`

Another inquiry is already in progress.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** The function performs a low-level Bluetooth inquiry, as opposed to a full device discovery. Specifically, inquiries started with this function only return the Bluetooth address and the class of the discovered device. This function does not have a user interface.

Every time a device is discovered, a [`btLibManagementEventInquiryResult`](#) callback event is generated. When the inquiry is complete, a [`btLibManagementEventInquiryComplete`](#) callback event is generated. If the application calls [`BtLibCancelInquiry\(\)`](#), a [`btLibManagementEventInquiryCanceled`](#) callback event is generated.

**See Also** [`BtLibCancelInquiry\(\)`](#)

## **BtLibUnregisterManagementNotification Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Unregister a previously registered management callback.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <pre>Err BtLibUnregisterManagementNotification     (UInt16 btLibRefNum,      BtLibManagementProcPtr callbackP)</pre>                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>callbackP</i><br/>Pointer to the callback procedure to unregister. This pointer must not be NULL.</p>                                                                                                                                                                                                                                                                                                       |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>Success.</p> <p><code>btLibErrError</code><br/>The callback referenced by <i>callbackP</i> has not been registered.</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrParamError</code><br/>One or more parameters are invalid.</p> <p><code>btLibErrStackNotOpen</code><br/>The Bluetooth stack failed to initialize when the library was opened.</p> |
| <b>Comments</b>    | Applications should unregister their management callbacks before closing the library to prevent the callback table from overflowing. The callback table holds a maximum of 16 entries.                                                                                                                                                                                                                                                                                                          |
| <b>See Also</b>    | <a href="#"><u><code>BtLibRegisterManagementNotification()</code></u></a>                                                                                                                                                                                                                                                                                                                                                                                                                       |

## **Application-Defined Functions**

This section describes the callback functions that handle management events. These functions are supplied by the developer and can be named anything.

## BtLibManagementCallback Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Signal the result of a Bluetooth management event. When the event takes place, this callback function is called.                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | <code>BtLibTypes.h</code>                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>void (*BtLibManagementProcPtr)     (BtLibManagementEventType *mEvent,      UInt32 refCon)</pre>                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>mEvent</i></p> <p><a href="#">BtLibManagementEventType</a> structure containing the event parameters.</p> <p>→ <i>refCon</i></p> <p>General purpose integer which you can use to hold application-specific information. When you register the callback with the <a href="#">BtLibRegisterManagementNotification()</a> function, you can specify a value to pass to this parameter.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Comments</b>    | <p>The event and status of the event are in the <i>mEvent</i> structure. See <a href="#">Management Callback Events</a> for more information.</p> <p>You must register this function using the <a href="#">BtLibRegisterManagementNotification()</a> function before it starts receiving events.</p>                                                                                           |

# Bluetooth Library: Sockets and Service Discovery

---

The Bluetooth library uses sockets to represent L2CAP, RFCOMM, and SDP connections. This chapter presents reference material for the socket and SDP support provided by the Bluetooth library API:

## [Socket-Related Data Structures](#)

This section lists some of the more important types used by the Bluetooth library.

## [Socket Callback Events](#)

The Bluetooth library socket API supports L2CAP, RFCOMM, and SDP, the upper protocols of the Bluetooth specification. As with the management functions, the socket functions are mostly asynchronous. To signal to the application that socket operations have completed, the Bluetooth library generates *socket callback events* by calling a callback function.

## [Socket Disconnection Error Codes](#)

In addition to the standard error codes that can accompany socket events, the status codes accompanying the disconnection and connection events can have the additional values enumerated in this section.

## [Socket Functions](#)

The functions in this section perform general socket tasks and tasks related to L2CAP and RFCOMM sockets. The functions specific to SDP sockets are in the next section.

## [Service Discovery Protocol Functions](#)

This section describes functions and macros specific to the Bluetooth Service Discovery Protocol (SDP).

#### [Application-Defined Functions](#)

This section describes the callback functions that handle socket events.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Socket-Related Data Structures

This section lists some of the more important types used by the Bluetooth library.

### **BtLibL2CapPsmType Typedef**

**Purpose** The `BtLibL2CapPsmType` type represents a Protocol and Server Multiplexer (PSM) value. See the “Logical Link and Adaptation Protocol Specification” chapter of the *Specification of the Bluetooth System* for more information about PSM values. The Bluetooth library only supports two-byte PSM values.

**Prototype** `typedef UInt16 BtLibL2CapPsmType;`

### **BtLibLanguageBaseTripletType Struct**

**Purpose** The `BtLibLanguageBaseTripletType` structure represents a language base attribute identifier list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information.

**Prototype**

```
typedef struct BtLibLanguageBaseTripletType {
    UInt16 naturalLanguageIdentifier;
    UInt16 characterEncoding;
    UInt16 baseAttributeID;
} BtLibLanguageBaseTripletType;
```

### Field Descriptions

naturalLanguageIdentifier

A UInt16 representing a natural language. See [Language Constants](#) for a set of constants that can be used in this field.

characterEncoding

A UInt16 representing a character set encoding. See [Character Encoding Constants](#) for a set of constants that can be used in this field.

baseAttributeID

Base attribute identifiers for attributes represented in this language. See [Attribute Identifier Offsets](#) for offsets that are added to this value to get the attribute identifiers for specific attributes represented in this language.

### Language Constants

These constants are used in the naturalLanguageIdentifier field of the BtLibLanguageBaseTripletType and are defined in the ISO 639:1988 specification.

### Character Encoding Constants

These constants are used to specify the character encoding used for SDP attributes. More information about these character sets can be found at <http://www.iana.org/assignments/character-sets>.

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Attribute Identifier Offsets

#### Constants

btLibServiceNameOffset

The offset from the baseAttributeID to get the attribute identifier of the service name.

`btLibServiceDescriptionOffset`

The offset from the `baseAttributeID` to get the attribute identifier of the service description.

`btLibProviderNameOffset`

The offset from the `baseAttributeID` to get the attribute identifier of the provider name.

## BtLibProfileDescriptorListEntryType Struct

**Purpose** The `BtLibProfileDescriptorListEntryType` structure represents an entry in a profile descriptor list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information about profile descriptor list attributes.

**Prototype**

```
typedef struct
    BtLibProfileDescriptorListEntryType {

        BtLibSdpUuidType profUUID;
        UInt16 version;
    } BtLibProfileDescriptorListEntryType;
```

### Field Descriptions

`profUUID`

The UUID of the profile.

`version`

The version of the profile.

## BtLibProtocolDescriptorListEntryType Struct

**Purpose** The `BtLibProtocolDescriptorListEntryType` structure represents an entry in a protocol descriptor list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information.

**Prototype**

```
typedef struct
    BtLibProtocolDescriptorListEntryType {

        BtLibSdpUuidType protoUUID;
```

## Bluetooth Library: Sockets and Service Discovery

### *BtLibRfCommServerIdType*

---

```
union {  
    BtLibL2CapPsmType psm;  
    BtLibRfCommServerIdType channel;  
} param;  
} BtLibProtocolDescriptorListEntryType;
```

#### Field Descriptions

protoUUID

The UUID of the protocol.

param

A union containing two members: psm and channel. psm is applicable for a L2CAP protocol descriptor and specifies the Protocol and Service Multiplexor. channel is applicable to a RFCOMM protocol descriptor and specifies the server channel.

### **BtLibRfCommServerIdType Typedef**

**Purpose** The `BtLibRfCommServerIdType` type represents a RFCOMM server channel. See the “RFCOMM with TS 07.10” chapter of the *Specification of the Bluetooth System* for more information about server channels.

**Prototype** `typedef UInt8 BtLibRfCommServerIdType;`

### **BtLibSdpAttributeDataType Struct**

**Purpose** The `BtLibSdpAttributeDataType` union is used to encapsulate an SDP attribute or a list entry in an SDP attribute. The [`BtLibSdpServiceRecordGetAttribute\(\)`](#) function gets an attribute or a list entry and return its contents in a `BtLibSdpAttributeDataType`. The [`BtLibSdpServiceRecordSetAttribute`](#) function sets an attribute or list entry according to the contents of a `BtLibSdpAttributeDataType`. This type supports the universal attributes defined in the *Specification of the Bluetooth System*.

**Prototype** `typedef union BtLibSdpAttributeDataType {  
 BtLibSdpUuidType serviceClassUuid;`

```
UInt32 serviceRecordState;
BtLibSdpUuidType serviceIdUuid;
BtLibProtocolDescriptorListEntryType
    protocolDescriptorListEntry;
BtLibSdpUuidType browseGroupUuid;
BtLibLanguageBaseTripletType
    languageBaseTripletListEntry;
UInt32 timeToLive;
UInt8 availability;
BtLibProfileDescriptorListEntryType
    profileDescriptorListEntry;
BtLibUrlType documentationUrl;
BtLibUrlType clientExecutableUrl;
BtLibUrlType iconUrl;
BtLibStringType serviceName;
BtLibStringType providerName;
} BtLibSdpAttributeDataType;
```

Note that if you're retrieving a string or a URL using the [BtLibSdpServiceRecordGetAttribute\(\)](#) function, you first need to allocate a buffer in addition to this union. This buffer must be large enough to contain the anticipated size of the string or URL. You must also initialize the string pointer and string length fields of the appropriate `BtLibAttributeDataType` union member. For example, if you're retrieving an icon URL, you need to set `iconURL.url` to point to the buffer. You also need to set `iconURL.urllen` to the length of the buffer.

**See Also** [BtLibSdpUuidType](#),  
[BtLibProtocolDescriptorListEntryType](#),  
[BtLibProfileDescriptorListEntryType](#),  
[BtLibLanguageBaseTripletType](#), [BtLibUrlType](#),  
[BtLibStringType](#)

## BtLibSdpAttributeIdType Typedef

**Purpose** The `BtLibSdpAttributeIdType` type represents a SDP attribute identifier.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpAttributeIdType*

---

**Prototype**    `typedef UInt16 BtLibSdpAttributeIdType;`

The following constants are defined by the Bluetooth library. They represent the universal attributes in the *Specification of the Bluetooth System*.

#### **Universal Attribute IDs**

**Constants**    `btLibServiceClassIdList`  
                 `btLibServiceRecordState`  
                 `btLibServiceId`  
                 `btLibProtocolDescriptorList`  
                 `btLibBrowseGroupList`  
                 `btLibLanguageBaseAttributeIdList`  
                 `btLibTimeToLive`  
                 `btLibAvailability`  
                 `btLibProfileDescriptorList`  
                 `btLibDocumentationUrl`  
                 `btLibClientExecutableUrl`  
                 `btLibIconUrl`

## BtLibSdpRecordHandle Typedef

**Purpose** The BtLibSdpRecordHandle type, also called an *SDP memory handle*, provides a memory handle to an *SDP memory record*.

**Prototype**

```
typedef MemHandle BtLibSdpRecordHandle;
```

A SDP memory record can have two roles: it can contain a local SDP service record or it can refer to an SDP service record on a remote device. In the latter role, the SDP memory record is said to be *mapped* to a service record on the remote device. The [BtLibSdpServiceRecordMapRemote\(\)](#) function performs this mapping.

## BtLibSdpRemoteServiceRecordHandle Typedef

**Purpose** The BtLibSdpRemoteServiceRecordHandle type represents a SDP service record handle on a remote device as defined in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*. The documentation refers to this type as a *remote service record handle*.

**Prototype**

```
typedef UInt32 BtLibSdpRemoteServiceRecordHandle;
```

Note that this type is different from the [BtLibSdpRecordHandle](#) type, which refers to a memory chunk containing an SDP service record.

## BtLibSdpUuidSizeEnum Enum

**Purpose** The BtLibSdpUuidSizeEnum enum specifies the sizes that a UUID can have. See [BtLibSdpUuidType](#) for more information.

**Prototype**

```
typedef enum {  
    btLibUuidSize16 = 2,  
    btLibUuidSize32 = 4,  
    btLibUuidSize128 = 16  
} BtLibSdpUuidSizeEnum;
```

### Value Descriptions

btLibUuidSize16  
16-bit UUID

`btLibUuidSize32`

32-bit UUID

`btLibUuidSize128`

Full size 128-bit UUID

## BtLibSdpUuidType Struct

**Purpose** The `BtLibSdpUuidType` structure represents a Universally Unique Identifier (UUID). A UUID is a 128-bit value that is generated in a manner that guarantees that it is different from every other UUID.

The “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* reserves a set of UUIDs for common Bluetooth services and protocols. You can specify these with 32 bits—the remaining 96 bits have a fixed value. A subset of these can be specified with 16 bits zero-extended to 32 bits. Therefore you can specify a UUID using 16, 32, or 128 bits.

You generally don’t set this type directly. Instead, you use the [BtLibSdpUuidInitialize\(\)](#) macro.

**Prototype**

```
typedef struct BtLibSdpUuidType {  
    BtLibSdpUuidSizeEnum size;  
    UInt8 UUID[16];  
} BtLibSdpUuidType;
```

### Field Descriptions

`size`

The number of bits used to specify the UUID. See [BtLibSdpUuidSizeEnum](#).

`UUID`

The value of the UUID. If you’re setting the value of this field, use the [BtLibSdpUuidInitialize\(\)](#) macro.

### Predefined UUIDs

**Constants**

```
btLibSdpUUID_SC_SERVICE_DISCOVERY_SERVER  
btLibSdpUUID_SC_BROWSE_GROUP_DESC  
btLibSdpUUID_SC_PUBLIC_BROWSE_GROUP
```

```
btLibSdpUUID_SC_SERIAL_PORT

btLibSdpUUID_PROT_TCS_BIN
btLibSdpUUID_PROT_L2CAP
btLibSdpUUID_PROT_IP
btLibSdpUUID_PROT_UDP
btLibSdpUUID_PROT_TCP
btLibSdpUUID_PROT_TCS_AT
```

btLibSdpUUID\_PROT\_OBEX

btLibSdpUUID\_PROT\_FTP

btLibSdpUUID\_PROT\_HTTP

btLibSdpUUID\_PROT\_WSP

## BtLibSocketEventType Struct

**Purpose** The BtLibSocketEventType structure contains detailed information regarding a socket callback event. All socket events have some common data. Most socket events have additional data specific to those events. The specific data is stored in a union that is part of the BtLibSocketEvent data structure.

**Prototype**

```
typedef struct _BtLibSocketEventType {  
    BtLibSocketEventEnum event;  
    BtLibSocketRef socket;  
    Err status;  
    union  
    {  
        ...  
    } eventData;  
} BtLibSocketEventType,  
  *BtLibSocketEventTypePtr;
```

### Field Descriptions

event

BtLibSocketEventEnum enum member that indicates which socket event has occurred. See [Socket Callback Events](#).

socket

Socket associated with the event.

status

Status of the event. The [Socket Callback Events](#) section gives more details about how to interpret this field for specific events.

eventData

Data associated with the event. The member of this union that is valid depends on the event. See [Socket Callback Events](#) for more information.

## **BtLibSocketRef Typedef**

**Purpose** The BtLibSocketRef type identifies a socket.

**Prototype** `typedef Int16 BtLibSocketRef;`

## **BtLibStringType Struct**

**Purpose** The BtLibStringType structure represents a string in an SDP attribute.

**Prototype** `typedef struct BtLibStringType {  
 Char *str;  
 UInt16 strLen;  
} BtLibStringType;`

### **Field Descriptions**

`str`

An array of characters representing the string. This array is not null-terminated.

`strLen`

The length of the string.

## **BtLibUrlType Struct**

**Purpose** The BtLibUrlType structure represents a uniform resource locator in an SDP attribute.

**Prototype** `typedef struct BtLibUrlType {  
 Char *url;  
 UInt16 urlLen;  
} BtLibUrlType;`

### **Field Descriptions**

`url`

An array of characters representing the URL. This array is not null-terminated.

`urlLen`

The length of the string.

## Socket Callback Events

The Bluetooth library socket API supports L2CAP, RFCOMM, and SDP, the upper protocols of the Bluetooth specification. As with the management functions, the socket functions are mostly asynchronous. To signal to the application that socket operations have completed, the Bluetooth library generates a *socket callback events* by calling a callback function.

You specify the callback function when you create a socket. When an event occurs, the callback function is called with two parameters: a pointer to a [BtLibSocketEventType](#) structure and a pointer to a user-defined structure.

The [BtLibSocketEventType](#) structure contains an event field, which indicates the reason the callback is called, a status field, which indicates status information associated with the event, a socket field, which indicates the socket associated with the event, and a union of several structures. The member of the union that is valid depends on the event. The meaning of the events is described in the following sections.

### **btLibSocketEventConnectedInbound**

A remote connection has been accepted because the application has called [BtLibSocketRespondToConnection\(\)](#).

For this event, the eventData field contains the following field:

```
BtLibSocketRef newSocket;
```

This [BtLibSocketRef](#) contains the reference to the new socket.

If the remote device requests a L2CAP connection, this event is sent to the L2CAP listener socket with a PSM that matches the PSM of the requested connection. The Bluetooth library creates a new socket that exchanges data with the remote device.

If the remote device requests an RFCOMM connection, this event is sent to the RFCOMM listener socket with a server channel that matches the server channel of the requested connection. The Bluetooth library converts the listener socket into socket that exchanges data with the remote device.

## **btLibSocketEventConnectedOutbound**

An outbound connection initiated by a call to [BtLibSocketConnect\(\)](#) has completed. The status field is `btLibErrNoError` if the connection has completed successfully. Otherwise, the status field indicates why the connection failed.

## **btLibSocketEventConnectRequest**

A remote device has requested a connection.

You must respond to this event with a call to [BtLibSocketRespondToConnection\(\)](#).

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType requestingDevice;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device requesting the connection.

If the remote device requests a L2CAP connection, this event is sent to the L2CAP listener socket with a PSM that matches the PSM of the request.

If the remote device requests an RFCOMM connection, this event is sent to the RFCOMM listener socket with a server channel that matches the server channel of the request.

To convert a socket into a listener socket use the [BtLibSocketListen\(\)](#) function.

## **btLibSocketEventData**

**Purpose** Data has been received on a socket.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    UInt16 dataLen;  
    UInt8 *data;  
} data;
```

#### Value Descriptions

`dataLen`

The size, in bytes, of the received data.

`data`

A pointer to the received data.

#### **btLibSocketEventDisconnected**

The connection has been lost or one of the devices has disconnected. The socket is now invalid. The `status` field indicates the reason for the disconnection.

#### **btLibSocketEventSdpServiceRecordHandle**

**Purpose** A request for remote service records matching a list of service classes has completed. The application initiated this request by calling the [BtLibSdpServiceRecordsGetByServiceClass\(\)](#) function.

If the `status` field is `btLibErrNoError`, the SDP operation completed successfully, and the `eventData` field contains valid information. Otherwise the SDP operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {
    UInt16 numSrvRec;
    BtLibSdpRemoteServiceRecordHandle
        *serviceRecordList;
} sdpServiceRecordHandles;
```

#### Value Descriptions

`numSrvRec`

Number of remote service record handles in the returned array.

serviceRecordList

An array of [BtLibSdpRemoteServiceRecordHandles](#) for the service records matching the service class list.

### btLibSocketEventSdpGetAttribute

**Purpose** An attribute request has completed. The application initiated this request by calling the [BtLibSdpServiceRecordGetAttribute\(\)](#) function.

If the status field is `btLibErrNoError`, the operation completed successfully, and the `eventData` field contains valid data. Otherwise the operation failed, and the status field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    BtLibSdpAttributeIdType attributeID;  
    BtLibSdpRecordHandle recordH;  
    union {  
        ...  
    } info;  
} sdpAttribute;
```

#### Value Descriptions

attributeID

The attribute identifier of the attribute.

recordH

A handle identifying the SDP memory record from which the attribute is retrieved.

info

A union containing information specific to the event. See [The info Field](#).

#### The info Field

For this event, the `info` field contains the following structure:

**Prototype**

```
struct {  
    BtLibSdpAttributeDataType *attributeValues;
```

## Bluetooth Library: Sockets and Service Discovery

*btLibSocketEventSdpGetStringLen*

---

```
    UInt16 listNumber;  
    UInt16 listEntry;  
} data;
```

### Value Descriptions

attributeValues

A [BtLibSdpAttributeDataType](#) containing the value of the attribute or list entry.

listNumber

The index of the list in which this list entry appears or 0 if the attribute is not a protocol descriptor list. The index of the first list is 0.

listEntry

The index of the list entry within the list or 0 if the attribute is not a list. The index of the first entry is 0.

## btLibSocketEventSdpGetStringLen

### Purpose

A string or URL length request has completed. The application initiated this request by calling

[BtLibSdpServiceRecordGetStringOrUrlLength\(\)](#).

If the status field is `btLibErrNoError`, the operation completed successfully, and length can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

### Prototype

```
struct {  
    BtLibSdpAttributeIdType attributeID;  
    BtLibSdpRecordHandle recordH;  
    union {  
        ...  
    } info;  
} sdpAttribute;
```

#### Value Descriptions

`attributeID`

The attribute identifier of the attribute.

`recordH`

A handle identifying the SDP memory record from which the string length is retrieved.

`info`

A union containing information specific to the event. See [The info Field](#).

#### The info Field

For this event, the `info` field contains the following field:

`UInt16 strLength;`

This field contains the length of the string or URL represented by the attribute. Bluetooth strings and URLs are not null-terminated.

## btLibSocketEventSdpGetNumListEntries

#### Purpose

A number of list entries request has completed. The application initiated this request by calling

[`BtLibSdpServiceRecordGetNumListEntries\(\)`](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the number of list entries can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

#### Prototype

```
struct {  
    BtLibSdpAttributeIdType attributeID;  
    BtLibSdpRecordHandle recordH;  
    union {  
        ...  
    } info;  
} sdpAttribute;
```

#### Value Descriptions

`attributeID`

The attribute identifier of the attribute.

`recordH`

A handle identifying the SDP memory record from which the number of list entries is retrieved.

`info`

A union containing information specific to the event. See [The info Field](#).

#### The info Field

For this event, the `info` field contains the following field:

```
UInt16 numItems;
```

This field contains the number of entries in the list attribute.

## btLibSocketEventSdpGetNumLists

**Purpose** A number of lists request has completed. The application initiated this request by calling [BtLibSdpServiceRecordGetNumLists\(\)](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the number of lists can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

#### Value Descriptions

`attributeID`

The attribute identifier of the attribute.

`recordH`

A handle identifying the SDP memory record from which the number of lists is retrieved.

`info`

A union containing information specific to the event. See [The info Field](#).

#### The info Field

For this event, the `info` field contains the following field:

```
UInt16 numItems;
```

This field contains the number of lists in the protocol list descriptor attribute.

### btLibSocketEventSdpGetRawAttribute

**Purpose** A get raw attribute request has completed. The application initiated the request by calling [BtLibSdpServiceRecordGetRawAttribute\(\)](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the raw attribute can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

## Bluetooth Library: Sockets and Service Discovery

*btLibSocketEventSdpGetRawAttributeSize*

---

### Value Descriptions

attributeID

The attribute identifier of the attribute.

recordH

A handle identifying the SDP memory record from which the raw attribute is retrieved.

info

A union containing information specific to the event. See [The info Field](#).

### The info Field

For this event, the info field contains the following structure:

**Prototype**

```
struct {
    UInt16 valSize;
    UInt8 *value;
} rawData;
```

### Value Descriptions

valSize

Number of size, in bytes, of the raw attribute value.

value

Byte array containing the raw attribute value.

## btLibSocketEventSdpGetRawAttributeSize

**Purpose** A get raw attribute size request has completed. The application initiated this request by calling [BtLibSdpServiceRecordGetSizeOfRawAttribute\(\)](#).

If the status field is `btLibErrNoError`, the operation completed successfully, and the size of the attribute can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {
    BtLibSdpAttributeIdType attributeID;
```

```
BtLibSdpRecordHandle recordH;  
union {  
    ...  
} info;  
} sdpAttribute;
```

#### Value Descriptions

**attributeID**

The attribute identifier of the attribute.

**recordH**

A handle identifying the SDP memory record from which the size of the raw attribute is retrieved.

**info**

A union containing information specific to the event. See [The info Field](#).

#### The info Field

For this event, the info field contains the following field:

```
UInt16 valSize;
```

This field contains the size, in bytes, of the raw attribute value.

## btLibSocketEventSdpGetServerChannelBy Uuid

**Purpose** A get server channel request has completed. The application initiated this request by calling [BtLibSdpGetServerChannelByUuid\(\)](#).

If the status field is `btLibErrNoError`, the operation completed successfully, and the server channel can be found in the `eventData` field. Otherwise, the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    BtLibSdpRemoteServiceRecordHandle  
    remoteHandle;
```

## Bluetooth Library: Sockets and Service Discovery

*btLibSocketEventSdpGetPsmByUuid*

---

```
union {  
    ...  
} param;  
} sdpByUuid;
```

### Value Descriptions

`remoteHandle`

The handle for the remote SDP service record.

`param`

A union containing information that depends on the event.  
See [The param Field](#).

### The param Field

For this event, the param field contains the following field:

```
BtLibRfCommServerIdType channel;
```

This [BtLibRfCommServerIdType](#) contains the RFCOMM server channel represented by the SDP service record.

## btLibSocketEventSdpGetPsmByUuid

**Purpose** A get PSM request has completed. The application initiated this request by calling [BtLibSdpGetPSMByUuid\(\)](#).

If the status field is `btLibErrNoError`, the operation completed successfully, and the server channel can be found in the `eventData` field. Otherwise, the operation failed, and the status field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    BtLibSdpRemoteServiceRecordHandle  
        remoteHandle;  
    union {  
        ...  
    } param;  
} sdpByUuid;
```

#### Value Descriptions

`remoteHandle`

The handle for the remote SDP service record.

`param`

A union containing information that depends on the event.

See [The param Field](#).

#### The param Field

For this event, the `param` field contains the following field:

```
BtLibL2CapPsmType psm;
```

This [BtLibL2CapPsmType](#) contains the PSM value of the L2CAP channel represented by the SDP service record.

## btLibSocketEventSendComplete

**Purpose** A send request has completed. The application initiated this request by calling [BtLibSocketSend\(\)](#).

For this event, the `eventData` field contains the following structure:

**Prototype**

```
struct {  
    UInt16 dataLen;  
    UInt8 *data;  
} data;
```

#### Value Descriptions

`dataLen`

The number of bytes of data that were actually sent.

`data`

Not used. This variable does not contain any valid information.

#### Error Conditions

`btLibErrNoError`

Success.

`btLibErrNoAclLink`

No ACL Link.

## Socket Disconnection Error Codes

In addition to the standard error codes that can accompany socket events, the status codes accompanying the [`btLibSocketEventConnectedInbound`](#), [`btLibSocketEventConnectedOutbound`](#), and [`btLibSocketEventDisconnected`](#) events can have the following additional values:

`btLibL2DiscConfigOptions`  
Configuration failed due to an unrecognized configuration option.

`btLibL2DiscConfigReject`  
Configuration was rejected (unknown reason).

`btLibL2DiscConfigUnacceptable`  
Configuration failed due to unacceptable parameters.

`btLibL2DiscConnNoResources`  
The remote device is out of resources.

`btLibL2DiscConnPsmUnsupported`  
The remote device does not support the requested protocol service (PSM).

`btLibL2DiscConnSecurityBlock`  
The remote device's security system denied the connection.

`btLibL2DiscLinkDisc`  
The underlying ACL Link was disconnected.

`btLibL2DiscQosViolation`  
The connection was terminated due to a Quality of Service (QOS) violation.

`btLibL2DiscReasonUnknown`  
Disconnection occurred for an unknown reason.

`btLibL2DiscRequestTimeout`  
An L2CAP request timed out.

`btLibL2DiscSecurityBlock`  
The local security manager refused the connection attempt.

`btLibL2DiscUserRequest`  
Disconnection was requested by either the local or remote device.

## Socket Functions

The Bluetooth library uses sockets to represent L2CAP, RFCOMM, and SDP connections. The functions in this section perform general socket tasks and tasks related to L2CAP and RFCOMM sockets. The functions specific to SDP sockets are in the [Service Discovery Protocol Functions](#) section.

### BtLibSocketAdvanceCredit Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Advance credit to a given RFCOMM connection socket.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Err BtLibSocketAdvanceCredit (UInt16 btLibRefNum,<br/>BtLibSocketRef socket, UInt8 credit)</code>                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>socket</i><br/>RFCOMM socket reference number.</p> <p>→ <i>credit</i><br/>Number credits to add to the total number of credits for this socket. The total number of credits represents the number of packets the remote device can send before data flow stops.</p>                                                              |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrNoError</code><br/>Success</p> <p><code>btLibErrFailed</code><br/>Too many credits advanced.</p> <p><code>btLibErrSocket</code><br/>The specified socket is invalid.</p> <p><code>btLibErrSocketProtocol</code><br/>The specified socket is not an RFCOMM socket.</p> <p><code>btLibErrSocketRole</code><br/>The specified socket is not connected.</p> |
| <b>Comments</b>    | RFCOMM uses a credit based flow control mechanism. For each credit the connection has, one packet of data can be sent. When the                                                                                                                                                                                                                                                                                      |

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketClose*

---

credits are spent, data flow stops until you advance more credits using this function.

Multiple calls to this function have a cumulative effect.

### **BtLibSocketClose Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Close a socket, free associated resources, and kill all associated socket connections.                                                                                                                                                                                                                                                                             |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Err BtLibSocketClose (UInt16 btLibRefNum,<br/>    BtLibSocketRef socket)</pre>                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>socket</i><br/>Reference number of socket to close.</p>                                                                                                                                                                                                                        |
| <b>Returns</b>     | Returns one of the following values:<br><br><code>btLibErrNoError</code><br>Success.<br><br><code>btLibErrNotOpen</code><br>The referenced Bluetooth library is not open.<br><br><code>btLibErrSocket</code><br>The specified socket is invalid.<br><br><code>btLibErrStackNotOpen</code><br>The Bluetooth stack failed to initialize when the library was opened. |
| <b>Comments</b>    | No callback events are generated when closing a socket.                                                                                                                                                                                                                                                                                                            |

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketConnect*

---

[btLibSocketEventDisconnected](#) is generated. In both cases, the status field indicates the reason for the failure.

If the connection succeeds, the [btLibSocketEventData](#) event is generated whenever data is received from the remote device. When the channel disconnects, a [btLibSocketEventDisconnected](#) event is generated.

### **BtLibSocketConnectInfoType**

The `BtLibSocketConnectInfoType` structure allows you to specify the address of the remote device and data specific to the protocol of the socket. The protocol-specific data is stored as a union; the member of the union that is valid depends on the protocol.

**Prototype**

```
typedef struct BtLibSocketConnectInfoType {
    BtLibDeviceAddressTypePtr remoteDeviceP;
    union {
        ...
    } data;
} BtLibSocketConnectInfoType;
```

### **Field Description**

`remoteDeviceP`

A pointer to a [BtLibDeviceAddressType](#) that contains the address of the remote device.

`data`

A union containing protocol-specific information. This union has two members: [L2Cap](#), and [RfComm](#).

### **L2Cap**

Use the L2Cap union member if you're setting up a L2CAP socket. This member contains the following structure:

**Prototype**

```
struct {
    BtLibL2CapPsmType remotePsm;
    UInt16 minRemoteMtu;
    UInt16 localMtu;
} L2Cap;
```

### Field Descriptions

remotePsm

A [BtLibL2CapPsmType](#) representing the protocol and service multiplexer (PSM) identifier of the protocol to which this socket should connect. This identifier is obtained using the Service Discovery Protocol (SDP).

minRemoteMtu

The minimum MTU, or packet size, that your application can support.

localMtu

The MTU, or packet size, of the local device.

### **RfComm**

Use the RfComm union member if you're setting up a RFCOMM socket. This member contains the following structure:

### **Prototype**

```
struct {  
    BtLibRfCommServerIdType remoteService;  
    UInt16 maxFrameSize;  
    UInt8 advancedCredit;  
} RfComm;
```

### Field Descriptions

remoteService

A [BtLibRfCommServerIdType](#) representing the RFCOMM service channel on the remote device to which this socket should connect. This identifier is obtained using the Service Discovery Protocol (SDP).

maxFrameSize

The maximum frame size your application can handle. This value must be between BT\_RF\_MINFRAMESIZE and BT\_RF\_MAXFRAMESIZE. If your application can handle any frame size, set this value to BT\_RF\_DEFAULT\_FRAMESIZE.

advancedCredit

An amount of credit the socket advances to the remote device when it successfully connects. Additional credit can be

## Bluetooth Library: Sockets and Service Discovery

*BtLibSocketCreate*

---

advanced using the [BtLibSocketAdvanceCredit\(\)](#) function once the connection has been established.

**See Also**    [BtLibSocketSend\(\)](#), [BtLibSocketClose\(\)](#)

### BtLibSocketCreate Function

**Purpose**    Create a socket with foreground notification. The Bluetooth library supports a maximum of 16 socket connections.

**Declared In**    `BtLib.h`

**Prototype**    `Err BtLibSocketCreate (UInt16 btLibRefNum,  
                              BtLibSocketRef *socketRefP,  
                              BtLibSocketProcPtr callbackP, UInt32 refCon,  
                              BtLibProtocolEnum socketProtocol)`

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- ← *socketRefP*  
Pointer to an allocated [BtLibSocketRef](#) that contains the socket value upon return. This pointer must not be NULL.
- *callbackP*  
Callback procedure used to respond to socket events. This value must not be NULL.
- *refCon*  
Caller-defined data to pass to the callback procedure.
- *socketProtocol*  
Protocol (L2CAP, RFCOMM, or SDP) to use with this socket.

**Returns**    Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrParamError`  
Either `socketRefP` or `callbackP` is NULL.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

`btLibErrTooMany`

The maximum number of sockets allocated for the system has already been reached. The Bluetooth library supports a maximum of 16 socket connections.

**Comments** No callback events are generated when creating a socket.  
Before terminating, applications should close all of the sockets that they have created.

**See Also** [`BtLibSocketConnect\(\)`](#), [`BtLibSocketListen\(\)`](#),  
[`BtLibSocketClose\(\)`](#)

### BtLibSocketGetInfo Function

**Purpose** Retrieve information for a currently open socket.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketGetInfo (UInt16 btLibRefNum,  
BtLibSocketRef socket,  
BtLibSocketInfoEnum infoType, void *valueP,  
UInt32 valueSize)`

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *socket*  
Reference number for the socket to query.
- *infoType*  
Type of information to retrieve. See [`BtLibSocketInfoEnum`](#).
- ← *valueP*  
Buffer into which this function stores the result. You must allocate this buffer.
- *valueSize*  
Size, in bytes, of the valueP buffer. This size must match the size of the retrieved information.

**Returns** Returns one of the following values:

`btLibErrNoError`  
Success.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketGetInfo*

---

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrParamError`

One or more parameters is invalid. Be sure that the `valueSize` parameter matches the size of the information you're retrieving.

`btLibErrSdpNotMapped`

The SDP socket has not been mapped to a remote SDP service record. This error occurs when you try to obtain the SDP service record handle before you map socket to a remote service record using

[`BtLibSdpServiceRecordMapRemote\(\)`](#).

`btLibErrSocket`

The specified socket is invalid or not in use.

`btLibErrSocketRole`

The specified socket is not connected or has the wrong role for the request.

`btLibErrSocketProtocol`

The specified socket has the wrong protocol for the request.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**    **BtLibSocketInfoEnum**

The `BtLibSocketInfoEnum` enum allows you to specify which information you want to retrieve using the [`BtLibSocketGetInfo\(\)`](#) function.

#### **Prototype**

```
typedef enum {  
    btLibSocketInfo_Protocol = 0,  
    btLibSocketInfo_RemoteDeviceAddress,  
    btLibSocketInfo_SendPending = 100,  
    btLibSocketInfo_MaxTxSize,  
    btLibSocketInfo_MaxRxSize,  
    btLibSocketInfo_L2CapPsm = 200,  
    btLibSocketInfo_L2CapChannel,  
    btLibSocketInfo_RfCommServerId = 300,  
    btLibSocketInfo_RfCommOutstandingCredits,  
    btLibSocketInfo_SdpServiceRecordHandle = 400  
}
```

```
} BtLibSocketInfoEnum;
```

### Value Descriptions

`btLibSocketInfo_L2CapChannel`

`BtLibSocketGetInfo` returns a `BtLibL2CapChannelIDType` that represents the channel identifier for this socket. A `BtLibL2CapChannelIDType` is actually a `UInt16`. This information is valid for L2CAP sockets only. See the “Logical Link Control and Adaptation Protocol Specification” chapter of the *Specification of the Bluetooth System* for more information about channel identifiers.

`btLibSocketInfo_L2CapPsm`

`BtLibSocketGetInfo` returns a [BtLibL2CapPsmType](#) that represents the Protocol and Service Multiplexer (PSM) this socket is using to route packets. This information is only valid for L2CAP sockets.

`btLibSocketInfo_MaxRxSize`

`BtLibSocketGetInfo` returns a `UInt32` representing the maximum packet size the local device can receive.

`btLibSocketInfo_MaxTxSize`

`BtLibSocketGetInfo` returns a `UInt32` representing the maximum packet size the local device can transmit.

`btLibSocketInfo_Protocol`

`BtLibSocketGetInfo` returns a `BtLibProtocolEnum` representing the socket’s protocol. The members of this enum are `btLibL2CapProtocol`, `btLibRfCommProtocol`, and `btLibSdpProtocol`.

`btLibSocketInfo_RemoteDeviceAddress`

`BtLibSocketGetInfo` returns a [BtLibDeviceAddressType](#) representing the address of the device at the other end of this socket.

`btLibSocketInfo_RfCommServerId`

`BtLibSocketGetInfo` returns a [BtLibRfCommServerIdType](#) that represents the socket’s RFCOMM server channel. This information is valid for RFCOMM sockets only.

`btLibSocketInfo_RfCommOutstandingCredits`

`BtLibSocketGetInfo` returns a `UInt16` containing the number of remaining credits on this socket. This information is valid for RFCOMM sockets only.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketListen*

---

`btLibSocketInfo_SdpServiceRecordHandle`  
`BtLibSocketGetInfo` returns the [BtLibSdpRemoteServiceRecordHandle](#) for the service record associated with this socket. This information is valid for SDP sockets only.

`btLibSocketInfo_SendPending`  
`BtLibSocketGetInfo` returns a Boolean indicating whether a send is currently in progress.

### BtLibSocketListen Function

|                    |                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set up an L2CAP or RFCOMM socket as a listener.                                                                                                                                                                                                                                                                     |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err BtLibSocketListen (UInt16 btLibRefNum,     BtLibSocketRef socket,     BtLibSocketListenInfoType *listenInfo)</pre>                                                                                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>socket</i><br/>Reference number of the socket.</p> <p>↔ <i>listenInfo</i><br/>Protocol-specific listening information. For more information see <a href="#">BtLibSocketListenInfoType</a>. This parameter must not be NULL.</p> |
| <b>Returns</b>     | Returns one of the following values:                                                                                                                                                                                                                                                                                |
|                    | <pre>btLibErrNoError</pre> <p>Success. The socket is listening for incoming connections.</p>                                                                                                                                                                                                                        |

|                    | <pre>btLibErrNotOpen</pre> <p>The referenced Bluetooth library is not open.</p>                                                                                                                                                                                                                                     |
|                    | <pre>btLibErrParamError</pre> <p><i>listenInfo</i> is NULL.</p>                                                                                                                                                                                                                                                     |
|                    | <pre>btLibErrSocket</pre> <p>The specified socket is invalid.</p>                                                                                                                                                                                                                                                   |

`btLibErrSocketProtocol`

The protocol of the specified socket is not supported. This function only supports the L2CAP and RFCOMM protocols.

`btLibErrSocketRole`

The specified socket is already listening or connected.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

`btLibErrTooMany`

There are no resources to create a listener socket of this type.

## Comments

A listener socket waits for a remote device to initiate a connection to the local device and then generates a [btLibSocketEventConnectRequest](#) event to notify the application that it needs to handle the connection attempt.

You need to respond to this event with a call to [BtLibSocketRespondToConnection\(\)](#) on the listener socket to accept or reject the connection.

Under certain circumstances, the `listenInfo` parameter acts as an output as well as an input. See the documentation for `BtLibSocketListenInfoType` that follows.

## BtLibSocketListenInfoType

The `BtLibSocketListenInfoType` structure allows you to specify data specific to the protocol of the listening socket.

## Prototype

```
typedef struct BtLibSocketListenInfoType {
    union {
        ...
    } data;
} BtLibSocketListenInfoType;
```

This data is stored in the `data` field, which is a union consisting of two members: [L2Cap](#), and [RfComm](#). The member of the union that is valid depends on the protocol of the listening socket.

## L2Cap

Use the `L2Cap` union member if you're setting up a L2CAP socket as a listener. This member contains the following structure:

## Prototype

```
struct {
```

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketListen*

---

```
BtLibL2CapPsmType localPsm;  
UInt16 localMtu;  
UInt16 minRemoteMtu;  
} L2Cap;
```

#### Field Descriptions

localPsm

A [BtLibL2CapPsmType](#) representing the protocol and service multiplexer (PSM) identifier of the protocol to be used with this socket. You can identify your own protocol provided that its PSM value is odd, is within the range of 0x1001 to 0xFFFF, and has the 9th bit (0x0100) set to zero. These limitations are specified by the *Specification of the Bluetooth System*. If you set this field to BT\_L2CAP\_RANDOM\_PSM, the BtLibSocketListen function automatically creates a suitable PSM for the channel and returns it in this structure.

localMtu

The maximum transmission unit (MTU), or packet size, of the local device.

minRemoteMtu

The minimum packet size that your application can support.

#### **RfComm**

Use the RfComm union member if you're setting up a RFCOMM socket as a listener. This member contains the following structure:

**Prototype**

```
struct {  
    BtLibRfCommServerIdType serviceID;  
    UInt16 maxFrameSize;  
    UInt8 advancedCredit;  
} RfComm;
```

#### Field Descriptions

serviceID

A [BtLibRfCommServerIdType](#) representing the socket's RFCOMM service channel. It is assigned by RFCOMM and returned in this field when you call BtLibSocketListen.

### `maxFrameSize`

The maximum frame size your application can handle. This value must be between `BT_RF_MINFRAMESIZE` and `BT_RF_MAXFRAMESIZE`. If your application can handle any frame size, set this value to `BT_RF_DEFAULT_FRAMESIZE`.

### `advancedCredit`

An amount of credit the socket advances to the remote device when it successfully connects. Additional credit can be advanced using the [BtLibSocketAdvanceCredit\(\)](#) function once the connection has been established.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketRespondToConnection*

---

`btLibErrSocket`

The specified socket is invalid or not in use.

`btLibErrSocketProtocol`

The protocol of the specified socket is not supported. This function only supports the L2CAP and RFCOMM protocols.

`btLibErrSocketRole`

The specified socket is not a listener socket.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

You should call this function when you respond to a [btLibSocketEventConnectRequest](#) event delivered to a listener socket.

If the connection succeeds, the [btLibSocketEventConnectedInbound](#) event is generated and its status field is set to `btLibErrNoError`. If connection fails, the same event is generated with a non-zero status field, or a [btLibSocketEventDisconnected](#) is generated. In both cases, the status field indicates the reason for the failure.

Once the connection succeeds, a [btLibSocketEventData](#) callback event is generated whenever data received from the remote device. If the channel disconnects, a [btLibSocketEventDisconnected](#) is generated.

RFCOMM listener sockets and L2CAP listener sockets behave differently when you call this function. When you respond to an inbound L2CAP connection, a new L2CAP socket is created to exchange data with the remote device, and the L2CAP listener socket continues to listen for more connections. In other words, a single L2CAP listener socket can “spawn” several L2CAP sockets. This mechanism allows you to create a piconet.

On the other hand, when you respond to an RFCOMM connection, the RFCOMM listener socket becomes a connection socket through which you can exchange data with the remote device. If you want to create another RFCOMM connection, you need to create another listener socket.

## BtLibSocketSend Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Send data over a connected L2CAP or RFCOMM socket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Err BtLibSocketSend (UInt16 btLibRefNum,                     BtLibSocketRef socket, UInt8 *data,                     UInt32 dataLen)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>socket</i><br/>Reference number of the transmitting socket.</p> <p>→ <i>data</i><br/>Pointer to data to send. If the send returns <code>btLibErrPending</code>, the data buffer contents must remain intact until the <a href="#">btLibSocketEventSendComplete</a> event occurs.</p> <p>→ <i>dataLen</i><br/>Length of data to send. This value must be less than the Maximum Transmission Unit (MTU) for the socket. The MTU indicates the size of the largest packet that the remote device can receive and is determined when the socket is connected.</p>     |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><code>btLibErrPending</code><br/>The results will be returned through a callback event.</p> <p><code>btLibErrBusy</code><br/>A send is already in process.</p> <p><code>btLibErrNoAclLink</code><br/>An ACL link for the remote device does not exist</p> <p><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</p> <p><code>btLibErrSocket</code><br/>The specified socket is invalid.</p> <p><code>btLibErrSocketProtocol</code><br/>The protocol of the specified socket is not supported by this function. You can only send using the L2CAP and RFCOMM protocols.</p> |

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSocketSend*

---

`btLibErrSocketRole`

The specified socket is not connected.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

When the data has been sent successfully, a [`btLibSocketEventSendComplete`](#) callback event is generated and its status field is set to `btLibErrNoError`. If the data is not sent successfully, the same callback event is generated with a non-zero status field.

Note that there can be only one send in progress at a time per socket. You must wait for the [`btLibSocketEventSendComplete`](#) event before sending another packet.

## BtLibSdpGetPSMByUuid Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Get an available L2CAP PSM using SDP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>Err BtLibSdpGetPsmByUuid (UInt16 btLibRefNum,<br/>    BtLibSocketRef socket,<br/>    BtLibDeviceAddressType *remoteDeviceP,<br/>    BtLibSdpUuidType *serviceUuidList,<br/>    UInt8 uuidListLen)</pre>                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <ul style="list-style-type: none"><li>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</li><li>→ <i>socket</i><br/>Reference number for an SDP socket.</li><li>→ <i>remoteDeviceP</i><br/>Device address of a remote device to query. This parameter must not be NULL.</li><li>→ <i>serviceUuidList</i><br/>Array of UUIDs that must match those of the service record. This parameter must not be NULL.</li><li>→ <i>uuidListLen</i><br/>Length of serviceUuidList. A maximum of 12 entries is allowed.</li></ul>                                                                                   |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <ul style="list-style-type: none"><li><code>btLibErrPending</code><br/>The PSM value will be returned through a callback event.</li><li><code>btLibErrNotOpen</code><br/>The referenced Bluetooth library is not open.</li><li><code>btLibErrOutOfMemory</code><br/>Not enough memory to complete request</li><li><code>btLibErrParamError</code><br/>One or more parameters is invalid.</li><li><code>btLibErrSocket</code><br/>The specified socket is invalid or not in use.</li><li><code>btLibErrSocketRole</code><br/>The specified socket is not connected.</li></ul> |

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function returns the L2CAP PSM of the first SDP record on the remote device that contains all the specified UUIDs.

This function generates a [`btLibSocketEventSdpGetPsmByUuid`](#) event when the query completes or fails.

**See Also** [`BtLibSdpGetServerChannelByUuid\(\)`](#)

## BtLibSdpGetRawDataElementSize Macro

**Purpose** Returns a constant representing the data element's size.

**Declared In** `BtLib.h`

**Prototype** `#define BtLibSdpGetRawDataElementSize (header)`

**Parameters** `→ header`  
First byte of a data element

**Returns** A constant representing the size of the data element.

**Comments** The first byte of a SDP data element contains the type and size of the data element.

The result of this macro is one of the following constants:

### Data Element Sizes

`btLibDESD_1BYTE`

A 1-byte element. However, if the data element's type is `btLibDETD_NIL` then the size is 0 bytes.

`btLibDESD_2BYTES`

A 2-byte element.

`btLibDESD_4BYTES`

A 4-byte element.

`btLibDESD_8BYTES`

An 8-byte element.

`btLibDESD_16BYTES`

A 16-byte element.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpGetRawDataElementType*

---

`btLibDESD_ADD_8BITS`

The element's actual data size, in bytes, is contained in the next 8 bits.

`btLibDESD_ADD_16BITS`

The element's actual data size, in bytes, is contained in the next 16 bits.

`btLibDESD_ADD_32BITS`

The element's actual data size, in bytes, is contained in the next 32 bits.

These size constants are discussed in greater detail in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

[`BtLibSdpParseRawDataElement\(\)`](#),  
[`BtLibSdpVerifyRawDataElement\(\)`](#)

## **BtLibSdpGetRawDataElementType Macro**

**Purpose** Returns an SDP data element's type.

**Declared In** `BtLib.h`

**Prototype** `#define BtLibSdpGetRawDataElementType (header)`  
`→ header`  
The first byte of a data element

**Returns** The type of the data element.

**Comments** The first byte of a SDP data element contains the type and size of the data element.

The result of this macro is one of the following constants:

### **Data Element Types**

`btLibDETD_NIL`

Nil, the null type

`btLibDETD_UINT`

Unsigned Integer.

`btLibDETD_SINT`

Signed Integer

`btLibDETD_UUID`  
UUID, a universally unique identifier

`btLibDETD_TEXT`  
Text string

`btLibDETD_BOOL`  
Boolean

`btLibDETD_SEQ`  
Data element sequence

`btLibDETD_ALT`  
Data element alternative

`btLibDETD_URL`  
URL, a uniform resource locator

These types are discussed in greater detail in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

## BtLibSdpGetServerChannelByUuid Function

**Purpose** Get an available RFCOMM server channel using SDP.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpGetServerChannelByUuid  
(UInt16 btLibRefNum, BtLibSocketRef socket,  
BtLibDeviceAddressType *remoteDeviceP,  
BtLibSdpUuidType *serviceUuidList,  
UInt8 uuidListLen)`

**Parameters**

- `btLibRefNum`  
Reference number for the Bluetooth library.
- `socket`  
Reference number for an SDP socket.
- `remoteDeviceP`  
Device address of a remote device to query. This parameter must not be NULL.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpGetServerChannelByUuid*

---

→ *serviceUuidList*

Array of UUIDs that must match those of the service record.  
This parameter must not be NULL.

→ *uuidListLen*

Length of serviceUuidList. A maximum of 12 entries is allowed.

**Returns** Returns one of the following values:

*btLibErrPending*

The server channel will be returned through a callback event.

*btLibErrNotOpen*

The referenced Bluetooth library is not open.

*btLibErrOutOfMemory*

Not enough memory to complete request

*btLibErrParamError*

One or more parameters is invalid.

*btLibErrSocket*

The specified socket is invalid or not in use.

*btLibErrSocketRole*

The specified socket is not connected.

*btLibErrStackNotOpen*

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function returns the RFCOMM server channel number of the first SDP record on the remote device that contains all the specified UUIDs.

This function generates a [\*btLibSocketEventSdpGetServerChannelBy Uuid\*](#) event when the query completes or fails.

**See Also** [\*BtLibSdpGetPSMByUuid\(\)\*](#)

## BtLibSdpParseRawDataElement Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Parse a raw SDP data element to determine where the data field begins and the size of the data field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Comments</b>    | <p>A data element has three fields. The first field, called the <i>header field</i>, identifies the type of value stored in the data element and the size of the element. The second field, called the <i>size field</i>, contains more information about the size of the data if it's not completely specified by the header. Otherwise the size field is omitted. The third field, called the <i>data field</i>, contains the data element's actual value.</p> <p>The offset this function returns is the offset between the start of the data element and the data field. The size this function returns is the</p> |

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpServiceRecordCreate*

---

the size of the data field. Note that the sum of the offset and the size is the size of the data element.

This function is especially useful for iterating through entries in a list attribute.

The *Specification of the Bluetooth System* has more information about the structure of a data element.

              [BtLibSdpGetRawDataElementSize\(\)](#)

## **BtLibSdpServiceRecordCreate Function**

**Purpose**        Allocate a memory chunk that represents an SDP service record.

**Declared In**   `BtLib.h`

**Prototype**    `Err BtLibSdpServiceRecordCreate`  
                  `(UInt16 btLibRefNum,`  
                  `BtLibSdpRecordHandle *recordH)`

**Parameters**    $\rightarrow$  `btLibRefNum`  
                  Reference number for the Bluetooth library.

$\leftarrow$  `recordH`  
                  SDP memory handle for the new SDP memory record.

**Returns**       Returns one of the following values:

`btLibErrNoError`  
                  Success.

`btLibErrNotOpen`  
                  The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`  
                  Not enough memory to allocate the memory chunk.

`btLibErrParamError`  
                  `recordH` is NULL.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**See Also** [`BtLibSdpServiceRecordDestroy\(\)`](#),  
[`BtLibSdpServiceRecordStartAdvertising\(\)`](#),  
[`BtLibSdpServiceRecordStopAdvertising\(\)`](#)

## BtLibSdpServiceRecordDestroy Function

**Purpose** Free the memory associated with a SDP memory record.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordDestroy`  
`(UInt16 btLibRefNum,`  
`BtLibSdpRecordHandle recordH)`

**Parameters**  $\rightarrow$  `btLibRefNum`  
Reference number for the Bluetooth library.

$\rightarrow$  `recordH`  
SDP memory handle associated with the memory chunk to be freed.

**Returns** Returns one of the following values:

`btLibErrNoError`  
Success.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrParamError`  
`recordH` does not refer to an valid SDP memory record.

`btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function stops advertising the record before it frees it.

**See Also** [`BtLibSdpServiceRecordCreate\(\)`](#),  
[`BtLibSdpServiceRecordStartAdvertising\(\)`](#),  
[`BtLibSdpServiceRecordStopAdvertising\(\)`](#)

## BtLibSdpServiceRecordGetAttribute Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Retrieve the value of a specific attribute in a SDP memory record. If the attribute is a list or a protocol descriptor list (a list of lists), this function retrieves the value of a specific list entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err BtLibSdpServiceRecordGetAttribute     (UInt16 btLibRefNum,      BtLibSdpRecordHandle recordH,      BtLibSdpAttributeIdType attributeID,      BtLibSdpAttributeDataType *attributeValues,      UInt16 listNumber, UInt16 listEntry)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>recordH</i><br/>Handle identifying the SDP memory record.</p> <p>→ <i>attributeID</i><br/>Attribute identifier of the attribute to retrieve.</p> <p>← <i>attributeValues</i><br/>Buffer into which this function stores the attribute's value.<br/>You must allocate this buffer. This pointer must not be NULL.</p> <p>→ <i>listNumber</i><br/>List to query if the attribute is a protocol descriptor list.<br/>Otherwise this parameter is ignored.</p> <p>→ <i>listEntry</i><br/>Item to get in the list if the attribute is a list attribute.<br/>Otherwise this parameter is ignored.</p> |
| <b>Returns</b>     | Returns one of the following values:<br><br><code>btLibErrNoError</code><br>Success.<br><br><code>btLibErrPending</code><br>The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.                                                                                                                                                                                                                                                                                                                                                                                                                    |

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle or `attributeValues` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### Comments

If the specified SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetAttribute`](#) event when the result is available or the query fails. In this case, the buffer to which `attributeValues` points must not be freed before the event occurs; making the buffer global ensures that it remains over the duration of the SDP query.

If you are retrieving a string or a URL, you need to allocate additional space. See the documentation for [`BtLibSdpAttributeDataType`](#) for more information.

## Bluetooth Library: Sockets and Service Discovery

*BtLibSdpServiceRecordGetNumListEntries*

---

This function supports the universal attributes defined in “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

**See Also**    [BtLibSdpServiceRecordSetAttribute\(\)](#),  
              [BtLibSdpServiceRecordMapRemote\(\)](#),  
              [BtLibSdpServiceRecordGetNumListEntries\(\)](#),  
              [BtLibSdpServiceRecordGetNumLists\(\)](#),  
              [BtLibSdpServiceRecordGetStringOrUrlLength\(\)](#)

### BtLibSdpServiceRecordGetNumListEntries Function

**Purpose**        Get the number of entries in a list attribute.

**Declared In**   `BtLib.h`

**Prototype**    `Err BtLibSdpServiceRecordGetNumListEntries`  
                  `(UInt16 btLibRefNum,`  
                  `BtLibSdpRecordHandle recordH,`  
                  `BtLibSdpAttributeIdType attributeID,`  
                  `UInt16 listNumber, UInt16 *numEntries)`

**Parameters**    `→ btLibRefNum`  
                  Reference number for the Bluetooth library.

`→ recordH`  
                  Handle identifying the SDP memory record.

`→ attributeID`  
                  Attribute identifier of the attribute whose number of list entries is retrieved.

`→ listNumber`  
                  List to query if the attribute is a ProfileDescriptorListEntry. Otherwise this parameter is ignored.

`← numEntries`  
                  Number of entries in the list.

**Returns**        Returns one of the following values:  
                  `btLibErrNoError`  
                  Success

`btLibErrPending`

The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

Another query is pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform this query.

`btLibErrParamError`

`recordH` is an invalid handle or `numEntries` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to open when the library was opened.

#### Comments

This function supports the universal attributes defined in “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*. Specifically, this function gives valid results for `ServiceClassIdList`, `ProtocolDescriptorList`, `BrowseGroupList`, `LanguageBaseAttributeIDList`, and `ProfileDescriptorList` attributes.

If the specified SDP memory record refers to a service record on a remote device, this function generates a

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpServiceRecordGetNumLists*

---

[btLibSocketEventSdpGetNumListEntries](#) event when the result is available or the query fails.

**See Also** [BtLibSdpServiceRecordGetNumLists\(\)](#),  
[BtLibSdpServiceRecordGetAttribute\(\)](#),  
[BtLibSdpServiceRecordGetStringOrUrlLength\(\)](#),

## BtLibSdpServiceRecordGetNumLists Function

**Purpose** Get the number of lists in a protocol descriptor list SDP attribute.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordGetNumLists
    (UInt16 btLibRefNum,
     BtLibSdpRecordHandle recordH,
     BtLibSdpAttributeIdType attributeID,
     UInt16 *numLists)
```

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *recordH*  
Handle identifying the SDP memory record.
- *attributeID*  
Attribute identifier of the attribute whose number of lists is retrieved.
- ← *numLists*  
Number of lists.

**Returns** Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrPending`  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.
- `btLibErrBusy`  
The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

Another query is pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform this query.

`btLibErrParamError`

`recordH` is an invalid handle or `numLists` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to open when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetNumLists`](#) event when the result is available or the query fails.

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle, value is NULL, `valSize` is 0, or the size of the attribute value is larger than `valSize`.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetRawAttribute`](#) event when the result is available or the query fails.

**See Also** [`BtLibSdpServiceRecordSetRawAttribute\(\)`](#),

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the size, in bytes, of any attribute of an SDP memory record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <pre>Err BtLibSdpServiceRecordGetSizeOfRawAttribute     (UInt16 btLibRefNum,      BtLibSdpRecordHandle recordH,      BtLibSdpAttributeIdType attributeID,      UInt16 *size)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>btLibRefNum</i><br/>Reference number for the Bluetooth library.</p> <p>→ <i>recordH</i><br/>Handle identifying the SDP memory record.</p> <p>→ <i>attributeID</i><br/>Attribute identifier of the attribute whose size is retrieved.</p> <p>← <i>size</i><br/>Pointer to a UInt16 to store the size of the attribute. This parameter must not be NULL.</p>                                                                                                                                                                                                                                                                                                                |
| <b>Returns</b>     | Returns one of the following values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                    | <p><code>btLibErrNoError</code><br/>Success.</p> <p><code>btLibErrPending</code><br/>The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.</p> <p><code>btLibErrBusy</code><br/>The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.</p> <p><code>btLibErrInProgress</code><br/>A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.</p> <p><code>btLibErrNoAclLink</code><br/>An ACL link to the remote device does not exist.</p> |

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle or size is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetRawAttributeSize`](#) event when the result is available or the query fails.

**See Also** [`BtLibSdpServiceRecordGetRawAttribute\(\)`](#),  
[`BtLibSdpServiceRecordMapRemote\(\)`](#),  
[`BtLibSdpServiceRecordSetRawAttribute\(\)`](#)

## BtLibSdpServiceRecordGetStringOrUrlLength Function

**Purpose** Get the length of a string or URL attribute in a SDP memory record.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordGetStringOrUrlLength
    (UInt16 btLibRefNum,
     BtLibSdpRecordHandle recordH,
     BtLibSdpAttributeIdType attributeID,
     UInt16 *length)
```

**Parameters**

- `btLibRefNum`  
Reference number for the Bluetooth library.
- `recordH`  
Handle identifying the SDP memory record.
- `attributeID`  
Attribute identifier of the attribute whose length is retrieved.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpServiceRecordGetStringOrUrlLength*

---

← *length*

Pointer to a UInt16 where the length of the attribute is stored.  
This parameter cannot be NULL.

**Returns** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrPending`

The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

The recordH does not refer to a valid handle, length is NULL, or the attribute is not a string or a URL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified SDP record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** Bluetooth strings do not include a null terminator.

If the SDP memory record refers to a service record on a remote device, this function generates a

[`btLibSocketEventSdpGetStringLen`](#) event when the result is available or the query fails.

**See Also** [`BtLibSdpServiceRecordGetAttribute\(\)`](#),  
[`BtLibSdpServiceRecordGetNumListEntries\(\)`](#),  
[`BtLibSdpServiceRecordGetNumLists\(\)`](#),  
[`BtLibSdpServiceRecordMapRemote\(\)`](#)

## BtLibSdpServiceRecordMapRemote Function

**Purpose** Configure an SDP memory record so it refers to a service record on a remote device.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordMapRemote
    (UInt16 btLibRefNum, BtLibSocketRef socket,
     BtLibDeviceAddressType *remoteDeviceP,
     BtLibSdpRemoteServiceRecordHandle remoteHandle
     , BtLibSdpRecordHandle recordH)
```

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *socket*  
Reference number of an SDP socket.
- *remoteDeviceP*  
Device to query.
- *remoteHandle*  
Remote service record handle.
- *recordH*  
SDP memory handle of an empty SDP record.

**Returns** Returns one of the following values:

- `btLibErrNoError`  
The mapping was successful.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrOutOfMemory`  
Not enough memory to perform mapping.

## Bluetooth Library: Sockets and Service Discovery

*BtLibSdpServiceRecordSetAttribute*

---

`btLibErrParamError`

recordH is invalid or refers to an invalid memory chunk.

`btLibErrSdpMapped`

The SDP memory record is already mapped to a remote service record.

`btLibErrSocket`

The specified socket is invalid or not in use.

`btLibErrSocketProtocol`

The specified socket is not an SDP socket.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You must create an SDP memory record using [`BtLibSdpServiceRecordCreate\(\)`](#) before using this function.

Note that this function does not copy the contents of the remote service record to the SDP memory record in local memory.

### BtLibSdpServiceRecordSetAttribute Function

**Purpose** Set the value of an attribute in an SDP memory record. If the attribute is a list or a protocol descriptor list (a list of lists), this function sets the value of a specific list entry. The SDP memory record must represent a local unadvertised service record.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordSetAttribute
    (UInt16 btLibRefNum,
     BtLibSdpRecordHandle recordH,
     BtLibSdpAttributeIdType attributeID,
     BtLibSdpAttributeDataType *attributeValue,
     UInt16 listNumber, UInt16 listEntry)
```

**Parameters**

- `btLibRefNum`  
Reference number for the Bluetooth library.
- `recordH`  
Handle of the service record to modify.
- `attributeID`  
Attribute identifier of the attribute to set.

→ *attributeValue*

Pointer to the new value for the attribute. This pointer must not be NULL.

→ *listNumber*

List to modify if the attribute is a protocol descriptor list. Otherwise this parameter is ignored.

→ *listEntry*

Item to set in the list if the attribute is a list attribute. Otherwise this parameter is ignored.

**Returns** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrAdvertised`

An advertised record was passed in `recordH`. The record must not be advertised.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to set the attribute.

`btLibErrParamError`

`recordH` is invalid or `attributeValue` is NULL.

`btLibErrRemoteRecord`

A remote record was passed in `recordH`. The record must be local.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function only works on SDP memory records that are local and not advertised. You can advertise the record after you finish modifying it.

This function supports the universal attributes defined in the *Specification of the Bluetooth System*.

[`BtLibSdpServiceRecordGetAttribute\(\)`](#),  
[`BtLibSdpServiceRecordStartAdvertising\(\)`](#),  
[`BtLibSdpServiceRecordStopAdvertising\(\)`](#)

## BtLibSdpServiceRecordSetAttributesForSocket Function

- Purpose** Initialize an SDP memory record so it can represent an existing L2CAP or RFCOMM listener socket as a service.
- Declared In** `BtLib.h`
- Prototype**
- ```
Err BtLibSdpServiceRecordSetAttributesForSocket
    (UInt16 btLibRefNum, BtLibSocketRef socket,
     BtLibSdpUuidType *serviceUUIDList,
     UInt8 uuidListLen, const Char *serviceName,
     UInt16 serviceNameLen,
     BtLibSdpRecordHandle recordH)
```
- Parameters**
- *btLibRefNum*  
Reference number for the Bluetooth library.
  - *socket*  
Reference number for an RFCOMM or L2CAP socket in listening mode.
  - *serviceUUIDList*  
List of UUIDs for the service record.
  - *uuidListLen*  
Number of entries in serviceUUIDList. A maximum of 12 entries is allowed.
  - *serviceName*  
User-friendly name for the service in English.
  - *serviceNameLen*  
Size, in bytes, of serviceName.
  - *recordH*  
Handle of the service record to be initialized.
- Returns** Returns one of the following values:
- `btLibErrNoError`  
Success.
  - `btLibErrAdvertised`  
The record specified by recordH is being advertised. You must stop advertising the record before you can change it.
  - `btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to store the contents of the SDP record.

`btLibErrParamError`

`recordH` is not a valid record handle.

`btLibErrRemoteRecord`

A remote record was passed in `recordH`. Because the service is local, the record must be local.

`btLibErrSocket`

The specified socket is invalid or not in use.

`btLibErrSocketRole`

The specified socket is not a listener socket.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You must first create an SDP record using [`BtLibSdpServiceRecordCreate\(\)`](#). However, the record must not be advertised. In other words, don't call [`BtLibSdpServiceRecordStartAdvertising\(\)`](#) until after calling this function.

**See Also** [`BtLibSdpServiceRecordCreate\(\)`](#), [`BtLibSocketListen\(\)`](#)

## BtLibSdpServiceRecordSetRawAttribute Function

**Purpose** Set the value for an attribute of a SDP memory record. This function allows you to specify the attribute as an array of bytes in the format defined in the "Service Discovery Protocol" chapter of the

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpServiceRecordSetRawAttribute*

---

*Specification of the Bluetooth System.* The SDP memory record must represent a local unadvertised service record.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordSetRawAttribute  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH,  
BtLibSdpAttributeIdType attributeID,  
const UInt8 *value, UInt16 valSize)`

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *recordH*  
Handle identifying the SDP memory record.
- *attributeID*  
Attribute identifier of the attribute to set.
- *value*  
Array of bytes containing SDP attribute data in the format defined in the SDP protocol. This parameter must not be NULL.
- *valSize*  
Size, in bytes, of value. This parameter must not be 0.

**Returns** Returns one of the following values:

`btLibErrNoError`  
Success.

`btLibErrAdvertised`  
`recordH` is being advertised. The record must not be advertised.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`  
Not enough memory to set the attribute.

`btLibErrParamError`  
`recordH` is invalid, `value` is NULL, or `valSize` is 0.

`btLibErrRemoteRecord`  
`recordH` refers to a service record on a remote device. The service record must be local.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the service record is being advertised, you must stop advertising it before you modify it.

**See Also** [`BtLibSdpServiceRecordGetRawAttribute\(\)`](#),  
[`BtLibSdpServiceRecordSetAttribute\(\)`](#),  
[`BtLibSdpServiceRecordStopAdvertising\(\)`](#),  
[`BtLibSdpServiceRecordStartAdvertising\(\)`](#)

## BtLibSdpServiceRecordsGetByServiceClass Function

**Purpose** Get the service record handles corresponding to the service classes advertised on a remote device.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordsGetByServiceClass
    (UInt16 btLibRefNum, BtLibSocketRef socket,
     BtLibDeviceAddressType *remoteDeviceP,
     BtLibSdpUuidType *uuidList,
     UInt16 uuidListLen,
     BtLibSdpRemoteServiceRecordHandle *srvRecList,
     UInt16 *numSrvRec)
```

**Parameters**

- *btLibRefNum*  
Reference number for the Bluetooth library.
- *socket*  
Reference number of an SDP socket.
- *remoteDevice*  
Remote device to query.
- *uuidList*  
Array of UUIDs identifying the service classes. This parameter must not be NULL.
- *uuidListLen*  
Number of elements in the *uuidList*. You can specify a maximum of 12 UUIDs.

## Bluetooth Library: Sockets and Service Discovery

### *BtLibSdpServiceRecordsGetByServiceClass*

---

← *srvRecList*

Array of service record handles into which this function stores the results of the SDP query. You must allocate this array. This pointer must not be NULL.

↔ *numSrvRec*

Number of service records allocated in *srvRecList*. This value is sent to the SDP server so it can limit the number of responses. On return, the actual number of records retrieved.

**Returns** Returns one of the following values:

*btLibErrPending*

The results will be returned through a callback event.

*btLibErrBusy*

The connection to the remote device is parked.

*btLibErrInProgress*

A SDP query is already in progress on this socket.

*btLibErrNoAclLink*

An ACL link to the remote device does not exist.

*btLibErrNotOpen*

The referenced Bluetooth library is not open.

*btLibErrOutOfMemory*

Not enough memory to perform the query.

*btLibErrParamError*

One or more parameters are invalid.

*btLibErrSocket*

The specified socket is invalid or not in use.

*btLibErrSocketProtocol*

The specified socket is not an SDP socket.

*btLibErrStackNotOpen*

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You need to allocate *srvRecList*, an array of [\*BtLibSdpRemoteServiceRecordHandles\*](#) large enough to accommodate all of the service record handles corresponding to the specified service classes. Specify the size of the array using the *numSrvRec* parameter.

This function generates a [btLibSocketEventSdpServiceRecordHandle](#) event when the matching service records are available or the query fails.

## BtLibSdpServiceRecordStartAdvertising Function

<b>Purpose</b>	Make visible an SDP memory record representing a local SDP service record. Remote devices can access visible service records through SDP.
<b>Declared In</b>	<code>BtLib.h</code>
<b>Prototype</b>	<pre>Err BtLibSdpServiceRecordStartAdvertising     (UInt16 btLibRefNum,      BtLibSdpRecordHandle recordH)</pre>
<b>Parameters</b>	<p>→ <i>btLibRefNum</i> Reference number for the Bluetooth library.</p> <p>→ <i>recordH</i> Handle of the service record to make available to remote devices.</p>
<b>Returns</b>	Returns one of the following values:
	<code>btLibErrNoError</code> Success
	<code>btLibErrNotOpen</code> The referenced Bluetooth library is not open.
	<code>btLibErrParamError</code> <code>recordH</code> is not a valid record handle.
	<code>btLibErrRemoteRecord</code> <code>recordH</code> refers to a remote record. The record must be local.
	<code>btLibErrSdpAdvertised</code> The service record is already accessible by remote devices.
	<code>btLibErrStackNotOpen</code> The Bluetooth stack failed to initialize when the library was opened.

## Bluetooth Library: Sockets and Service Discovery

*BtLibSdpServiceRecordStopAdvertising*

---

**Comments** You cannot modify an SDP memory record while it is available to remote devices.

**See Also** [BtLibSdpServiceRecordStopAdvertising\(\)](#)

### BtLibSdpServiceRecordStopAdvertising Function

**Purpose** Hide an SDP memory record representing a local SDP service record. Remote devices cannot access hidden service records through SDP.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordStopAdvertising  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH)`

**Parameters** `→ btLibRefNum`  
Reference number for the Bluetooth library.  
`→ recordH`  
Handle of the service record to hide.

**Returns** Returns one of the following values:

- `btLibErrNoError`  
Success. The SDP record is no longer available to remote devices.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrParamError`  
recordH is not a valid record handle.
- `btLibErrRemoteRecord`  
recordH refers to a remote record. The record must be local.
- `btLibErrSdpNotAdvertised`  
The service record is already hidden from remote devices.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**See Also** [BtLibSdpServiceRecordStartAdvertising\(\)](#)

## **BtLibSdpUuidInitialize Macro**

<b>Purpose</b>	Sets the value of a UUID.
<b>Declared In</b>	<code>BtLib.h</code>
<b>Prototype</b>	<pre>#define BtLibSdpUuidInitialize (uuid, value,                                valSize)</pre>
<b>Parameters</b>	<p><code>uuid</code> <a href="#">BtLibSdpUuidType</a> to initialize.</p> <p><code>value</code> Array of bytes representing the UUID. The size of this array depends on <code>valSize</code>.</p> <p><code>valSize</code> <a href="#">BtLibSdpUuidSizeEnum</a> member specifying the size of the value array.</p>
<b>Returns</b>	None.

## **BtLibSdpVerifyRawDataElement Function**

<b>Purpose</b>	Verify that a raw SDP data element is properly formed.
<b>Declared In</b>	<code>BtLib.h</code>
<b>Prototype</b>	<pre>Err BtLibSdpVerifyRawDataElement     (UInt16 btLibRefNum, const UInt8 *value,      UInt16 valSize, UInt8 maxLevel)</pre>
<b>Parameters</b>	<p>→ <i>btLibRefNum</i> Reference number for the Bluetooth library.</p> <p>→ <i>value</i> Raw SDP attribute data.</p> <p>→ <i>valSize</i> Size of value, in bytes. The size of the data element must be less than or equal to this parameter, otherwise this function fails.</p> <p>→ <i>maxLevel</i> Maximum level of recursion over which this function verifies the data element. Must be at least one.</p>
<b>Returns</b>	Returns one of the following values:

## Bluetooth Library: Sockets and Service Discovery

### *Application-Defined Functions*

---

`btLibErrNoError`

SDP data element is properly formatted.

`btLibErrError`

SDP data element is not properly formatted.

`btLibErrNotOpen`

The reference Bluetooth library is not open.

`btLibErrParamError`

value is NULL.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

This function checks all size descriptors in the element to ensure that the data element fits into the indicated length. In the case of data element sequences or alternates, this function calls itself recursively.

The `maxLevel` parameter specifies the maximum number of times this function calls itself. Limiting the recursion level prevents an infinite loop if the data is bad. `maxLevel` must be large enough to handle the complete data element. For example, to verify a simple data element such as an unsigned integer, `maxLevel` must be at least 1. To verify a data element sequence of UUIDs, `maxLevel` must be at least 2.

## Application-Defined Functions

This section describes the callback functions that handle socket events. These functions are supplied by the developer and can be named anything.

## **BtLibSocketCallback Function**

<b>Purpose</b>	Signal the result of a Bluetooth socket event. When the event takes place, this callback function is called.
<b>Declared In</b>	<code>BtLibTypes.h</code>
<b>Prototype</b>	<pre>void (*BtLibSocketProcPtr)     (BtLibSocketEventType *sEvent, UInt32 refCon)</pre>
<b>Parameters</b>	<p>→ <i>sEvent</i> <a href="#">BtLibSocketEventType</a> structure containing the event parameters.</p> <p>→ <i>refCon</i> General purpose integer which you can use to hold application-specific information. When you call <a href="#">BtLibSocketCreate()</a> to create the socket, you can specify a value to pass to this parameter.</p>
<b>Returns</b>	Returns nothing.
<b>Comments</b>	<p>The event and status of the event are in the <i>sEvent</i> structure. See <a href="#">Socket Callback Events</a> for more information.</p> <p>You must specify this callback function when you create a socket. You do this by calling <a href="#">BtLibSocketCreate()</a>.</p>

# Cryptography Provider Manager

---

The Cryptography Provider Manager (CPM) is a shared library that acts as a framework for cryptographic services. These services are divided into two levels:

- At the application level, the CPM provides an API that any application can use to perform cryptographic operations.
- The operations themselves are not part of the CPM; instead, they're provided by an **algorithm provider** (or **AP**). To export its functionality to the CPM, an algorithm provider implements a set of callback functions. Third party developers can create and distribute their own APs. The Palm OS provides a default algorithm provider that's used in the absence of alternatives.

The CPM provides the glue between an application and an AP. In general, this glue is invisible: You don't need to know anything about the APs that are available to use their cryptographic services. This makes it possible for an application to use common cryptographic operations without having to be overly concerned with the exact implementation of these operations. It also relieves the algorithm providers from the duty of providing their own invocation API.

---

**NOTE:** In Palm OS 5, only the application level API is offered; the ability to create and install your own algorithm provider will be supported in a later release.

---

## The Default Provider

In Palm OS 5, there is only one algorithm provider. Implemented by RSA, it provides three cryptographic services:

- Data encryption and decryption using an RC4 symmetric key stream cipher
- Message digest creation (hashing) using the SHA-1 algorithm.
- Message verification through a combination of the two other operations.

All of the Palm OS 5 cryptography operations are provided by RSA.

One of the features of the CPM library is that the developer doesn't need to know anything about cryptography. The functions are designed such that the default settings will yield satisfying results.

## Fundamental CPM Functions

The fundamental cryptography functions are:

- [`CPMLibEncrypt\(\)`](#) performs a data encryption operation.
- [`CPMLibDecrypt\(\)`](#) performs a data decryption operation.
- [`CPMLibHash\(\)`](#) creates a message digest.
- [`CPMLibVerify\(\)`](#) verifies a message that has a signature and certificate.

These functions operate on blocks of data. For example, [`CPMLibEncrypt\(\)`](#) takes a block of data (and a key), encrypts it, and hands back the encrypted data all in one go.

The CPM also provides sets of functions that let you perform these operations sequentially, allowing you to (for example) initialize an encryption "stream," iteratively feed data to the encryption algorithm, and then "finalize" the stream and get the encrypted data back. These functions are (for encryption) [`CPMLibEncryptInit\(\)`](#), [`CPMLibEncryptUpdate\(\)`](#), and [`CPMLibEncryptFinal\(\)`](#).

## Using the Crypto-Info Structures

The cryptography operations that are currently supported by the CPM library rely on four “crypto-info” data structures:

- The [APKeyInfoStruct](#) describes a symmetric key,
- [APCipherInfoStruct](#) describes an encryption/decryption operation.
- [APHashInfoStruct](#) describes message digest creation.
- [APVerifyInfoStruct](#) describes a message verification operation.

When you perform a cryptographic operation, you’ll be asked for one or more of these structures. In most cases you can pass in an “empty” structure and the function will populate it for you. However, it’s important that you zero the structure first.

For example, the [CPMLibHash\(\)](#) function takes a [APHashInfoStruct](#) as an argument. To use the default hashing operations, simply allocate the structure, zero it, and pass it in:

---

```
APHashInfoType hashinfo;  
MemSet ((void *)&hashinfo, sizeof (APHashInfoType), 0);  
CPMLibHash( ..., &hashInfo, ...);
```

---

When you’re done with a crypto-info structure, you must “release” it:

---

```
CPMLibReleaseHashInfo( ..., &hashInfo );
```

---

## Using the Export Functions

The cryptography structures (key, hash, cipher, verification) can be “exported,” or encoded into a form that can be cached. These operations are provided by the `CPMLibExportObjectInfo` functions. Purposeful details of exporting (and importing, its functional complement) are given in the individual function descriptions, below. This little section touches on a wrinkle of usage.

When you use an export function, you’re asked to supply a buffer that can accommodate the encoded data. This means that you have

## Cryptography Provider Manager

### *Using the Export Functions*

---

to know how big the encoded data will be; the export function itself tells you the size through its final (reference) argument. Thus, you have to call the export function twice: Once to get the buffer size, and then again to actually get the encoded data. This is demonstrated below:

---

```
UInt32 length=0;
UInt8 *data=NULL;
Err error;

/* For demo purposes, we're only interested in the last two
 * arguments (the buffer and the buffer length). First, we
 * set the buffer to NULL, and retrieve the length.
 */
error = CPMLibExport... (... NULL, &length);

/* At this pass, we expect the function to tell us that
 * the buffer is too small. Any other return is treated
 * as an error. Note that the <length> argument is reset to
 * to the required allocation length despite the error
 * return.
 */
if (error != cpmErrBufTooSmall)
    return ...; // or whatever

/* Allocate the buffer (for brevity, the example omits
 * the error check).
 */
data = MemPtrNew(length);

/* Call the export function again to retrieve the
 * encoded data.
 */
error = CPMLibExport... ( ... data, &length);

/* This time we want a 'clean' return. */
if (error != errNone) {
    // handle the error
}
```

---

## CPM and AP Constants

### AP Capability Constants

The AP capability values are bitfield constants that represent the capabilities that an AP supports. The capability constants are OR'd into the `flags` field of the [APProviderInfoStruct](#) structure.

Declared in `CPMLibCommon.h`, the constants are:

---

<code>APF_MP</code>	Streaming operations (initialize/update/finalize) are supported ("MP" stands for "multiple part"). See <a href="#">"Fundamental CPM Functions"</a> for details. Note that all APs are expected to support block operations.
<code>APF_HW</code>	The AP's algorithms are implemented in hardware (such as a SmartCard).
<code>APF_KEYGEN</code>	Symmetric key operations (including key info import and export) are supported.
<code>APF_KEYPAIRGEN</code>	Asymmetric key operations (including key info import and export) are supported.
<code>APF_KEYDERIVE</code>	Key derivation is supported.
<code>APF_HASH</code>	Hashing operations (including hash info import and export) are supported.
<code>APF_CIPHER</code>	Message encryption and decryption operations (including cipher info import and export) are supported.

## Cryptography Provider Manager

### Block Encryption Mode Constants

---

APF_SIGN	Message signing operations (including sign info import and export) are supported.
APF_VERIFY	Message verification operations (including verify info import and export) are supported.

---

## Block Encryption Mode Constants

**Purpose** The constants listed below represent the various block encryption modes that may be supported by an AP. You can request a particular mode by setting the [APCipherInfoStruct](#).mode field before passing the structure to the [CPMLibEncrypt\(\)](#) or [CPMLibDecrypt\(\)](#) function. If you don't specify a mode, the AP will choose one for you, and reset the mode field to the chosen mode.

The APMoDeEnum data type is used to type the encryption mode constants.

**Prototype** `typedef UInt32 APMoDeEnum;`

Note that encryption modes apply to block operations only. Specifying a mode for a stream encryption (through [CPMLibEncryptInit\(\)](#) *et al.*) has no effect.

The constants (and the type) are declared in CPMLibConstants.h. The constants are:

<code>apMoDeTypeUnspecified = 0</code>	The mode isn't specified; the AP uses its default mode.
<code>apMoDeTypeNone</code>	The encryption mode doesn't apply.
<code>apMoDeTypeECB</code>	Electronic codebook mode.
<code>apMoDeTypeCBC</code>	Cipher block chaining mode.
<code>apMoDeTypeCBC_CTS</code>	Cipher block chaining with cipher text stealing.

---

<code>apModeTypeCFB</code>	Cipher feedback mode.
<code>apModeTypeOFB</code>	Output feedback mode.
<code>apModeCounter</code>	Counter mode

---

## Cipher Algorithm Constants

**Purpose** These constants represent the different cipher algorithms that an AP may support. The algorithm type is encoded in the `type` field of the [APKeyInfoStruct](#) structure. You can request a specific algorithm by setting the value of the `type` field before passing the structure to [CPMLibGenerateKey\(\)](#). If you don't care, leave the field zero'd (`apAlgorithmTypeUnspecified`); the function will set the field to tell you which algorithm was used.

In the [APKeyInfoStruct](#) structure, the constants are typed as `APAlgorithmEnum`:

**Prototype** `typedef UInt32 APAlgorithmEnum`

The constants (and the type) are defined in `CPMLibCommon.h`. There we see the usual "unspecified" constant:

---

<code>apAlgorithmTypeUnspecified = 0</code>	No algorithm specified; the AP will use its default.
---	--

---

The rest of the constants are divided into groups, below, and listed with very little additional explanation: The constants' names are reasonably self-documenting.

### Block Cipher Algorithms

```
apSymmetricTypeDES
apSymmetricTypeRC2
apSymmetricTypeRC4
apSymmetricTypeRC5
apSymmetricTypeRC6,
apSymmetricTypeDESX_XDX3 ("Strong" DES)
apSymmetricType3DES_EDE2
apSymmetricType3DES_EDE3
```

apAsymmetricTypeBlumGoldwasser,  
apAsymmetricTypeRabin,  
apAsymmetricTypeRW (Rabin-Williams),  
apAsymmetricTypeLUC, apAsymmetricTypeLUCELG,  
apAsymmetricTypeECDSA, apAsymmetricTypeECNR,  
apAsymmetricTypeECIES, apAsymmetricTypeECDHC,  
apAsymmetricTypeECMQVC

#### **Key Agreement Ciphers**

apKeyAgreementTypeDH (Diffie-Hellman),  
apKeyAgreementTypeDH2 (Unified Diffie-Hellman),  
apKeyAgreementTypeMQV (Menezes-Qu-Vanstone),  
apKeyAgreementTypeLUCDIF, apKeyAgreementTypeXTRDH

## Export Encoding Constants

Constants that represent different data encoding schemes that are used to convert the crypto-info structs ([APKeyInfoStruct](#), [APHashInfoStruct](#), et al.) into a form that can be cached.

The encoding formats are used by the import and export functions, [CPMLibImportKeyInfo\(\)](#), [CPMLibExportKeyInfo\(\)](#), [CPMLibImportHashInfo\(\)](#), [CPMLibExportHashInfo\(\)](#), [CPMLibImportVerifyInfo\(\)](#), [CPMLibExportVerifyInfo\(\)](#), [CPMLibImportCipherInfo\(\)](#), and [CPMLibExportCipherInfo\(\)](#).

Declared in `CPMLibCommon.h`, the constants are:

---

<code>IMPORT_EXPORT_TYPE_RAW</code>	The default encoding, as defined by the AP.
<code>IMPORT_EXPORT_TYPE_DER</code>	ASN.1 DER encoding.
<code>IMPORT_EXPORT_TYPE_XML</code>	Standardized XML encoding.

---

## Hashing Algorithm Constants

The hashing constants represent various hashing algorithms. If you want to tell the AP to use a specific algorithm in a hashing operation, you would pass one of these constants as an argument to [CPMLibHash\(\)](#) or [CPMLibHashInit\(\)](#). If you want the default, use `apHashTypeUnspecified`. The algorithm that's actually used is returned through a [APHashInfoStruct](#) structure.

Declared in `CPMLibCommon.h`, the constants are:

## Cryptography Provider Manager

### Key Class Constants

---

<code>apHashTypeUnspecified = 0</code>	Unspecified hash algorithm; when generating a message digest, the AP decides which algorithm to use.
<code>apHashTypeNone</code>	Don't hash. Use this constant if you want the AP to suppress hashing in an operation, such as verification, that normally performs it
<code>apHashTypeMD2</code>	Rivest Message Digest 2 (MD2)
<code>apHashTypeMD5</code>	Rivest Message Digest 5 (MD5)
<code>apHashTypeSHA1</code>	Secure Hash Algorithm-160 (SHA-1)
<code>apHashTypeSHA256</code>	SHA 256-bit algorithm
<code>apHashTypeSHA384</code>	SHA 384-bit algorithm
<code>apHashTypeSHA512</code>	SHA 512-bit algorithm
<code>apHashTypeHAVAL</code>	HAVAL one-way algorithm
<code>apHashTypeRIPEMD160</code>	RIPEMD 160-bit
<code>apHashTypeTiger</code>	Tiger algorithm
<code>apHashTypePanama</code>	PANAMA algorithm

## Key Class Constants

**Purpose** A key's "class" specifies whether the key is symmetric or asymmetric and, if the latter, whether it's public or private. The key class constants represent these qualities. Key class is encoded in the `keyclass` field of the [APKeyInfoStruct](#) structure.

In the struct, the constants are typed as `APKeyClassEnum`:

**Prototype**    `typedef UInt32 APKeyClassEnum;`  
The constants (and the type) are defined in `CPMLibCommon.h`. The constants are:

---

<code>apKeyClassUnspecified = 0</code>	The key's class is unspecified.
<code>apKeyClassSymmetric</code>	This is a symmetric key.
<code>apKeyClassPublic</code>	This is the public part of an asymmetric key.
<code>apKeyClassPrivate</code>	This is the private part of an asymmetric key.

---

## Key Usage Constants

---

**Purpose**    **NOTE:** The key usage constants are currently unused.

---

The key usage constants describe the different ways that an encryption key can be used. How a key is used is encoded in the usage field of the key's [APKeyInfoStruct](#) structure.

Note that the key usage values are mutually exclusive; you can't OR a set of key usage constants to create a "selectively talented" key. The `apKeyUsageAll` constant is the only "multi-purpose" value currently provided.

The `APKeyUsageEnum` data type is used to type the key usage constants:

**Prototype**    `typedef UInt32 APKeyUsageEnum;`  
The constants (and the type) are defined in `CPMLibConstants.h`. The constants are:

---

<code>apKeyUsageUnspecified = 0</code>	The key's usage is unspecified.
<code>apKeyUsageAll</code>	The key can be used in any operation.

---

## Cryptography Provider Manager

### Plaintext Padding Constants

---

<code>apKeyUsageCertificateSigning</code>	The key is intended for certificate signing.
<code>apKeyUsageSigning</code>	The key is intended for message signing operations.
<code>apKeyUsageEncryption</code>	The key is intended for key or data encryption operations.
<code>apKeyUsageKeyEncrypting</code>	The key is intended for key encryption operations.
<code>apKeyUsageDataEncrypting</code>	The key is intended for data encryption operations.
<code>apKeyUsageMessageIntegrity</code>	The key is intended for message verification operations.

## Plaintext Padding Constants

**Purpose** The plaintext padding constants describe the different ways that plaintext is padded before it's encrypted. The padding type is encoded in the padding field of an [APCipherInfoStruct](#) structure.

The `APPaddingEnum` data type is used to type the padding constants:

**Prototype** `typedef UInt32 APPaddingEnum;`

The constants (and the type) are declared in `CPMLibCommon.h`. The constants are:

---

<code>apPaddingTypeUnspecified = 0</code>	The padding is unspecified; the AP will use the default
<code>apPaddingTypeNone</code>	Specifically request that padding <i>not</i> be applied.
<code>apPaddingTypePKCS1Type1</code>	Public Key Cryptography Standard 1, type 1
<code>apPaddingTypePKCS1Type2</code>	Public Key Cryptography Standard 1, type 2
<code>apPaddingTypePKCS5</code>	Public Key Cryptography Standard 5
<code>apPaddingTypeOAEP</code>	Optimal Asymmetric Encryption Padding
<code>apPaddingTypeSSLv23</code>	Secure Sockets Layer version 23

---

## CPM and AP Structures and Data Types

### APCipherInfoStruct Struct

**Purpose** The `APCipherInfoStruct` encapsulates information about an instance of a data encryption or decryption operation. The structure is populated and returned by the data encryption and decryption functions ([CPMLibEncrypt\(\)](#), [CPMLibDecrypt\(\)](#), [CPMLibEncryptInit\(\)](#), and [CPMLibDecryptInit\(\)](#)). You can set some of the fields' values yourself (before calling an encryption/decryption function) to fine-tune the impending operation.

You're responsible for allocating and freeing the `APCipherInfoStructs` that you need—the CPM never allocates them for you. The `APCipherInfoStructs` that you create (and

## Cryptography Provider Manager

### *APCipherInfoStruct*

---

actually use) must be released through [CPMLibReleaseCipherInfo\(\)](#) before they're freed.

For more information (including examples) on how to use a crypto-info structure, see "[Using the Crypto-Info Structures](#)."

Declared in `CPMLibCommon.h`, the structure looks like this:

**Prototype**

```
struct APCipherInfoStruct {
    APProviderContextType  providerContext;
    APAlgorithmEnum  type;
    APPaddingEnum  padding;
    UInt8  *iv;
    UInt32  ivLength;
    void  *algorithmParams;
};
```

The fields are:

---

<code>providerContext</code>	Information about the AP that performed (or is requested to perform) the operation. See <a href="#">APProviderContextStruct</a> .
<code>type</code>	Constant that represents the cipher algorithm that was used or that's requested. See <a href="#">Cipher Algorithm Constants</a>
<code>padding</code>	Constant that represents the plaintext padding scheme used by the algorithm. See <a href="#">Plaintext Padding Constants</a> .
<code>iv</code>	Initialization vector.
<code>ivLength</code>	The length of the initialization vector, in bytes.
<code>algorithmParams</code>	Additional data that's fed to the algorithm, as specified by the AP.

---

## APHashInfoStruct Struct

**Purpose** The APHashInfoStruct contains information about an instance of a message digest operation. You allocate the structure yourself, zero its contents, set the fields that you're interested in (if any), and then pass it as an argument to the message digest functions ([CPMLibHash\(\)](#), [CPMLibHashInit\(\)](#), [CPMLibExportHashInfo\(\)](#), and so on). When you're finished with the struct, you pass it to [CPMLibReleaseHashInfo\(\)](#).

For more information (including examples) on how to use the structure, see "[Using the Crypto-Info Structures](#)."

Declared in CPMLibCommon.h, the structure looks like this:

**Prototype**

```
struct APHashInfoStruct {
    AProviderContextType providerContext;
    APHashEnum type;
    UInt32 length;
};
```

The fields are:

providerContext	Information about the AP that performed (or is requested to perform) the operation. See <a href="#">AProviderContextStruct</a> .
type	The hashing algorithm that was used to create (or is requested to create) the message digest.
length	The length of the digest.

The APHashInfoStruct is one of the crypto-info structures; it's used as an input/output argument to the message digest functions ([CPMLibHash\(\)](#), [CPMLibHashInit\(\)](#), [CPMLibExportHashInfo\(\)](#), and so on). You allocate the structure yourself; before passing the struct to a function, you *must* zero its contents. When you're finished with the struct, you pass it to [CPMLibReleaseHashInfo\(\)](#). For more information on how to use a crypto-info structure, see "[Using the Crypto-Info Structures](#)."

## APKeyInfoStruct Struct

**Purpose** The APKeyInfoStruct holds information about an encryption key.

**Prototype**

```
struct APKeyInfoStruct {
    APProviderContextType  providerContext;
    APAlgorithmEnum  type;
    APKeyUsageEnum  usage;
    APKeyClassEnum  keyclass;
    UInt32  length;
    UInt32  actualLength;
    UInt16  exportable;
    UInt16  ephemeral;
};
```

providerID	Algorithm provider ID number.
type	A code that identifies the type of algorithm, one of the <a href="#">Cipher Algorithm Constants</a> values.
usage	A code that identifies how the algorithm is used, one of the <a href="#">Key Usage Constants</a> values.
keyLength	Length of the key data, in bytes and padded to the next largest word. (Default is 8.)
keyActualLength	The actual, unpadded length of the key data. (Default is 7).
exportable	Can this key be used in a CPMSExportKey() call?. 1 if it can, 0 if it can't.
ephemeral	Is this a "one-shot" key? 1 if it is, 0 if it's permanent..

## APProviderContextStruct Struct

**Purpose** The APProviderContextStruct contains information about an instance of a cryptographic operation. The structure is contained (as an APProviderContextType value) in the four crypto-info structs, [APKeyInfoStruct](#), [APHashInfoStruct](#), [APCipherInfoStruct](#), and [APVerifyInfoStruct](#).

Declared in `CPMLibCommon.h`, the structure looks like this:

**Prototype**    `struct APPProviderContextStruct {  
                  UInt32  providerID;  
                  void  *localContext;  
};`

The fields are

---

providerID	Integer that uniquely identifies the provider that's being used in the operation.
localContext	Provider-specific information about the operation.

---

## APPProviderInfoStruct Struct

**Purpose**    The `APPProviderInfoStruct` contains information about a specific algorithm provider. The structure is returned (as an `APPProviderInfoType`) by [CPMLibGetProviderInfo\(\)](#).

Declared in `CPMLibCommon.h`, the structure looks like this:

**Prototype**    `struct APPProviderInfoStruct {  
                  char  name[32];  
                  char  other[64];  
                  UInt32  flags;  
                  UInt8  numAlgorithms;  
                  Boolean  bHardware;  
};`

The fields are:

---

name	The human-readable name of the provider.
other	Additional textual information.

flags	A bitfield that publishes the functionality that this provider supports. See <a href="#">AP Capability Constants</a> for a list of values that this field can combine.
numAlgorithms	A count of the algorithms this provider supplies.
bHardware	true if the provider's algorithms are implemented in hardware; false if in software.

## APVerifyInfoStruct Struct

**Purpose** The `APVerifyInfoStruct` is used by the verification functions ([CPMLibVerify\(\)](#), *et al.*) to verify a message. It contains (primarily) the hash operation and cipher operation information that will be used during verification. It's the caller's responsibility to allocate and embed the structure's `APHashInfoStruct` and `APCipherInfoStruct` fields before passing the `APVerifyInfoStruct` to a verification function.

Any `APVerifyInfoStruct`s that you actually use must be released through [CPMLibReleaseVerifyInfo\(\)](#) before it's freed. The embedded structures must also be released through [CPMLibReleaseCipherInfo\(\)](#) and [CPMLibReleaseHashInfo\(\)](#).

For more information (including examples) on how to use a crypto-info structure, see "[Using the Crypto-Info Structures](#)."

Declared in `CPMLibCommon.h`, the structure looks like this:

**Prototype**

```
struct APVerifyInfoStruct {
    APProviderContextType  providerContext;
    APHashInfoType        *hashInfoP;
    APCipherInfoType       *cipherInfoP;
}
```

The fields are:

---

providerContext	Information about the AP that performed (or is requested to perform) the operation. See <a href="#">APProviderContextStruct</a> .
hashInfoP	<a href="#">APHashInfoStruct</a> that contains the certificate's hash information.
cipherInfoP	<a href="#">APCipherInfoStruct</a> that contains the certificate's cipher information.

---

## CPMInfoStruct Struct

**Purpose** Structure that provides information about the CPM library. It's used by the [CPMLibGetInfo\(\)](#) function.

**Prototype**

```
typedef struct CPMInfoStruct {
    UInt8    numInstances;
    UInt8    numProviders;
    Boolean   defaultProviderPresent;
};
```

The fields are:

---

numInstances	The number of clients (applications) that are talking to this library.
numProviders	The number of algorithm providers that this library knows about.
defaultProviderPresent	Does the library contain a default provider? <code>true</code> if it does, otherwise <code>false</code> .

---

## CPM Functions

### CPMLibDecrypt Function

<b>Purpose</b>	Decrypts a block of encrypted data.
<b>Declared In</b>	CPMLib68kInterface.h, CPMLibARMInterface.h
<b>Prototype</b>	<pre>Err CPMLibDecrypt ( UInt16 libRef,     APKeyInfoType *keyInfo,     APCipherInfoType *cipherInfo, UInt8 *inBuffer,     UInt32 inBufferLength, UInt8 *outBuffer,     UInt32 *outBufferLength )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) CPM Library reference number.</p> <p>→ <i>keyInfo</i> <a href="#">APKeyInfoStruct</a> that contains the key that was used to encrypt the data. You obtain the structure by importing the <a href="#">APKeyInfoStruct</a> that was exported by the data encryptor.</p> <p>↔ <i>cipherInfo</i> A pointer to an <a href="#">APCipherInfoStruct</a> that describes the parameters that will be used in the decryption operation. You typically retrieve the structure by importing the <a href="#">APCipherInfoStruct</a> that was exported by the data encryptor. If you're using the decryption defaults provided by the CPM library, you can pass in a freshly allocated (and zero'd) <a href="#">APCipherInfoStruct</a>; in this case, the structure will be populated by this function to reflect the actual decryption parameters.</p> <p>→ <i>inBuffer</i> A pointer to the (encrypted) data that you want to decrypt.</p> <p>→ <i>inBufferLength</i> Length, in bytes, of <i>inBuffer</i>.</p> <p>← <i>outBuffer</i> A pointer to the buffer into which the decrypted data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data.</p>

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns *cpmErrBufTooSmall*, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the decrypted data..

**Returns** The function returns *errNone* upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This functions performs block decryption. For stream decryption, see [CPMLibDecryptInit\(\)](#).

The *keyInfo* and *cipherInfo* must agree on the algorithm type, as specified in their respective *APAlgorithmEnum* fields.

If *outBuffer* isn't big enough, the function will fail and *outBufferLength* will return the "correct" output buffer size (i.e. large enough to accommodate the encrypted data) . When this happens, simply reallocate the output buffer and call *CPMLibDecrypt* again.

## CPMLibDecryptFinal Function

**Purpose** Finalizes a stream decryption operation.

**Declared In** *CPMLib68kInterface.h*, *CPMLibARMInterface.h*

**Prototype**

```
Err CPMLibDecryptFinal ( UInt16 libRef,
    APKeyInfoType *keyInfo,
    APCipherInfoType *cipherInfo, UInt8 *inBuffer,
    UInt32 inBufferLength, UInt8 *outBuffer,
    UInt32 *outBufferLength)
```

**Parameters** → *libRef*  
 CPM Library reference number (68k only).

→ *keyInfo*  
 Key used to decrypt the data, as returned by [CPMLibGenerateKey\(\)](#) or [CPMLibImportKeyInfo\(\)](#).

→ *cipherInfo*  
 A pointer to the [APCipherInfoStruct](#) that was returned by the stream-initializing [CPMLibDecryptInit\(\)](#) call.

## Cryptography Provider Manager

### *CPMLibDecryptFinal*

---

→ *inBuffer*

A pointer to the data that you want to encrypt. If you already supplied all the data through previous [CPMLibDecryptUpdate\(\)](#) calls, pass NULL.

→ *inBufferLength*

The length of *inBuffer*, in bytes. If *inBuffer* is NULL, pass 0.

← *outBuffer*

A pointer to the buffer where the decrypted *inBuffer* data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data.

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns `cpmErrBufTooSmall`, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the decrypted *inBuffer* data..

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function (optionally) decrypts a final buffer of data and then closes the decryption stream that was initialized by [CPMLibDecryptInit\(\)](#).

Note that *outBuffer* contains the decrypted *inBuffer* data only—it doesn't contain all the data that was decrypted by this stream. It's the callers responsibility to accumulate the data that was decrypted by previous, successive [CPMLibDecryptUpdate\(\)](#) calls.

## CPMLibDecryptInit Function

<b>Purpose</b>	Initializes a stream decryption session.
<b>Declared In</b>	CPMLib68kInterface.h, CPMLibARMInterface.h
<b>Prototype</b>	<pre>Err CPMLibDecryptInit ( UInt16 libRef,                         APKeyInfoType *keyInfo,                         APCipherInfoType *cipherInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>keyInfo</i> <a href="#">APKeyInfoStruct</a> that contains the key that was used to encrypt the data. You obtain the structure by importing the <a href="#">APKeyInfoStruct</a> that was exported by the data encryptor.</p> <p>↔ <i>cipherInfo</i> A pointer to an <a href="#">APCipherInfoStruct</a> that describes the parameters that will be used in the decryption operation. You typically retrieve the structure by importing the <a href="#">APCipherInfoStruct</a> that was exported by the data encryptor. If you're using the decryption defaults provided by the CPM library, you can pass in a freshly allocated (and zero'd) <a href="#">APCipherInfoStruct</a>; in this case, the structure will be populated by this function to reflect the actual decryption parameters.</p>
<b>Returns</b>	The function returns <code>errNone</code> upon success. For other error codes, see <a href="#">CPM Error Codes</a> .
<b>Comments</b>	<p>This function initializes a stream decryption operation. To feed data to the operation, you call <a href="#">CPMLibDecryptUpdate()</a> followed by <a href="#">CPMLibDecryptFinal()</a>. The “update” function is optional; the “final” function is mandatory. For block encryption, see <a href="#">CPMLibDecrypt()</a>.</p> <p>The <i>keyInfo</i> and <i>cipherInfo</i> must agree on the algorithm type, as specified in their respective <code>APAlgorithmEnum</code> fields.</p>

## CPMLibDecryptUpdate Function

- Purpose** Feeds data to a stream decryption operation.
- Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h
- Prototype**

```
Err CPMLibDecryptUpdate ( UInt16 libRef,
    APKeyInfoType *keyInfo,
    APCipherInfoType *cipherInfo, UInt8 *inBuffer,
    UInt32 inBufferLength, UInt8 *outBuffer,
    UInt32 *outBufferLength)
```
- Parameters** see [CPMLibEncryptFinal\(\)](#)
- Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).
- Comments** This function feeds data into the stream decryption session that was started by [CPMLibDecryptInit\(\)](#). You can make any number of `CPMLibDecryptUpdate` calls while the stream is open. When you've finished feeding data into the stream, you call [CPMLibDecryptFinal\(\)](#).
- This function's arguments, return values, and behavior are nearly identical to [CPMLibDecryptFinal\(\)](#) (which see for details). The only difference between them is that this function leaves the stream open, and [CPMLibDecryptFinal\(\)](#) closes it.

## CPMLibEncrypt Function

- Purpose** Encrypts a block of data.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibEncrypt ( UInt16 libRef,
    APKeyInfoType *keyInfo,
    APCipherInfoType *cipherInfo, UInt8 *inBuffer,
    UInt32 inBufferLength, UInt8 *outBuffer,
    UInt32 *outBufferLength)
```
- Parameters**   
→ *libRef*  
CPM Library reference number (68k only).  
→ *keyInfo*  
A pointer to an [APKeyInfoStruct](#) that represents the key that will be used to encrypt the data. The allocate the

structure, zero it, and then populate it by calling [CPMLibGenerateKey\(\)](#) or [CPMLibImportKeyInfo\(\)](#).

→ *cipherInfo*

A pointer to an [APCipherInfoStruct](#) that you can use to set the parameters of the encryption operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default cipher settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.

→ *inBuffer*

A pointer to the data that you want to encrypt.

→ *inBufferLength*

The length of *inBuffer*, in bytes.

← *outBuffer*

A pointer to the buffer where the encrypted data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the encrypted data.

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns `cpmErrBufTooSmall`, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the encrypted data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This functions performs block encryption. For stream encryption, see [CPMLibEncryptInit\(\)](#).

The *keyInfo* and *cipherInfo* must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

If *outBuffer* isn't big enough, the function will fail and *outBufferLength* will return the "correct" output buffer size (i.e. large enough to accommodate the encrypted data) . When this happens, simply reallocate the output buffer and call `CPMLibEncrypt` again.

After you've encrypted the data, you must export the `keyInfo` and `cipherInfo` structures (see [CPMLibExportKeyInfo\(\)](#) and [CPMLibExportCipherInfo\(\)](#)) so they can be imported, later, by the data decryptor. Secure storage and transmission of the encryption key is th caller's responsibility.

To decrypt encrypted data, you call [CPMLibDecrypt\(\)](#) or [CPMLibDecryptInit\(\)](#).

## CPMLibEncryptFinal Function

<b>Purpose</b>	Finalizes a stream encryption operation.
<b>Declared In</b>	CPMLib68kInterface.h, CPMLibARMInterface.h
<b>Prototype</b>	<pre>Err CPMLibEncryptFinal ( UInt16 libRef,     APKeyInfoType *keyInfo,     APCipherInfoType *cipherInfo, UInt8 *inBuffer,     UInt32 inBufferLength, UInt8 *outBuffer,     UInt32 *outBufferLength)</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>keyInfo</i> Key used to encrypt the data, as returned by <a href="#">CPMLibGenerateKey()</a> or <a href="#">CPMLibImportKeyInfo()</a>.</p> <p>→ <i>cipherInfo</i> A pointer to the <a href="#">APCipherInfoStruct</a> that was returned in the stream-initializing <a href="#">CPMLibEncryptInit()</a> call.</p> <p>→ <i>inBuffer</i> A pointer to the data that you want to encrypt. If you already supplied all the data through previous <a href="#">CPMLibEncryptUpdate()</a> calls, pass NULL.</p> <p>→ <i>inBufferLength</i> The length of <i>inBuffer</i>, in bytes. If <i>inBuffer</i> is NULL, pass 0.</p> <p>← <i>outBuffer</i> A pointer to the buffer where the encrypted <i>inBuffer</i> data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate the encrypted <i>inBuffer</i> data.</p>

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns *cpmErrBufTooSmall*, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the encrypted data.

**Returns** The function returns *errNone* upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function (optionally) encrypts a final buffer of data and then closes the encryption stream that was initialized by [CPMLibEncryptInit\(\)](#).

After you've encrypted the data, you should export the *keyInfo* and *cipherInfo* structures (see [CPMLibExportKeyInfo\(\)](#) and [CPMLibExportCipherInfo\(\)](#)) so they can be imported, later, by the data decryptor. Secure storage and transmission of the encryption key is the caller's responsibility.

Note that *outBuffer* contains the encrypted *inBuffer* data only—it doesn't contain all the data that was encrypted by this stream. It's the callers responsibility to accumulate the data that was encrypted by previous, successive [CPMLibEncryptUpdate\(\)](#) calls.

To decrypt encrypted data, you call [CPMLibDecrypt\(\)](#) or [CPMLibDecryptInit\(\)](#).

## CPMLibEncryptInit Function

**Purpose** Initializes a stream encryption session.

**Declared In** *CPMLib68kInterface.h*, *CPMLibARMInterface.h*

**Prototype**

```
Err CPMLibEncryptInit ( UInt16 libRef,
                        APKeyInfoType *keyInfo,
                        APCipherInfoType *cipherInfo )
```

**Parameters** → *libRef*  
CPM Library reference number (68k only).

## Cryptography Provider Manager

### CPMLibEncryptUpdate

---

→ *keyInfo*

Key used to encrypt the data, as returned by [CPMLibGenerateKey\(\)](#) or [CPMLibImportKeyInfo\(\)](#).

→ *cipherInfo*

A pointer to an [APCipherInfoStruct](#) that you can use to set the parameters of the encryption operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default cipher settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation. The structure is used as a cookie in the subsequent [CPMLibEncryptUpdate\(\)](#) and/or [CPMLibEncryptFinal\(\)](#) functions.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function initializes a stream encryption operation. To feed data to the operation, you call [CPMLibEncryptUpdate\(\)](#) followed by [CPMLibEncryptFinal\(\)](#). The “update” function is optional; the “final” function is mandatory. For block encryption, see [CPMLibEncrypt\(\)](#).

The *keyInfo* and *cipherInfo* must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

To decrypt encrypted data, you call [CPMLibDecrypt\(\)](#) or [CPMLibDecryptInit\(\)](#).

## CPMLibEncryptUpdate Function

**Purpose** Feeds data to a stream encryption operation.

**Declared In** `CPMLib68kInterface.h`, `CPMLibARMInterface.h`

**Prototype**

```
Err CPMLibEncryptUpdate ( UInt16 libRef,
                          APKeyInfoType *keyInfo,
                          APCipherInfoType *cipherInfo, UInt8 *inBuffer,
                          UInt32 inBufferLength, UInt8 *outBuffer,
                          UInt32 *outBufferLength)
```

**Parameters** see [CPMLibEncryptFinal\(\)](#)

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds data into the stream encryption session that was started by [CPMLibEncryptInit\(\)](#). You can make any number of [CPMLibEncryptUpdate](#) calls while the encryption stream is open. When you've finished feeding data into the stream, you call [CPMLibEncryptFinal\(\)](#).

This function's arguments, return values, and behavior are nearly identical to [CPMLibEncryptFinal\(\)](#) (which see for details). The only difference between them is that this function leaves the stream open, and [CPMLibEncryptFinal\(\)](#) closes it.

## CPMLibExportCipherInfo Function

**Purpose** Encodes a cipher into a form that can be cached. To reconstitute an exported cipher, pass it to [CPMLibImportCipherInfo\(\)](#).

**Declared In** [CPMLib68KInterface.h](#), [CPMLibArmInterface.h](#)

**Prototype**

```
Err CPMLibExportCipherInfo ( UInt16 libRef,
    APCipherInfoType *cipherInfo, UInt8 encoding,
    UInt8 *exportBuffer,
    UInt32 exportBufferLength )
```

**Parameters**

- *libRef*  
CPM Library reference number (68k only).
- *cipherInfo*  
Structure that represents the cipher that you want to export, as created and returned by [CPMLibGenerateKey\(\)](#), or as imported through [CPMLibImportKeyInfo\(\)](#).
- *encoding*  
Constant that specifies the type of encoding. One of [IMPORT\\_EXPORT\\_RAW](#), [IMPORT\\_EXPORT\\_DER](#), or [IMPORT\\_EXPORT\\_XML](#). See [Export Encoding Constants](#) for details about these formats.
- ↔ *exportBuffer*  
Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to NULL if you're using the function to retrieve the size of the encoded data.

## Cryptography Provider Manager

### CPMLibExportHashInfo

---

↔ *exportBufferLength*

You pass in the size of `exportBuffer` in bytes. The function returns (through this argument) the size that's required to accommodate the encoded data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the required `exportBuffer`, and then again (after allocating the buffer) to get the encoded buffer. See "[Using the Export Functions](#)" for more information and a free sample.

## CPMLibExportHashInfo Function

**Purpose** Encodes an [APHashInfoStruct](#) into a form that can be cached. To reconstitute an exported hash info, pass it to [CPMLibImportHashInfo\(\)](#).

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibExportKeyInfo ( UInt16 libRef,  
APHashInfoType *hashInfo, UInt8 encoding,  
UInt8 *exportBuffer,  
UInt32 exportBufferLength )`

**Parameters** → *libRef*  
CPM Library reference number (68k only).

→ *hashInfo*  
Structure that you want to export.

→ *encoding*  
Constant that specifies the type of encoding. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.

↔ *exportBuffer*  
Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to `NULL` if you're using the function to retrieve the size of the encoded data (see below)

↔ *exportBufferLength*

You pass in the size of `exportBuffer` in bytes; the function returns (through this argument) the size that's required to accommodate the encoded data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the export buffer, and then again (after allocating the buffer) to retrieve the encoded data. See "[Using the Export Functions](#)" for more information and a free sample.

## CPMLibExportKeyInfo Function

**Purpose** Encodes a [APKeyInfoStruct](#) into a form that can be cached. To reconstitute an exported key, pass it to [CPMLibImportKeyInfo\(\)](#).

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibExportKeyInfo ( UInt16 libRef,
                          APKeyInfoType *keyInfo, UInt8 encoding,
                          UInt8 *exportBuffer,
                          UInt32 exportBufferLength )
```

**Parameters** → *libRef*  
CPM Library reference number (68k only).

→ *keyInfo*  
Structure that you want to export.

→ *encoding*  
Constant that specifies the type of encoding. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.

↔ *exportBuffer*  
Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to `NULL` if you're using the function to retrieve the size of the encoded data (see below)

## Cryptography Provider Manager

### CPMLibExportVerifyInfo

---

↔ *exportBufferLength*

You pass in the size of `exportBuffer` in bytes; the function returns (through this argument) the size that's required to accommodate the encoded data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the export buffer, and then again (after allocating the buffer) to retrieve the encoded data. See "[Using the Export Functions](#)" for more information and a free sample.

## CPMLibExportVerifyInfo Function

**Purpose** Encodes a [APVerifyInfoStruct](#) into a form that can be cached. To reconstitute an exported key, pass it to [CPMLibImportVerifyInfo\(\)](#).

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibExportKeyInfo ( UInt16 libRef,
    APVerifyInfoType *verifyInfo, UInt8 encoding,
    UInt8 *exportBuffer,
    UInt32 exportBufferLength )
```

**Parameters** → *libRef*  
CPM Library reference number (68k only).

→ *keyInfo*  
Structure that you want to export.

→ *encoding*  
Constant that specifies the type of encoding. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.

↔ *exportBuffer*  
Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to `NULL` if you're using the function to retrieve the size of the encoded data (see below)

↔ *exportBufferLength*

You pass in the size of `exportBuffer` in bytes; the function returns (through this argument) the size that's required to accommodate the encoded data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the export buffer, and then again (after allocating the buffer) to retrieve the encoded data. See "[Using the Export Functions](#)" for more information and a free sample.

## CPMLibGenerateKey Function

**Purpose** Generates a new symmetric key.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibGenerateKey ( UInt16 libRef,  
                          UInt8 *seedData, UInt32 seedLength,  
                          APKeyInfoType *keyInfo )`

**Parameters** → *libRef*  
CPM Library reference number (68k only).

→ *seedData*  
Optional data that's used to seed the key generator. Because PalmOS 5 doesn't currently support key "derivation" (identical key generation based on identical seeds) the seed data is, in essence, a no-op, and can be a pointer to 0. However, you may want to supply (and cache) unique seed data today in anticipation of tomorrow's derivation functionality.

→ *seedLength*  
Length of *seedData*, in bytes. (Pass 0 if *\*seedData* is 0.)

↔ *keyInfo*  
A pointer to a [APKeyInfoStruct](#) that will contain the generated key. The `keyInfo` structure is allocated and owned by the caller. You can specify the desired provider, key-generation scheme, and so on, by setting the `APKeyInfoType` fields. Or, to retrieve a default key, zero the structure before you pass it in.

## Cryptography Provider Manager

### *CPMLibGetInfo*

---

- Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).
- Comments** The [APKeyInfoStruct](#) that's populated by this function can be used in subsequent encryption, decryption, and verification operations.
- When you're finished using the [APKeyInfoStruct](#), you must release it through [CPMLibReleaseKeyInfo\(\)](#).

## CPMLibGetInfo Function

- Purpose** Retrieves information about the CPM library.
- Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`
- Prototype**

```
Err CPMLibLibGetInfo ( UInt16 libRef,
                      CPMInfoType *info)
```
- Parameters**
- *libRef*  
CPM Library reference number (68k only).
  - *info*  
Pointer to a [CPMInfoStruct](#) that returns the information about the library. See [CPMInfoStruct](#) for a description.
- Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibGetProviderInfo Function

- Purpose** Retrieves information about a specific provider.
- Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`
- Prototype**

```
Err CPMLibGetProviderInfo ( UInt16 libRef,
                             UInt32 providerID,
                             APPProviderInfoType *providerInfo)
```
- Parameters**
- *libRef*  
CPM Library reference number (68k only).
  - *providerID*  
ID number that identifies the provider.

← *providerInfo*

Structure into which the function places provider information. The structure is allocated and freed by the caller. The function doesn't clear inapplicable fields on the way out.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibHash Function

**Purpose** Hashes a block of data.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibHash ( UInt16 libRef, AHashEnum type, AHashInfoType *hashInfo, UInt8 *inBuffer, UInt32 inBufferLength, UInt8 *outBuffer, UInt32 *outBufferLength )`

**Parameters**

- *libRef*  
CPM Library reference number (68k only).
- *type*  
A constant that represents the hashing algorithm that will be used to create the message digest. See [Hashing Algorithm Constants](#) for a list of constants. If you want the default algorithm, use `apHashTypeUnspecified`.
- *hashInfo*  
A pointer to an [AHashInfoStruct](#) that you can use to set the parameters of the hashing operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.
- *inBuffer*  
A pointer to the data that you want to hash.
- *inBufferLength*  
The length of `inBuffer`, in bytes. If `inBuffer` is `NULL`, pass 0.

← *outBuffer*

A pointer to the buffer where the hashed *inBuffer* data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the hashed data.

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns `cpmErrBufTooSmall`, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the hashed data..

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function performs a block hash operation. For stream hashing, use [CPMLibHashInit\(\)](#).

## CPMLibHashFinal Function

**Purpose** Finalizes a hash session and returns the hashed data.

**Declared In** `CPMLib.h`

**Prototype**

```
Err CPMLibHashFinal ( UInt16 libRef,  
    AHashInfoType *hashInfo, UInt8 *inBuffer,  
    UInt32 inBufferLength, UInt8 *outBuffer,  
    UInt32 *outBufferLength )
```

**Parameters**

- *libRef*  
CPM Library reference number (68k only).
- *hashInfo*  
A pointer to the [AHashInfoStruct](#) that was returned by [CPMLibHashInit\(\)](#).
- *inBuffer*  
A pointer to the data that you want to hash. If you already supplied all the data through previous [CPMLibHashUpdate\(\)](#) calls, pass `NULL`.
- *inBufferLength*  
The length of *inBuffer*, in bytes. If *inBuffer* is `NULL`, pass 0.

← *outBuffer*

A pointer to the buffer where all the data that has been hashed by this stream will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the hashed data.

↔ *outBufferLength*

You pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns `cpmErrBufTooSmall`, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the hashed data.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function returns all the data that was hashed by the hash stream, and then closes the stream. It follows an initial call to [CPMLibHashInit\(\)](#) and some number of calls to [CPMLibHashUpdate\(\)](#).

## CPMLibHashInit Function

**Purpose** Initiates a streaming hash operation.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibHash ( UInt16 libRef,  
APHashInfoType *hashInfo )`

**Parameters** → *libRef*

CPM Library reference number (68k only).

→ *hashInfo*

A pointer to an [APHashInfoStruct](#) that you can use to set the parameters of the hash operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function initializes a streaming hash operation. To feed data to the stream, you call [CPMLibHashUpdate\(\)](#) followed by [CPMLibHashFinal\(\)](#). The “update” function is optional; the “final” function is mandatory. For a block hash, see [CPMLibHash\(\)](#).

## CPMLibHashUpdate Function

**Purpose** Sends data to streaming hash operation.

**Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype** Err CPMLibHashUpdate ( UInt16 libRef,  
APHashInfoType \*hashInfo, UInt8 \*inBuffer,  
UInt32 inBufferLength)

**Parameters**

- *libRef*  
CPM Library reference number (68k only).
- *hashInfo*  
A pointer to the [APHashInfoStruct](#) that was returned by [CPMLibHashInit\(\)](#).
- *inBuffer*  
A pointer to the data that you want to hash.
- *inBufferLength*  
The length of *inBuffer*, in bytes.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds data into the streaming hash session that was started by [CPMLibHashInit\(\)](#). You can make any number of `CPMLibHashUpdate` calls while the hash stream is open. When you’ve finished feeding data into the stream, you call [CPMLibHashFinal\(\)](#).

Note that this function doesn’t return any hashed data. All the data that’s hashed by the stream is returned through the [CPMLibHashFinal\(\)](#) call.

## CPMLibImportCipherInfo Function

<b>Purpose</b>	Imports a previously-exported cipher info structure so that it can be used in subsequent operations.
<b>Declared In</b>	CPMLib68KInterface.h, CPMLibArmInterface.h
<b>Prototype</b>	<pre>Err CPMLibImportCipherInfo ( UInt16 libRef,                              UInt8 encoding, UInt8 *importData,                              UInt32 importDataLength,                              APCipherInfoType *cipherInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>encoding</i> Constant that specifies the encoding type that was used to export the key. One of IMPORT_EXPORT_RAW, IMPORT_EXPORT_DER, or IMPORT_EXPORT_XML. See <a href="#">Export Encoding Constants</a> for details about these formats.</p> <p>→ <i>importData</i> The encoded data.</p> <p>→ <i>importDataLength</i> The length of importData, in bytes.</p> <p>← <i>cipherInfo</i> <a href="#">APCipherInfoStruct</a> that returns the imported key. The structure must be allocated before it's passed in.</p>
<b>Returns</b>	The function returns errNone upon success. For other error codes, see <a href="#">CPM Error Codes</a> .

## CPMLibImportHashInfo Function

<b>Purpose</b>	Imports a previously-exported hash info structure so that it can be used in subsequent operations.
<b>Declared In</b>	CPMLib68KInterface.h, CPMLibArmInterface.h
<b>Prototype</b>	<pre>Err CPMLibImportHashInfo ( UInt16 libRef,     UInt8 encoding, UInt8 *importData,     UInt32 importDataLength,     AHashInfoType *keyInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>encoding</i> Constant that specifies the encoding type that was used to export the key. One of IMPORT_EXPORT_RAW, IMPORT_EXPORT_DER, or IMPORT_EXPORT_XML. See <a href="#">Export Encoding Constants</a> for details about these formats.</p> <p>→ <i>importData</i> The encoded data.</p> <p>→ <i>importDataLength</i> The length of importData, in bytes.</p> <p>← <i>hashInfo</i> <a href="#">AHashInfoStruct</a> that returns the imported hash info. The structure must be allocated before it's passed in.</p>
<b>Returns</b>	The function returns errNone upon success. For other error codes, see <a href="#">CPM Error Codes</a> .

## CPMLibImportKeyInfo Function

<b>Purpose</b>	Imports a previously-exported key so that it (the key) can be used in subsequent operations.
<b>Declared In</b>	CPMLib68KInterface.h, CPMLibArmInterface.h
<b>Prototype</b>	<pre>Err CPMLibImportKeyInfo ( UInt16 libRef,                           UInt8 encoding, UInt8 *importData,                           UInt32 importDataLength,                           APKeyInfoType *keyInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>encoding</i> Constant that specifies the encoding type that was used to export the key. One of IMPORT_EXPORT_RAW, IMPORT_EXPORT_DER, or IMPORT_EXPORT_XML. See <a href="#">Export Encoding Constants</a> for details about these formats.</p> <p>→ <i>importData</i> The encoded data.</p> <p>→ <i>importDataLength</i> The length of importData, in bytes.</p> <p>← <i>keyInfo</i> <a href="#">APKeyInfoStruct</a> that returns the imported key. The structure must be allocated before it's passed in.</p>
<b>Returns</b>	The function returns errNone upon success. For other error codes, see <a href="#">CPM Error Codes</a> .

## CPMLibImportVerifyInfo Function

<b>Purpose</b>	Imports a previously-exported verify info structure so that it can be used in subsequent operations.
<b>Declared In</b>	CPMLib68KInterface.h, CPMLibArmInterface.h
<b>Prototype</b>	<pre>Err CPMLibImportVerifyInfo ( UInt16 libRef,     UInt8 encoding, UInt8 *importData,     UInt32 importDataLength,     APVerifyInfoType *keyInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>encoding</i> Constant that specifies the encoding type that was used to export the key. One of IMPORT_EXPORT_RAW, IMPORT_EXPORT_DER, or IMPORT_EXPORT_XML. See <a href="#">Export Encoding Constants</a> for details about these formats.</p> <p>→ <i>importData</i> The encoded data.</p> <p>→ <i>importDataLength</i> The length of importData, in bytes.</p> <p>← <i>verifyInfo</i> <a href="#">APVerifyInfoStruct</a> that returns the imported verify info. The structure must be allocated before it's passed in.</p>
<b>Returns</b>	The function returns errNone upon success. For other error codes, see <a href="#">CPM Error Codes</a> .

## CPMLibReleaseCipherInfo Function

<b>Purpose</b>	Releases a <a href="#">APCipherInfoStruct</a> , allowing you to free it.
<b>Declared In</b>	CPMLib68KInterface.h, CPMLibArmInterface.h
<b>Prototype</b>	<pre>Err CPMLibReleaseCipherInfo ( UInt16 libRef,     APCipherInfoType *cipherInfo )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p>

→ *cipherInfo*

A pointer to a [APCipherInfoStruct](#) that you want to release.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibReleaseHashInfo Function

**Purpose** Releases a [APKeyInfoStruct](#), allowing you to free it.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibReleaseHashInfo ( UInt16 libRef,  
APHashInfoType *hashInfo )`

**Parameters** → *libRef*

CPM Library reference number (68k only).

→ *hashInfo*

A pointer to a [APHashInfoStruct](#) that you want to release.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibReleaseKeyInfo Function

**Purpose** Releases a [APKeyInfoStruct](#), allowing you to free it.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibReleaseKeyInfo ( UInt16 libRef,  
APKeyInfoType *keyInfo )`

**Parameters** → *libRef*

CPM Library reference number (68k only).

→ *keyInfo*

A pointer to the [APKeyInfoStruct](#) that you want to release.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibReleaseVerifyInfo Function

- Purpose** Releases a [APVerifyInfoStruct](#), allowing you to free it.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibReleaseVerifyInfo ( UInt16 libRef,
                             APVerifyInfoType *verifyInfo )
```
- Parameters**
- *libRef*  
CPM Library reference number (68k only).
  - *verifyInfo*  
A pointer to a [APVerifyInfoStruct](#) that you want to release.
- Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

## CPMLibVerify Function

- Purpose** Verifies a message.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibVerify ( UInt16 libRef,
                   APKeyInfoType *keyInfo,
                   APVerifyInfoType *verifyInfo, UInt8 *inBuffer,
                   UInt32 inBufferLength, UInt8 *outBuffer,
                   UInt32 *outBufferLength, UInt8 *signature,
                   UInt32 signatureLength,
                   VerifyResultType *verifyResult )
```
- Parameters**
- *libRef*  
CPM Library reference number (68k only).
  - *keyInfo*  
An [APKeyInfoStruct](#) that represents the certificate's encryption key. Extracting the key data from the certificate and constructing the [APKeyInfoStruct](#) (through [CPMLibImportKeyInfo\(\)](#)) is the caller's responsibility.
  - *verifyInfo*  
A pointer to an [APVerifyInfoStruct](#) that specifies the hash and cipher operations that should be performed during verification. This information is embedded as [APHashInfoStruct](#) and [APCipherInfoStruct](#)

structures. If you want to use the default operations, allocate and zero the embedded structures. When the function returns, the structures will be populated with information describing the operations that were used.

→ *inBuffer*

A pointer to the message data.

→ *inBufferLength*

The length of *inBuffer*, in bytes.

← *outBuffer*

A pointer to the buffer where the decrypted signature will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data. If you don't care about the signature, pass `NULL`.

↔ *outBufferLength*

If *outBuffer* is `NULL`, set this to 0. Otherwise, you pass in the (allocated) length of *outBuffer*, in bytes. The function resets the argument to the amount of data that was actually copied into *outBuffer*. If the function returns `cpmErrBufTooSmall`, *outBufferLength* is set to the minimum buffer size that's needed to accommodate the verified data.

→ *signature*

A pointer to the message's signature. Extracting the signature from the message is the caller's responsibility

→ *signatureLength*

The length of the signature, in bytes.

← *verifyResult*

An integer point that returns, by reference, the result of the verification. 0 means the message was verified; non-zero means it wasn't. The meaning of a non-zero return is defined by the algorithm provider.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function performs a block verification operation. For stream verification, use [CPMLibVerifyInit\(\)](#).

Keep in mind that a direct return of `errNone` doesn't mean that the message has been verified. The verification status is returned by reference in *verifyResult*.

## CPMLibVerifyFinal Function

<b>Purpose</b>	Finalizes a verify session.
<b>Declared In</b>	CPMLib.h
<b>Prototype</b>	<pre>Err CPMLibVerifyFinal ( UInt16 libRef,     APKeyInfoType *keyInfo,     APVerifyInfoType *verifyInfo, UInt8 *inBuffer,     UInt32 inBufferLength, UInt8 *outBuffer,     UInt32 *outBufferLength, UInt8 *signature,     UInt32 signatureLength,     VerifyResultType *verifyResult )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> CPM Library reference number (68k only).</p> <p>→ <i>verifyInfo</i> A pointer to the <a href="#">APVerifyInfoStruct</a> that was returned by <a href="#">CPMLibVerifyInit()</a>.</p> <p>→ <i>inBuffer</i> A pointer to the final buffer of message data, or NULL if there's no more data..</p> <p>→ <i>inBufferLength</i> The length of <i>inBuffer</i>, in bytes.</p> <p>← <i>outBuffer</i> A pointer to the buffer where the decrypted signature will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data. If you don't care about the signature, pass NULL.</p> <p>↔ <i>outBufferLength</i> If <i>outBuffer</i> is NULL, set this to 0. Otherwise, you pass in the (allocated) length of <i>outBuffer</i>, in bytes. The function resets the argument to the amount of data that was actually copied into <i>outBuffer</i>. If the function returns <code>cpmErrBufTooSmall</code>, <i>outBufferLength</i> is set to the minimum buffer size that's needed to accommodate the verified data.</p> <p>→ <i>signature</i> A pointer to the message's signature. Extracting the signature from the message is the caller's responsibility</p>

→ *signatureLength*

The length of the signature, in bytes.

← *verifyResult*

An integer point that returns, by reference, the result of the verification. 0 means the message was verified; non-zero means it wasn't. The meaning of a non-zero return is defined by the algorithm provider.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds a final (optional) buffer of message into a verify stream that was previously initialized by [CPMLibVerifyInit\(\)](#) and augmented through successive calls to [CPMLibVerifyUpdate\(\)](#). The entire message is then verified, the results of the verification are returned in `verifyResult`, and the stream is closed.

## CPMLibVerifyInit Function

**Purpose** Initiates a streaming verify operation.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibVerify ( UInt16 libRef,
                  APKeyInfoType *keyInfo,
                  APVerifyInfoType *verifyInfo )
```

**Parameters** → *libRef*  
 CPM Library reference number (68k only).

→ *keyInfo*

An [APKeyInfoStruct](#) that represents the certificate's encryption key. Extracting the key data from the certificate and constructing the [APKeyInfoStruct](#) (through [CPMLibImportKeyInfo\(\)](#)) is the caller's responsibility.

→ *verifyInfo*

A pointer to an [APVerifyInfoStruct](#) that specifies the hash and cipher operations that should be performed during verification. This information is embedded as [APHashInfoStruct](#) and [APCipherInfoStruct](#) structures. If you want to use the default operations, allocate and zero the embedded structures. When the function

returns, the structures will be populated with information describing the operations that were used.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function initializes a streaming hash operation. To feed data to the stream, you call [CPMLibVerifyUpdate\(\)](#) followed by [CPMLibVerifyFinal\(\)](#). The “update” function is optional; the “final” function is mandatory. For a block hash, see [CPMLibVerify\(\)](#).

## CPMLibVerifyUpdate Function

**Purpose** Sends message data to a streaming verify operation.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibVerifyUpdate ( UInt16 libRef,  
    APKeyInfoType *keyInfo,  
    APVerifyInfoType *verifyInfo )  
    UInt8 *inBuffer, UInt32 inBufferLength)
```

**Parameters**

- *libRef*  
CPM Library reference number (68k only).
- *keyInfo*  
The [APKeyInfoStruct](#) that was used in the [CPMLibVerifyInit\(\)](#) call.
- *verifyInfo*  
A pointer to the [APVerifyInfoStruct](#) that was returned by [CPMLibVerifyInit\(\)](#).
- *inBuffer*  
A pointer to the message data.
- *inBufferLength*  
The length of *inBuffer*, in bytes.

**Returns** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds message data into the verify stream that was initialized by [CPMLibVerifyInit\(\)](#). When you’re finished feeding data into the stream, call [CPMLibVerifyFinal\(\)](#) to close the stream and return the verification results.

## CPM Error Codes

The table below lists and explains the error codes that are returned by the CPM functions.

<code>cpmErrAlreadyOpen</code>	Returned by <code>CPMLibOpen()</code> to indicate that the CPM library has already been opened by your application. The open library remains open.
<code>cpmErrNotOpen</code>	All CPM functions (except <code>CPMLibOpen()</code> ) expect the CPM library to be open. This code is returned if the library isn't open. To open the library, call <code>CPMLibOpen()</code> .
<code>cpmErrStillOpen</code>	Returned by <code>CPMLibClose()</code> if the function was unable to close the library.
<code>cpmErrNoProviders</code>	Returned by <code>CPMLibOpen()</code> if the function was unable to locate (or load) any cryptography providers. Without a cryptography provider, none of the other CPM functions will work.
<code>cpmErrNoBaseProvider</code>	Returned by <code>CPMLibOpen()</code> if the function was unable to locate (or load) the default cryptography provider. (Note that this means that at least one non-default provider was found. If no providers were found, the function would have returned <code>cpmErrNoProviders</code> ).
<code>cpmErrProviderNotFound</code>	Returned by <code>CPMLibGenerateKey()</code> , <code>CPMLibEncrypt()</code> , <code>CPMLibDecrypt()</code> and other algorithm-dependent functions if the requested provider couldn't be found.
<code>cpmErrParamErr</code>	Returned by a number of CPM functions when an argument is invalid (a pointer that points to an unallocated structure; a structure field that isn't properly set, and so on).
<code>cpmErrOutOfMemory</code>	Returned by <code>CPMLibOpen()</code> if the memory for a new library handle (and the structures it represents) couldn't be allocated

---

<code>cpmErrBufTooSmall</code>	Returned by <code>CPMLibExportKey()</code> and <code>CPMLibExportContext()</code> functions if the storage buffer (allocated by the caller) isn't big enough to accommodate the key or context.
<code>cpmErrBadData</code>	Returned by algorithm functions ( <code>CPMLibEncrypt...()</code> , <code>CPMLibDecrypt...()</code> , etc.) when the key or other required data is invalid.
<code>cpmErrUnimplemented</code>	Returned by functions that aren't currently implemented.
<code>cpmErrUnsupported</code>	Returned by functions that aren't currently supported.
<code>cpmErrNoGlobals</code>	Returned by functions that access global CPM data—functions such as <code>CPMLibEnumerateProviders()</code> and <code>CPMLibGetProviderInfo()</code> —when that data doesn't exist.
<code>cpmErrKeyExists</code>	Returned by <code>CPMLibImportKey()</code> when the key you're trying to import already exists.
<code>cpmErrKeyNotFound</code>	Returned by <code>CPMLibExportKey()</code> when the key you're trying to export doesn't exist.

---

### *CPM Error Codes*

---

# SSL Functions

---

This chapter describes the functions that are defined in the SSL library. These functions let you create and configure an SSL context, apply the SSL protocol to an existing socket, and send SSL data to and receive data over the socket.

But before you do any of that, you have to load and open the SSL library; something like this:

---

```
Err error;
UInt16 libRef;

if ( SyLibFind( kSslDBName, &libRef ) != 0 )
{
    error = SysLibLoad(kSslLibType, kSslLibCreator, &libRef);
}
/* error checking goes here. */

error = SslLibOpen( libRef );
...
```

---

After that, you typically...

1. ...create an [SslLib](#) through [SslLibCreate\(\)](#),
2. spawn an [SslContext](#) through [SslContextCreate\(\)](#),
3. set the context's socket (see the [SslContextSet\\_Socket](#) macro),
4. "open" the context through [SslOpen\(\)](#) (this enables the SSL protocol),
5. send and receive data through [SslRead\(\)](#) and [SslWrite\(\)](#),
6. and then close everything down ([SslClose\(\)](#), [SslContextDestroy\(\)](#), [SslLibDestroy\(\)](#), and [SslLibClose\(\)](#), in that order).

You can also use the more detailed [SslSend\(\)](#) and [SslReceive\(\)](#) functions to send and receive data. If you want to

## SSL Functions

### *SSL Attribute Functions and Macros*

---

perform “streaming” reads—in which partial SSL records are read as the data arrives—use [SslPeek\(\)](#) and [SslConsume\(\)](#). (For more on streaming, see the [ReadStream](#) attribute).

All functions described below are defined in `SslLib.h`.

## SSL Attribute Functions and Macros

An SSL context is defined, primarily, by the values of its SSL attributes. These attributes are set and retrieved through attribute-specific macros. For example, the [SslLibSet\\_InfoCallback](#) macro sets an [SslLib](#)’s [InfoCallback](#) attribute.

The attribute macros are defined in terms of a set of eight functions listed in this chapter. These functions—[SslLibSetLong\(\)](#), [SslContextSetLong\(\)](#), [SslLibSetPtr\(\)](#), [SslContextSetPtr\(\)](#), and so on—*can* be called directly, but it’s suggested that you stick with the macros. If you want to call an attribute function directly, you have to identify the attribute by passing in one of the attribute constants.

The attribute macros and constants are described in [Chapter 82](#), “[SSL Attributes and Macros](#),” on page 2087.

## A Note on the Function Names

All of the SSL library functions have “Ssl” as a prefix. Furthermore, the expected Palm library functions ([SslLibOpen\(\)](#), [SslLibClose\(\)](#)) have an equally expected “SslLib” prefix. Unfortunately, another set of functions also uses “SslLib” as a prefix. These functions, [SslLibCreate\(\)](#), [SslLibDestroy\(\)](#), and so on, operate on instances of the [SslLib](#) data type, which type represents a generic SSL context.

Admittedly, “SslLib” is bad choice for the name of this data type. As pointed out in [Chapter 81](#), “[SSL Structures and Data Types](#),” when you see the [SslLib](#) data type, you should think “generic SSL context,” not “SSL library.”

## SSL Library Functions

### SslClose Function

<b>Purpose</b>	Shuts down an SSL session.
<b>Prototype</b>	<code>Err SslClose ( UInt16 libRef, SslContext *context, UInt16 flags, UInt32 timeout )</code>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) SSL library reference number.</p> <p>→ <i>context</i> The context that you want to close.</p> <p>→ <i>flags</i> Options that set the session's "shutdown" attributes.</p> <p>→ <i>timeout</i> Amount of time to wait for the final handshake messages from the server, in milliseconds.</p>
<b>Returns</b>	<code>errNone</code> means success; for other codes, see <a href="#">Chapter 83</a> , "SSL Error Codes."
<b>Comments</b>	<p>By default, an SSL shutdown involves an exchange of messages with the server. As with <a href="#">SslOpen()</a>, if this function times out, simply call it repeatedly until you get confirmation that the session has actually been closed (i.e. until the function returns <code>errNone</code>). Unlike with <a href="#">SslClose()</a>, you needn't clear the flags when you recall this function.</p> <p>The flags set the SSL attributes that are used during the shutdown:</p>

## SSL Functions

### *SslConsume*

---

Flag	Meaning
<code>sslCloseUseDefaultTimeout</code>	If this flag is set, the current value of the <a href="#">IoTimeout</a> attribute is used as the function's timeout, overriding the timeout argument. If it isn't set, <a href="#">IoTimeout</a> is set to timeout and is used as the timeout for this function.
<code>sslCloseDontSendShutdown</code>	Sets the <a href="#">DontSendShutdown</a> attribute to 1. This suppresses the shutdown messages.
<code>sslCloseDontWaitForShutdown</code>	Sets the <a href="#">DontWaitForShutdown</a> attribute to 1. This tells the function to return after it sends a shutdown message to the server, thus ignoring the server's response.

---

## SslConsume Function

<b>Purpose</b>	Removes data from a context's in-coming data buffer. Use after an <a href="#">SslPeek()</a> only.
<b>Prototype</b>	<pre>void SslConsume ( UInt16 libRef,                   SslContext *context, Int32 availableBytes )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) SSL library reference number.</p> <p>→ <i>context</i> Context you want to look at.</p> <p>→ <i>availableBytes</i> The number of bytes to remove. This should always be the value that's returned to you by <a href="#">SslPeek()</a>'s <code>availableBytes</code> argument.</p>
<b>Comments</b>	You call this function after calling <a href="#">SslPeek()</a> to remove the peeked at data.

## SslContextCreate Function

<b>Purpose</b>	Creates a new SSL context. The object is used to open, read, write, and close an SSL session.
<b>Prototype</b>	<pre>Err SslContextCreate ( UInt16 libRef,                       SslLib *contextTemplate,                       SslContext **context )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) SSL library reference number.</p> <p>→ <i>contextTemplate</i> Pointer to an <a href="#">SslLib</a> object that will be used as the template for this context.</p> <p>← <i>context</i> You pass in the address of an <a href="#">SslContext</a> pointer. The function allocates a new <a href="#">SslContext</a> object and points your pointer at it.</p>
<b>Returns</b>	<code>errNone</code> means success; for other codes, see <a href="#">Chapter 83, “SSL Error Codes.”</a>
<b>Comments</b>	<p>The attributes that have been set in <code>contextTemplate</code> are copied into <code>context</code>. These attributes don’t include a network socket; setting the socket is typically the first thing you do with your context object. For instructions, see <a href="#">Socket</a> in <a href="#">Chapter 82, “SSL Attributes and Macros,”</a> on page 2087.</p> <p>After you set its socket, the context object can be used to open an SSL session; see <a href="#">SslOpen()</a>.</p> <p>When you’re finished using your context object, you close the session (<a href="#">SslClose()</a>) and the destroy the object by passing it to <a href="#">SslContextDestroy()</a>.</p>

## SslContextDestroy Function

- Purpose** Destroys an SSL context. You should close the object's SSL session (see [SslClose\(\)](#)) before destroying it.
- Prototype** `Err SslContextDestroy ( UInt16 libRef,  
SslContext *context)`
- Parameters**   
→ *libRef*  
(68k only) SSL library reference number.  
→ *context*  
The context you wish to demolish.
- Returns** `errNone` means success; for other codes, see [Chapter 83, "SSL Error Codes."](#)
- See Also** [SslContextCreate\(\)](#)

## SslContextGetLong Function

- Purpose** Returns the value of an integer-valued SSL attribute retrieved from a context.
- Prototype** `Int32 SslLibGetLong ( UInt16 libRef,  
SslContext *context, SslAttribute attribute )`
- Parameters**   
→ *libRef*  
(68k only) SSL library reference number.  
→ *context*  
The context that contains the attribute.  
→ *attribute*  
Constant that represents the attribute that you want the value of. See "[SSL Attribute Constants](#)" in [Chapter 82, "SSL Attributes and Macros,"](#) on page 2087 for a list of attribute constants.
- Returns** The attribute's value is returned directly.

- Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.
- See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslContextSetLong\(\)](#), [SslContextSetPtr\(\)](#), [SslContextGetPtr\(\)](#)

## SslContextGetPtr Function

- Purpose** Returns a pointer to an attribute that’s owned by a context template.
- Prototype**

```
Err SslLibGetPtr ( UInt16 libRef,  
                  SslContext *context, SslAttribute attribute,  
                  void **value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *context*  
The context that contains the attribute.
  - *attribute*  
Constant that represents the attribute that you want the value of. “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087 for a list of attribute constants.
  - *value*  
You pass in the address of a pointer; the function will point your pointer to the attribute’s data. The data’s type depends on the attribute. You mustn’t free or modify the pointed to data.
- Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

## SslContextSetLong Function

- Purpose** Modifies a context by changing the value of one of its integer-valued SSL attributes.
- Prototype**

```
Err SslLibSetLong ( UInt16 libRef,  
                  SslContext *context, SslAttribute attribute,  
                  Int32 value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *context*  
The context template you want to modify.
  - *attribute*  
Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087 for a list of attribute constants.
  - *value*  
The attribute’s new (desired) value.
- Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)
- Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.
- See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslContextSetPtr\(\)](#), [SslContextGetLong\(\)](#), [SslContextGetPtr\(\)](#)

## SslContextSetPtr Function

- Purpose** Modifies a context template by changing the value of one of its pointer-valued SSL attributes.
- Prototype**

```
Err SslLibSetPtr ( UInt16 libRef,  
                  SslContext *context, SslAttribute attribute,  
                  void *value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.

→ *context*

The context you want to modify.

→ *attribute*

Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82](#), “[SSL Attributes and Macros](#),” on page 2087 for a list of attribute constants.

→ *value*

A pointer to the attribute’s new (desired) value. The type of data that the pointer should point to is defined by the attribute.

**Returns** `errNone` means success; for other codes, see [Chapter 83](#), “[SSL Error Codes](#).”

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82](#), “[SSL Attributes and Macros](#),” on page 2087, [SslContextSetLong\(\)](#), [SslContextGetLong\(\)](#), [SslContextGetPtr\(\)](#)

## SslFlush Function

**Purpose** Flushes a context’s out-going data buffer, sending the data to the network.

**Prototype** `Err SslFlush ( Int16 libRef, SslContext *context, Int32 *outstanding )`

**Parameters** → *libRef*  
(68k only) SSL library reference number.

→ *context*  
Context you want to flush.

← *outstanding*  
The number of bytes of data left in the buffer.

**Returns** `errNone` means success; for other codes, see [Chapter 83](#), “[SSL Error Codes](#).”

**Comments** If the context is in autoflush mode (the [AutoFlush](#) attribute is 0), [SslWrite\(\)](#) and [SslSend\(\)](#) calls will write their data into the

## SSL Functions

### *SslLibClose*

---

context's out-going data buffer, but the data won't actually be sent to the network. To "flush" this data, you have to explicitly call `SslFlush`.

By not autoflushing, you can make multiple, small [SslWrite\(\)](#)/[SslSend\(\)](#) followed by an `SslFlush` and thereby improve network efficiency. Although the out-going buffer size is set to the value of the [WbufSize](#) attribute, the actual number of bytes that can be written by your application is somewhat smaller due to SSL overhead. After performing a write, you should check the value of the [WriteBufPending](#) attribute; if it's approaching the [WbufSize](#) value, you should call `SslFlush`.

When the function returns, the outstanding value tells how many bytes of data are left in the buffer. If this value is non-zero, the next [SslWrite\(\)](#), [SslSend\(\)](#), or `SslFlush` call will attempt to write those bytes to the network.

### SslLibClose Function

<b>Purpose</b>	Closes a reference to the SSL library.
<b>Prototype</b>	<code>Err SslLibClose ( UInt16 refNum )</code>
<b>Parameters</b>	<code>→ refNum</code> SSL library reference number (68k only).
<b>Returns</b>	<code>errNone</code> means success; for other codes, see <a href="#">Chapter 83</a> , " <a href="#">SSL Error Codes</a> ."
<b>Comments</b>	You can only a library that you've already opened. To open the SSL library, call <a href="#">SslLibOpen()</a> .

## SslLibCreate Function

<b>Purpose</b>	Allocates and returns new <a href="#">SslLib</a> object. The object is a template that describes a generic SSL context, and is used to create “real” context objects ( <a href="#">SslContext</a> ).
<b>Declared In</b>	<code>SslLib.h</code>
<b>Prototype</b>	<pre>Err SslLibCreate ( UInt16 libRef,                   SslLib **contextTemplate )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) SSL library reference number.</p> <p>← <i>contextTemplate</i> You pass in the address of an <a href="#">SslLib</a> pointer. The function allocates an <a href="#">SslLib</a> object for you, and points your pointer at it.</p>
<b>Returns</b>	<code>errNone</code> means success; for other codes, see <a href="#">Chapter 83</a> , “ <a href="#">SSL Error Codes</a> .”
<b>Comments</b>	<p>You modify the context template (i.e the <a href="#">SslLib</a> object) by calling the SSL attribute macros described in <a href="#">Chapter 82</a>, “<a href="#">SSL Attributes and Macros</a>.” You then use it as a template with which you create <a href="#">SslContext</a> objects (see <a href="#">SslContextCreate()</a>). The latter objects are needed for actual SSL data transaction operations.</p> <p>The <i>contextTemplate</i> that’s returned by this function should ultimately be destroyed through <a href="#">SslLibDestroy()</a>.</p> <p>For more on <code>SslLib</code>, <code>SslContext</code>, and the relationship between them, see their descriptions in <a href="#">Chapter 81</a>, “<a href="#">SSL Structures and Data Types</a>,” on page 2069.</p>

## SslLibDestroy Function

<b>Purpose</b>	Destroys an <a href="#">SslLib</a> object and frees all the memory it allocated.
<b>Prototype</b>	<pre>void SslLibDestroy ( UInt16 libRef,                     SslLib *contextTemplate )</pre>
<b>Parameters</b>	<p>→ <i>libRef</i> (68k only) SSL library reference number.</p>

## SSL Functions

### *SslLibOpen*

---

→ *contextTemplate*

The [SslLib](#) you want to destroy, as previously returned by [SslLibCreate\(\)](#).

**Returns** `errNone` means success; for other codes, see [Chapter 83](#), “[SSL Error Codes](#).”

**Comments** The [SslContext](#) objects that were spawned by this [SslLib](#) maintain a reference to their spawner. Because of this, you shouldn’t destroy an [SslLib](#) until you’ve destroyed all of its contexts.

## SslLibOpen Function

**Purpose** Opens a reference to the SSL library.

**Prototype** `Err SslLibOpen ( UInt16 libRef )`

**Parameters** → *libRef*  
(68k only) SSL library reference number.

**Returns** `errNone` means success; for other codes, see [Chapter 83](#), “[SSL Error Codes](#).”

**Comments** When you’re done using the SSL library, you must close it through [SslLibClose\(\)](#)

## SslLibGetLong Function

**Purpose** Returns the value of an integer-valued SSL attribute retrieved from a context template.

**Prototype** `Int32 SslLibGetLong ( UInt16 libRef,  
SslLib *contextTemplate,  
SslAttribute attribute )`

**Parameters** → *libRef*  
(68k only) SSL library reference number.

→ *contextTemplate*

The context template that contains the attribute.

→ *attribute*

Constant that represents the attribute that you want the value of. See “[SSL Attribute Constants](#)” in [Chapter 82](#), “[SSL](#)

[Attributes and Macros](#),” on page 2087 for a list of attribute constants.

- Returns** The attribute’s value is returned directly.
- Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.
- See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslLibSetLong\(\)](#), [SslLibSetPtr\(\)](#), [SslLibGetPtr\(\)](#)

## SslLibGetPtr Function

- Purpose** Returns a pointer to an attribute that’s owned by a context template.
- Prototype**
- ```
Err SslLibGetPtr ( UInt16 libRef,  
                  SslLib *contextTemplate,  
                  SslAttribute attribute,  
                  void **value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *contextTemplate*  
The context template that contains the attribute.
  - *attribute*  
Constant that represents the attribute that you want the value of. “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087 for a list of attribute constants.
  - *value*  
You pass in the address of a pointer; the function will point your pointer to the attribute’s data. The data’s type depends on the attribute. You mustn’t free or modify the pointed to data.
- Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)
- Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.
- See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslLibSetLong\(\)](#), [SslLibGetLong\(\)](#), [SslLibSetPtr\(\)](#)

## SslLibSetLong Function

- Purpose** Modifies a context template by changing the value of one of its integer-valued SSL attributes.
- Prototype**

```
Err SslLibSetLong ( UInt16 libRef,  
                  SslLib *contextTemplate,  
                  SslAttribute attribute,  
                  Int32 value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *contextTemplate*  
The context template you want to modify.
  - *attribute*  
Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087 for a list of attribute constants.
  - *value*  
The attribute’s new (desired) value.
- Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)
- Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.
- See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslLibSetPtr\(\)](#), [SslLibGetLong\(\)](#), [SslLibGetPtr\(\)](#)

## SslLibSetPtr Function

- Purpose** Modifies a context template by changing the value of one of its pointer-valued SSL attributes.
- Prototype**

```
Err SslLibSetPtr ( UInt16 libRef,  
                  SslLib *contextTemplate,  
                  SslAttribute attribute,  
                  void *value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.

→ *contextTemplate*

The context template you want to modify.

→ *attribute*

Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros](#),” on page 2087 for a list of attribute constants.

→ *value*

A pointer to the attribute’s new (desired) value. The type of data that the pointer should point to is defined by the attribute.

**Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslLibSetLong\(\)](#), [SslLibGetLong\(\)](#), [SslLibGetPtr\(\)](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087, [SslContextGetLong\(\)](#), [SslContextSetLong\(\)](#), [SslContextSetPtr\(\)](#)

## SslOpen Function

**Purpose** Opens an SSL session, possibly as a continuation of a previous session.

**Prototype** `Err SslOpen ( UInt16 libRef, SslContext *context, UInt16 flags, UInt32 timeout )`

**Parameters** → *libRef*  
(68k only) SSL library reference number.

→ *context*  
The context object that will configure and own the session.

## SSL Functions

### *SslOpen*

---

→ *flags*

Options that set various SSL attributes. The most important flags are `sslOpenModeSsl` and `sslOpenModeClear`. These mutually exclusive flags tell the session to use SSL or cleartext, respectively.

→ *timeout*

Amount of time to wait for the handshake confirmation before giving up, in milliseconds.

**Returns** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** Calling `SslOpen` is essentially the same as setting the attributes that correspond to the function’s flags:

| Flag                              | Meaning                                                                                                                                                                                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslOpenModeClear</code>     | Sets the context’s <a href="#">Mode</a> attribute to <code>sslModeClear</code> (cleartext).                                                                                                                                                       |
| <code>sslOpenModeSsl</code>       | Sets the context’s <a href="#">Mode</a> attribute to <code>sslModeSslClient</code> (SSL is enabled). This overrides <code>sslOpenModeClear</code> .                                                                                               |
| <code>sslOpenNoAutoFlush</code>   | Sets the <a href="#">AutoFlush</a> attribute to 0. This suppresses auto-flushing so that <a href="#">SslWrite()</a> / <a href="#">SslSend()</a> data is cached until you call <a href="#">SslFlush()</a> .                                        |
| <code>sslOpenNewConnection</code> | Sets the context’s <a href="#">SslSession</a> attribute to <code>NULL</code> . This will force a full SSL handshake. If you don’t set this flag, the previous <code>SslSession</code> will be used (if possible), and the handshake is truncated. |
| <code>sslOpenBufferedReuse</code> | Sets the <a href="#">BufferedReuse</a> attribute to 1. This provides an even greater savings during a (truncated) handshake.                                                                                                                      |

| Flag                                  | Meaning                                                                                                                                                                                                                                                          |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslOpenUseDefaultTimeout</code> | If this flag is set, the current value of the <a href="#">IoTimeout</a> attribute is used as the function's timeout, overriding the timeout argument. If it isn't set, <a href="#">IoTimeout</a> is set to timeout and is used as the timeout for this function. |
| <code>sslOpenDelayHandshake</code>    | Instead of sending the final handshake message, cache it until the write buffer is flushed (through an autoflush, or through an <a href="#">SslFlush()</a> call). There is no attribute that corresponds to this flag.                                           |

If the function times out, you should simply call it again—timing out isn't a fatal error. Each time you call `SslOpen` (after a timeout), the handshake continues from where it timed out. However, it's important that when you re-call `SslOpen`, that you clear the flags argument. The attributes that they affect will already have been set; setting them a second time could cause the context to be reset, which will cause the handshake to start from the beginning.

## SslPeek Function

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Lets you look at in-coming data without actually “consuming” it.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>  | <pre>Err SslPeek ( UInt16 libRef, SslContext *context,               void **data, Int32 *availableBytes,               Int32 maxAvailable)</pre>                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b> | <p>→ <i>libRef</i><br/>(68k only) SSL library reference number.</p> <p>→ <i>context</i><br/>Context you want to look at.</p> <p>← <i>data</i><br/>Pass in the address of a pointer; the function sets your pointer to point to the context's in-coming data buffer.</p> <p>← <i>availableBytes</i><br/>The function returns the smaller of <b>a</b>) the number of bytes of data that are waiting to be read or <b>b</b>) the value of <code>maxAvailable</code>.</p> |

## SSL Functions

### *SslRead*

---

→ *maxAvailable*

Sets a limit on the `availableBytes` value.

**Returns** Always returns 0.

**Comments** This function is similar to [SslRead\(\)](#), but rather than copy data into your buffer, it gives you direct access to the context's in-coming data buffer. If the buffer is empty, data is read from the network until there are bytes available. After each successful `SslPeek` call, you should call [SslConsume\(\)](#) to clear the "peeked at" data. If you don't consume after a peek, the next `SslPeek` will return a pointer to the same data.

`SslPeek` is meant to be used in contexts that have the [ReadStreaming](#) attribute set.

## SslRead Function

**Purpose** Copies a buffer of in-coming data.

**Prototype**

```
Int16 SslRead ( UInt16 libRef,  
                SslContext *context, void *buffer,  
                UInt16 bufferLength, Err *error )
```

**Parameters** → *libRef*  
(68k only) SSL library reference number.

→ *context*  
Context that owns the session.

← *buffer*  
This is where the retrieved data will be copied. The buffer must be allocated by the caller.

→ *bufferLength*  
The length of *buffer*, in bytes.

← *error*  
Error code as listed in see [Chapter 83](#), "[SSL Error Codes](#)."

**Returns** Returns the number of bytes that were actually read. A return of 0 means the socket was shut down by the server. If the return is -1, look in *error* for the precise error code.

**Comments** This is a convenient cover for [SslReceive\(\)](#). It ignores the address of the sender, doesn't set any socket flags, and uses the context's current timeout setting (the [IoTimeout](#) attribute).

## SslReceive Function

**Purpose** Copies a buffer of in-coming data.

**Prototype**

```
Int16 SslReceive ( UInt16 libRef,
                  SslContext *context, void *buffer,
                  UInt16 bufferLength, UInt16 flags,
                  void *fromAddress, UInt16 *fromAddressLength,
                  Int32 timeout, Err *error )
```

**Parameters**

- *libRef*  
(68k only) SSL library reference number.
- *context*  
Context that owns the session.
- ← *buffer*  
This is where the retrieved data will be placed.
- *bufferLength*  
The length of *buffer*, in bytes.
- *flags*  
Options that are applied to (and stored by) the socket. See [I/O Flags](#) in [Chapter 61, "Net Library,"](#) on page 1349 for a description of these options.
- ← *fromAddress*  
Optionally returns the address of the sender. The *fromAddress* buffer must be allocated by the caller. If you don't want to retrieve the address, pass a NULL pointer.
- ↔ *fromAddressLength*  
On input, you set *\*fromAddressLength* to the size of the *fromAddress* buffer, in bytes. Upon return, *\*fromAddressLength* is set to the actual size of the buffer. If you don't want to retrieve the address, pass a NULL pointer.
- *timeout*  
Maximum timeout in system ticks; -1 means wait forever.

## SSL Functions

### *SslSend*

---

← *error*

Error code as listed in see [Chapter 83](#), “[SSL Error Codes](#).”

**Returns** Returns the number of bytes that were actually read. A return of 0 means the socket was shut down by the server. If the return is -1, look in *error* for the precise error code.

**Comments** Unlike in `SslSend`, the address that you supply (`fromAddress`) doesn't overwrite the socket's address. This is a cover for the Network library's [NetLibDmReceive\(\)](#) function.

For a shorthand version of this function, see [SslRead\(\)](#).

## SslSend Function

**Purpose** Writes a buffer of data to the network, or buffers it for a later send.

**Prototype** `Int16 SslSend ( UInt16 libRef,  
                  SslContext *context, void *buffer,  
                  UInt16 bufferLength, UInt16 flags,  
                  void *toAddress, UInt16 toAddressLength,  
                  Int32 timeout, Err *error )`

**Parameters**

- *libRef*  
(68k only) SSL library reference number.
- *context*  
Context that owns the SSL session.
- *buffer*  
A pointer to the data that you want to write.
- *bufferLength*  
The amount of data you want to write, in bytes.
- *flags*  
Options that are applied to (and stored by) the socket. See [I/O Flags](#) in [Chapter 61](#), “[Net Library](#),” on page 1349 for a description of these options.
- *toAddress*  
Address of the recipient. If this is a [NetSocketAddrType](#), the socket's address is set to this value. If it's 0, the socket's current address is used.
- *toAddressLength*  
Size of *\*toAddress*, in bytes.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *error*

Error code as listed in see [Chapter 83, “SSL Error Codes.”](#)

**Returns** Returns the number of bytes that were actually sent. A return of 0 means the socket was shut down by the server. If the return is -1, look in *error* for the precise error code.

**Comments** If the context has the [AutoFlush](#) attribute enabled, the data is immediately written to the network; otherwise, it’s cached until [SslFlush\(\)](#) is called. This function is a cover for the Network library’s [NetLibSend\(\)](#) function.

For a shorthand version of this function, see [SslWrite\(\)](#).

## SslWrite Function

**Purpose** Writes a buffer of data to the network, or caches it in anticipation of a flush.

**Prototype**

```
Int16 SslWrite ( UInt16 libRef,
                SslContext *context, void *buffer,
                UInt16 bufferLength, Err *error )
```

**Parameters**

- *libRef*  
(68k only) SSL library reference number.
- *context*  
Context that owns the session.
- *buffer*  
A pointer to the data that you want to write.
- *bufferLength*  
The amount of data you want to write, in bytes.
- ← *error*  
Error code as listed in see [Chapter 83, “SSL Error Codes.”](#)

**Returns** Returns the number of bytes that were actually sent. A return of 0 means the socket was shut down by the server. If the return is -1, look in *error* for the precise error code.

## SSL Functions

### Application-Defined Functions

---

**Comments** This is a convenient cover for [SslSend\(\)](#). It doesn't set any socket flags, uses the socket's current address, and uses the context's current timeout setting (the [IoTimeout](#) attribute).

## Application-Defined Functions

### SslCallbackFunc Function

**Purpose** Prototype for SSL information and verification callback functions.

**Prototype**

```
typedef Int32
    (*SslCallbackFunc) (SslCallback *callbackStruct
        ,
        Int32 command, Int32 flavor, void *info);
```

**Parameters** → *callbackStruct*  
A structure that contains information about this callback function, including application-defined data that can be used in the function's implementation. See [SslCallback](#) in [Chapter 81, "SSL Structures and Data Types,"](#) on page 2069.

→ *command*  
A constant that represents the general reason for the function's invocation.

→ *flavor*  
A constant that refines the *command* value.

→ *info*  
Additional data that may be needed by the callback. The type of data that's passed depends on the *command*/*flavor* values.

**Returns** The function should return `errNone` (0) upon success, otherwise, it should return one of the error codes described in [Chapter 83, "SSL Error Codes."](#) A non-zero return value here is returned to the SSL function that caused the callback to be invoked.

**Comments** For every context, you can install two callback functions: An "info" callback and a "verify" callback:

- The info callback is typically used for debugging, displaying data, tracking progress, and so on. It's invoked at well-defined junctures as the context is working.

- The verify callback is called when a certificate is being verified. It's expected to handle error situations.

To install a callback, you create an [SslCallback](#) structure, populate the necessary fields, and then use it to set the value of the [InfoCallback](#) or [VerifyCallback](#) attribute. When you set the info callback, you also have to set the [InfoInterest](#) attribute to register for specific events (which will show up in the `flavor` argument when your callback is invoked). The verify callback doesn't require similar event registration.

Setting the info callback in an [SslContext](#) looks a little bit like this:

---

```
/* Create an SslCallback structure, and point its
 * 'callback' field to your function ('MyInfoCallbackFunc').
 */
SslCallback infoCallback;
infoCallback.callback = MyInfoCallbackFunc;

/* Set the InfoCallback attribute. */
SslContextSet_InfoCallback( sslContext, &infoCallback );

/* Set the events you're interested in hearing about. */
SslContextSet_InfoInterest( sslContext,
    sslFlgInfoAlert | sslFlgInfoHandshake | sslFlgInfoIo );
```

---

When you set the [InfoCallback](#) or [VerifyCallback](#) attribute, the [SslCallback](#) structure is copied into the object. Furthermore, when you spawn an [SslContext](#) from an [SslLib](#), the callback structures are copied into the new object.

### **Commands and Flavors**

Taken together, the command and flavor arguments tell a callback why it's being called. There are three command groups:

- The common command values (`sslCmdNew`, `sslResetNew`, and `sslCmdFree`) apply to both info and verify callbacks. These commands don't use flavor arguments.
- `sslCmdInfo` is used for info callbacks only. The `flavor` argument indicates the reason for the callback.
- Similarly, `sslCmdVerify` is used for verify callbacks only (and `flavor` refines the command's meaning).

## SSL Functions

### *SslCallbackFunc*

---

#### **Common Commands**

The common commands are:

| Command                  | Meaning                                                                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslCmdNew</code>   | The callback function was just copied into an object. (More accurately, the <a href="#">SslCallback</a> that contains the function was copied.) This happens when you set the <a href="#">InfoCallback</a> or <a href="#">VerifyCallback</a> attribute, or when you spawn an <a href="#">SslContext</a> . |
| <code>sslCmdReset</code> | The context that contains this callback was just reset ( <a href="#">SslContext</a> only; see the <a href="#">Mode</a> attribute for a brief explanation of the SSL reset).                                                                                                                               |
| <code>sslCmdFree</code>  | The <a href="#">SslCallback</a> structure is about to be freed. This usually means that the <a href="#">SslLib</a> or <a href="#">SslContext</a> that owns the structure is being destroyed.                                                                                                              |

When a callback function is invoked with one of these common commands, the `flavor` argument is 0 (i.e. undefined) and `info` is `NULL`.

#### ***sslCmdInfo Flavors***

As mentioned above, the `sslCmdInfo` command argument is only sent to the info callback (keep in mind, however, that the info callback may also receive any of the common commands).

The `flavor` values that are associated with the `sslCmdInfo` command are:

| Flavor                                                                                       | Meaning                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sslArgInfoHandshake                                                                          | Notification of an SSL state change. Read the <a href="#">HsState</a> attribute to determine the new state.                                                                                                                                          |
| sslArgInfoAlert                                                                              | <p>The callback's info parameter is set to NULL.</p> <p>Notification of an SSL alert. Your callback can read the <a href="#">LastAlert</a> attribute to determine which alert was received.</p> <p>The callback's info parameter is set to NULL.</p> |
| sslArgInfoReadBefore<br>sslArgInfoReadAfter<br>sslArgInfoWriteBefore<br>sslArgInfoWriteAfter | <p>Notifications that are sent just before and just after data is read from or written to the network.</p> <p>The info argument is an <a href="#">SslIoBuf</a> structure that contains the data.</p>                                                 |
| sslArgCert                                                                                   | <p>Notification that the server's certificate chain has been verified.</p> <p>The info argument is an <a href="#">SslExtendedItems</a> structure that contains the server's certificate.</p>                                                         |

### ***sslCmdVerify Flavors***

The verify callback function is called with the `sslCmdVerify` command when an error occurs during certificate verification, and when the certificate is successfully verified. The associated flavor values are:

## SSL Functions

*SslCallbackFunc*

---

| Flavor                                            | Meaning                                                                                                     |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>sslErrVerifyBadSignature</code>             | The certificate's signature is invalid                                                                      |
| <code>sslErrVerifyNoTrustedRoot</code>            | A trusted certificate store (necessary for certificate verification) couldn't be found                      |
| <code>sslErrVerifyNotAfter</code>                 | The certificate has expired.                                                                                |
| <code>sslErrVerifyNotBefore</code>                | The certificate is too early (the timestamp window is in the future).                                       |
| <code>sslErrVerifyConstraintViolation</code>      | The certificate violates an X509 extension                                                                  |
| <code>sslErrVerifyUnknownCriticalExtension</code> | An X509 extension (that's marked as "critical") isn't understood by the certificate verification routines.y |
| <code>sslErrOk</code>                             | The certificate was successfully verified.                                                                  |

Note that these constants are also used as error codes. If your verify function can't fix the problem, it should return the command argument as an error.

In all cases, the `info` argument is an [SslVerify](#) structure that contains information about the certificate that's being verified.

# SSL Structures and Data Types

---

This chapter describes the structures and data types that are used by SSL.

All elements described below are defined in `SslLib.h`.

## SSL Data Types

### SslAttribute Typedef

**Purpose** The `SslAttribute` data type is used to cast the SSL attribute constants that are passed to the attribute-setting functions.

**Prototype** `typedef UInt32 SslAttribute;`

In general, you should use the attribute-setting macros rather than the functions. The attribute upon which a macro operates is embedded in its name, so you rarely have to deal with `SslAttribute` types.

For more information on the relationship between the attribute-setting functions and macros, see [Chapter 80, “SSL Functions,”](#) on page 2043. For a list of the macros themselves, go to [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087.

### SslContext Typedef

**Purpose** `SslContext` is the data type for a private structure that holds all the information, or *context*, associated with the SSL protocol that will be used in an SSL session. It contains flags that govern how the SSL protocol will operate, read and write buffers where SSL packets

## SSL Structures and Data Types

### *SslLib*

---

are assembled and disassembled, various structures that are created as part of the SSL handshake, and so on.

The data type is declared in `SslLib.h` as:

**Prototype** `typedef struct SslContext_st SslContext;`

The lifetime of an `SslContext` follows this pattern:

1. **Creation.** You never allocate your own `SslContext` objects; instead, you first create an [SslLib](#) (which see) and pass it to the [SslContextCreate\(\)](#) function. The [SslLib](#) acts as a template that's used by the function to create and configure a new `SslContext`. This "configuration" consists of copying the [SslLib](#)'s **SSL attributes** into the new `SslContext`.
2. **Configuration.** After you get your hands on the new `SslContext`, you can refine its SSL attributes by calling the SSL attribute macros.
3. **Socket specification.** The one essential attribute that you must set is the context's socket. The template doesn't contain a reference to a socket, so if you want to actually use the `SslContext` object's that you create, you have to explicitly set its socket. See [Socket](#) in [Chapter 82, "SSL Attributes and Macros."](#)
4. **SSL sessions.** You then pass the `SslContext` to [SslOpen\(\)](#), which creates a new SSL session. The `SslContext` is used as a cookie in session operations such as [SslRead\(\)](#) and [SslClose\(\)](#). When you're done with the session, you call [SslClose\(\)](#). The same `SslContext` can be reused in successive sessions, but only one at a time.
5. **Destruction.** When you're done using the SSL context, you hand the object back to the system through [SslContextDestroy\(\)](#).

## SslLib Typedef

**Purpose** `SslLib` is the data type for a private structure that describes a generic SSL context. It's declared in `SslLib.h` as:

---

**Prototype**    `typedef struct SslLib_st    SslLib;`

---

**NOTE:** `SslLib` is a misleading name for this data type. The type *doesn't* represent the SSL library, nor does it serve any explicit library-related function. Where you see “`SslLib`” you should think “generic SSL context.”

---

After you create and modify an `SslLib` object, you use it as a template to create “real” SSL context objects (type [SslContext](#)). When you're done with the `SslLib`, you ask the SSL library to destroy it.

Functionally, the lifetime of an `SslLib` follows this pattern:

1. **Creation.** You create the object through [SslLibCreate\(\)](#).
2. **Modification.** Since the structure that the `SslLib` represents is private, you can't touch its fields directly. Instead, you use a set of macros (defined in `SslLibMac.h`) to fine-tune the object. These macros set the values of the **SSL attributes** that the `SslLib` contains. The SSL attributes and the macros that you use to set and get their values are described in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2087.
3. **Context creation.** When you're satisfied with your `SslLib`'s attribute configuration, you use it to create new [SslContext](#) objects through the [SslContextCreate\(\)](#) function. The `SslLib`'s attributes are copied into the new [SslContext](#). Subsequent changes to the `SslLib` won't affect the [SslContext](#) objects that you've already created.
4. **Destruction.** When you're done with your `SslLib` and all of its [SslContexts](#) you should destroy it by passing it to [SslLibDestroy\(\)](#). Note that each [SslContext](#) object keeps a reference to the `SslLib` that calved it, so you mustn't destroy an `SslLib` until after its [SslContext](#) objects have been freed.

You can create as many `SslLib` objects as you want, but you typically only create one per application.

# SSL Structures

## SslCallback Struct

**Purpose** The SslCallback structure contains information about a callback function that’s invoked during SSL operations.

**Prototype**

```
typedef struct {
    void *reserved;
    SslLibCallbackFunc callback;
    void *data;
    SslContext *ssl;
} SslCallback
```

The fields are:

|          |                                                                                                                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| callback | A pointer to a callback function.                                                                                                                                                                           |
| data     | A pointer to data that’s passed to the callback function when it’s invoked.                                                                                                                                 |
| ssl      | The SSL context to which the callback applies, or NULL if it’s not specific to a context. You never set this field; it’s set for you when the callback is copied into an <a href="#">SslContext</a> object. |
| reserved | Reserved for future use.                                                                                                                                                                                    |

There are two types of callback functions: info and verify. The info callback is called as data is being read, when the server sends an alert, and so on. The verify callback is called when a certificate is being verified.

To register a callback function, you create an SslLibCallback structure, fill out the callback and data fields, and then use the structure to set the value of the [InfoCallback](#) or [VerifyCallback](#) attribute. To set the attribute you call one of these macros:

- [SslLibSet\\_InfoCallback](#) sets the [InfoCallback](#) attribute of an [SslLib](#) object.
- [SslLibSet\\_VerifyCallback](#) sets the [VerifyCallback](#) attribute of an [SslLib](#) object.
- [SslContextSet\\_InfoCallback](#) sets the [InfoCallback](#) attribute of an [SslContext](#) object.
- [SslContextSet\\_VerifyCallback](#) sets the [VerifyCallback](#) attribute of an [SslContext](#) object.

When you register an info callback you must also set the [InfoInterest](#) attribute by calling [SslLibSet\\_InfoInterest](#) or [SslContextSet\\_InfoInterest](#) macro. The [InfoInterest](#) attribute contains a list of the events that your info callback is interested in.

As with (nearly) all SSL attributes, the callbacks that you set in an [SslLib](#) are copied into the [SslContext](#) objects that it spawns.

You can use the same [SslLibCallback](#) structure to set more than one callback function. After you've called a callback-registering macro, you can free the original [SslLibCallback](#) structure.

The protocol for the callback functions is described in [SslCallbackFunc\(\)](#), in [Chapter 80, "SSL Functions."](#)

## SslCipherSuiteInfo Struct

**Purpose** Structure that contains information about the cipher suite that's being used. The structure is stored in the [CipherSuiteInfo](#) attribute.

**Prototype**

```
typedef struct SslCipherSuiteInfo_st {
    UInt8  cipherSuite[2];
    UInt16 cipher;
    UInt16 digest;
    UInt16 keyExchange;
    UInt16 authentication;
    UInt16 version;
    UInt16 cipherBitLength;
    UInt16 cipherKeyLength;
    UInt16 keyExchangeLength;
```

## SSL Structures and Data Types

### *SslCipherSuiteInfo*

---

```
    UInt16  authenticationLength;  
    UInt16  export;  
} SslCipherSuiteInfo;
```

The fields are:

---

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cipherSuite | <p>A two-byte value that represents the current cipher suite. The possible values, encoded as constants, are:</p> <p><b>0:</b> No cipher suite is being used.</p> <p><b>sslCs_RSA_RC4_56_SHA1:</b> Secure Hash Algorithm-1, 56-bit</p> <p><b>sslCs_RSA_RC4_128_SHA1:</b> Secure Hash Algorithm-1, 128-bit.</p> <p><b>sslCs_RSA_RC4_40_MD5:</b> Rivest Message Digest 5, 40-bit.</p> <p><b>sslCs_RSA_RC4_128_MD5:</b> Rivest Message Digest 5, 128-bit.</p> |
| cipher      | <p>A constant that represents the cipher that's being used for this connection:</p> <p><b>sslCsiCipherNull:</b> No cipher currently set.</p> <p><b>sslCsiCipherRc4:</b> RSA RC4.</p>                                                                                                                                                                                                                                                                       |
| digest      | <p>A constant that represents the message digest format.:</p> <p><b>sslCsiDigestNull:</b> No message digest.</p> <p><b>sslCsiDigestMd2:</b> Rivest Message Digest 2.</p> <p><b>sslCsiDigestMd5:</b> Rivest Message Divest 5.</p> <p><b>sslCsiDigestSha1:</b> Secure Hash Algorithm-1.</p>                                                                                                                                                                  |
| keyExchange | <p>A constant that represents the key exchange type that's being used:</p> <p><b>sslCsiKeyExchNull:</b> No key exchange.</p> <p><b>sslCsiKeyExchRsa:</b> RSA.</p>                                                                                                                                                                                                                                                                                          |

---

---

|                      |                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authentication       | A constant that represents the authentication type that's being used:<br><br><b>sslCsiAuthNull:</b> No key exchange.<br><b>sslCsiAuthRsa:</b> RSA.                                         |
| version              | The SSL version number.                                                                                                                                                                    |
| cipherBitLength      | The length of the material used for encryption key generation, in bits. For export ciphers this will be either 40 or 56 bits.                                                              |
| cipherKeyLength      | The length of the encryption key that's generated, in bits. For an export RC4 cipher, the cipherKeyLength is 128.                                                                          |
| keyExchangeLength    | The length of the public key used to establish a shared secret, in bits.                                                                                                                   |
| authenticationLength | The length of the public key used to ensure that the key exchange wasn't tampered with, in bits. For export ciphers, the keyExchangeLength is often shorter than the authenticationLength. |
| export               | A boolean value: 1 if an export cipher is being used; 0 otherwise.                                                                                                                         |

---

The list of possible cipher suites can be retrieved from the [CipherSuites](#) attribute. The suite that's currently being used is given by the [CipherSuite](#) attribute.

### SslExtendedItem Struct

**Purpose** Structure that's used to describe a single certificate-related item. Every `SslExtendedItem` has a distinct (pre-defined) "extended item type." The location of the item's data is indicated by the structure—the data isn't stored in the structure.

You never create `SslExtendedItem` structures yourself. The objects that relate to a particular certificate are collected into an

# SSL Structures and Data Types

## SslExtendedItem

---

[SslExtendedItems](#) structure and returned to you (principally) by your verify callback function.

**Prototype**    typedef struct SslExtendedItem\_st {  
                  UInt16    type;  
                  UInt16    field;  
                  UInt16    dataType;  
                  UInt16    len;  
                  UInt32    offset;  
                  } SslExtendedItem;

The fields are:

---

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type     | The extended item type, one of:<br><br><b>sslExItemTypeX509:</b> X.509 Certificate<br><b>sslExItemTypeRSA:</b> RSA public key<br><b>sslExItemTypeRDN:</b> An X.509 Relative Distinguished Name (RDN). This is the certificate's name. Each certificate contains two names, the <i>Subject</i> of the certificate and the <i>Issuer</i> of the certificate. Both are encoded as RDNs that contain multiple fields.<br><br><b>sslExItemTypeX509Ex:</b> X.509 certificates can contain multiple "extensions." This type is used to specify that the item is a certificate extension. |
| field    | Type-specific value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| dataType | The encoding for the item's data. For the SSL library, the value is one of the ASN.1 encoding types, as listed in SslLibAsn1.h. The encoding is relevant if you're trying to display the data bytes.                                                                                                                                                                                                                                                                                                                                                                              |

|                     |                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>len</code>    | Number of data bytes.                                                                                                                                                     |
| <code>offset</code> | Location of the data itself, as an offset in bytes from the beginning of the <a href="#">SslExtendedItems</a> structure that contains this <code>SslExtendedItem</code> . |

## SslExtendedItems Struct

**Purpose** Structure that contains a set of related data items that pertain to an SSL certificate or other cryptographic entity. The `SslExtendedItems` structure is used as part of the [SslVerify](#) structure, and is used as the type of the [PeerCert](#) attribute.

The `SslExtendedItems` structure is used by the SSL library to return information to your application; you never create and populate an `SslExtendedItems` structure yourself.

**Prototype**

```
typedef struct SslExtendedItems_st
{
    UInt32    length;
    UInt32    num;
    SslExtendedItem  eitem[1];
} SslExtendedItems;
```

The fields are:

|                     |                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>length</code> | Total length of the structure, in bytes.                                                                                  |
| <code>num</code>    | Number of elements in the <code>eitem</code> array.                                                                       |
| <code>eitem</code>  | Individual data items (these are the “related data items” mentioned above). The array contains <code>num</code> elements. |

The items in the `eitem` array needn’t all be the same “extended item type” (as defined in [SslExtendedItem](#)). For example, the `SslExtendedItems` structure for a certificate typically contains an `sslExItemTypeX509` item, an `sslExItemTypeRSA`, and an `sslExItemType` (for the subject name).

**SslIoBuf Struct**

**Purpose**      Structure that represents a data I/O operation. It’s passed to your info callback function as data is being read or written.

**Prototype**    `typedef struct {  
                 SslContext *ssl;  
                 UInt8 *ptr;  
                 UInt32 outNum;  
                 UInt32 inNum;  
                 UInt32 max;  
                 UInt32 err;  
                 UInt32 flags;  
             } SslIoBuf;`

You can ask for the info callback function to be invoked just before data is read, just after it’s read, just before it’s written, and just after it’s written. You set the [InfoInterest](#) attribute to register for these four events.

Most of the SslIoBuf fields depend on which of these four events is being described:

**Fields**

|        |                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctx    | The SSL context that performed the operation.                                                                                                                                                           |
| ptr    | A pointer to the data that was just read, or that’s about to be written. For “before read” and “after write” events, the buffer should be empty.                                                        |
| outNum | The number of bytes that were just read or written. For the “before” events, this field is set to 0.                                                                                                    |
| inNum  | The number of bytes that are about to be read or written. For the “before read” case, this is the minimum number of bytes that the context wants to read—the actual number of bytes read may be larger. |
| max    | This is valid for the “before read” event only. It’s set to the maximum number of bytes that can be read during the current operation.                                                                  |

|       |                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------|
| error | This is set to the error code that was returned by a read operation. It's only valid for the "after" events. |
| flags | Currently ignored.                                                                                           |

The information in this structure is provided for debugging and informational purposes only. You could use it, for example, to display the progress of an I/O operation.

### SslLibCallback Struct

|                    |                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Structure that represents a secure socket.                                                                                                                                                                                                                                                                             |
| <b>Declared In</b> | SslLib.h                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>typedef struct {     void *reserved;     SslLibCallbackFunc callback;     void *data;     SslContext *ssl; } SslLibCallback</pre>                                                                                                                                                                                 |
| <b>Fields</b>      | <p><b>callback</b> A pointer to a callback function.</p> <p><b>data</b> A pointer to data that's passed to the function when it's invoked.</p> <p><b>ssl</b> The SSL context to which the callback applies, or NULL if the structure is owned by an SslLib object.</p> <p><b>reserved</b> Reserved for future use.</p> |

To register a callback function, create a SslLibCallback structure, fill out the callback and data fields and pass the structure to one of the [SslCallbackFunc\(\)](#) functions. The structure is copied into the context, and the ssl field is properly set (in the copy).

It's the caller's responsibility to free the original SslLibCallback structure. The same SslLibCallback structure can be used to set more than one callback function.

For more information, see [SslCallbackFunc\(\)](#) in [Chapter 80](#), “[SSL Functions](#).”

**SslSession Struct**

**Purpose**      Structure that represents the current SSL session.

**Prototype**    `typedef struct SslSession_st`  
                 `{`  
                     `UInt32    length;`  
                     `UInt16    version;`  
                     `unsigned char    cipherSuite[2];`  
                     `unsigned char    compression;`  
                     `unsigned char    sessionId[33];`  
                     `unsigned char    masterSecret[48];`  
                     `unsigned char    time[8];`  
                     `unsigned char    timeout[4];`  
                     `UInt16    certificateOffset;`  
                     `UInt16    extraData;`  
                 `} SslSession;`

A context’s `SslSession` is populated when you call [SslOpen\(\)](#). You can retrieve a context’s `SslSession` structure and modify it directly—particularly if you want to set the fields that are reserved for application use. To retrieve the `SslSession`, call the [SslContextGet\\_SslSession](#) macro. Keep in mind that this gives you a pointer to the context’s internal [SslSession](#) attribute. If you want to store the `SslSession`, you must copy the attribute’s data.

The fields are:

---

|                          |                                                                                    |
|--------------------------|------------------------------------------------------------------------------------|
| <code>length</code>      | The total size of the structure, in bytes.                                         |
| <code>version</code>     | Version number of the SSL protocol that’s being us the session is using cleartext. |
| <code>cipherSuite</code> | Cipher suite that’s being used. See the <a href="#">CipherSui</a> attribute.       |
| <code>compression</code> | The name of the compression scheme that’s being                                    |

---

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sessionId</code>         | Session identification number. The ID value may be as many as 32 bytes long; the first byte gives the valid bytes.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>masterSecret</code>      | The value of the “master secret” that was established during the SSL handshake.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>time</code>              | Used to record the time that the session started in local time representation. The format can be any that fits in eight bytes. Unused by the SSL library; an application can use this field as it wishes.                                                                                                                                                                                                                                                                                                         |
| <code>timeout</code>           | The number of seconds that the session should be valid. The timeout field is also unused by the SSL library. Use it as you wish.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>certificateOffset</code> | Offset, in bytes, from the start of the structure <a href="#">SslExtendedItems</a> to the start of the certificate. The field is provided for the application's convenience. The SSL library doesn't actually use the certificate: If you want to cache the server's certificate, you have to retrieve the data through the <a href="#">PeerC</a> structure, extend the size of the <code>SslSession</code> structure, copy the certificate data, and then set the <code>certificateOffset</code> field yourself. |
| <code>extraData</code>         | Offset, in bytes, from the start of the structure to the start of the data that the application keeps for itself. This field is similar to the <code>certificateOffset</code> field: You have to copy the data, and mark the data yourself.                                                                                                                                                                                                                                                                       |

---

### SslSocket Struct

**Purpose** The `SslSocket` structure contains information about the socket that's being used in the network connection. The structure is defined as:

**Prototype**

```
typedef struct {
    NetSocketRef  socket;
    Int16         flags;
    UInt16        addrLen;
```

## SSL Structures and Data Types

### *SslSocket*

---

```
Err    err;  
Int32  timeout;  
NetSocketAddrType  addr;  
}  SslSocket;
```

You can create your own `SslSocket` structure and add its data to a context through the [SslContextSet\\_IoStruct](#) macro. When you do this, the data in your structure is copied into a structure that's held by the context. Note, however, that the `socket` field isn't copied. To set the socket, use [SslContextSet\\_Socket](#).

The argument values that you pass to [SslSend\(\)](#) and [SslReceive\(\)](#) are used to modify the context's `SslSocket` structure. If, for example, you create an `SslSocket` with a particular timeout value, set it in a context, and then call [SslSend\(\)](#) with a different timeout value (passed as an argument), the latter timeout is recorded in the context's `SslSocket` structure, overriding your original setting.

To retrieve a pointer to the context's `SslSocket`, call [SslContextGet\\_IoStruct](#).

The fields are:

---

|         |                                                                                                                                                                                                                                                                                                    |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| socket  | Socket identifier, as created and returned by <code>NetLibSocketOpen</code> . The SSL library doesn't open or connect the socket for you; all socket operations other than reading and writing data must be done through net library calls.                                                        |
| flags   | You never set the <code>socket</code> field directly; use the <a href="#">SslContextSet_Socket</a> macro, instead.<br>Options that control a socket's I/O operations. See <a href="#">I/O Flags</a> in <a href="#">Chapter 61, "Net Library,"</a> on page 1349 for a description of these options. |
| addr    | The most recent address that the socket read from or wrote to.                                                                                                                                                                                                                                     |
| addrLen | The length, in bytes, of the <code>addr</code> field.                                                                                                                                                                                                                                              |

|                      |                                                            |
|----------------------|------------------------------------------------------------|
| <code>err</code>     | The most recent socket error.                              |
| <code>timeout</code> | The socket's I/O operation timeout value, in system ticks. |

---

### SslVerify Struct

**Purpose** Structure that's passed to a verify callback function to provide information about a certificate that's being verified. This happens when the verification process hits a snag, giving your app a chance to handle the problem. The callback is also invoked when the process has successfully completed.

**Prototype**

```
typedef struct SslVerify_st
{
    SslExtendedItems *certificate;
    SslExtendedItems *fieldItems;
    UInt32 field;
    SslExtendedItems *ex;
    UInt32 depth;
    UInt32 state;
} SslVerify;
```

The fields are:

---

|                          |                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>certificate</code> | Points to the certificate that's being verified.                                                                                                                                                                         |
| <code>fieldItems</code>  | <code>fieldItems</code> is an array of extended items;                                                                                                                                                                   |
| <code>field</code>       | <code>field</code> is an index into <code>fieldItems</code> . The <a href="#">SslExtendedItems</a> that's located at <code>fieldItems[ field ]</code> contains the set of items that's causing the problem. (See below.) |

## SSL Structures and Data Types

### *SslVerify*

---

|       |                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ex    | If this is an extension error, the ex field contains the data element of the X509 extension that failed.                                                                                               |
| depth | This is the level of the certificate being processed, where 0 is the server's certificate, and higher numbers are certificates along the "certificate chain" that leads to a trusted root certificate. |

---

The list of [SslExtendedItem](#) elements that the [SslExtendedItems](#) object located at `fieldItems[ field ]` contains depends on the error flavor:

**Table 81.1**

| Flavor                               | Contents                                                         |
|--------------------------------------|------------------------------------------------------------------|
| sslErrVerifyBadSignature             | The server's certificate, which contains the public key entries. |
| sslErrVerifyNoTrustedRoot            | NULL                                                             |
| sslErrVerifyNotAfter                 | sslExItemTypeX509,<br>asn1FldX509NotAfter                        |
| sslErrVerifyNotBefore                | sslExItemTypeX509,<br>asn1FldX509NotBefore.                      |
| sslErrVerifyConstraintViolation      | asn1ExItemTypeX509Ex (but<br>see below)                          |
| sslErrVerifyUnknownCriticalExtension | asn1ExItemTypeX509Ex (but<br>see below)                          |
| sslErrOk                             | NULL                                                             |

---

The `asn1ExItemTypeX509Ex` item needs to be decoded in order to be used. The item contains the "object identifier" part of a certificate extension. The item in the next field (i.e. `fieldItems[ field+1 ]`) depends on the item's `dataType` field: If it's `asn1Boolean`, then the "+1" item contains the extension's optional Boolean "this is a critical extension" field, otherwise it

contains the extension data itself. If “+1” contains the Boolean, than “+2” is the data.

The SSL library attempts to interpret only critical extensions, so the critical field should always be present. If a critical extension isn’t understood, the certificate should be rejected.

## SSL Structures and Data Types

*SslVerify*

---

# SSL Attributes and Macros

---

As described in [Chapter 81](#), “[SSL Structures and Data Types](#),” the [SslLib](#) and [SslContext](#) objects list and describe the properties, or **attributes**, of an SSL context.

There are a number of SSL attributes: Some provide general-purpose information that any SSL session needs, some are used only for specific protocols, some are provided for debugging purposes, and so on.

Associated with each attribute is a set of macros that get and set the attribute’s value.

This chapter lists and describes the SSL attributes, how they’re used, the values that they take (including defaults), and the macros that access them:

- “[SSL Macro Names](#)” explains how the macro names are formed, and how they correspond to the SSL attributes.
- “[SSL Attribute Data Types](#)” talks about the types of data an attribute can represent.
- “[SSL Macro Pseudo-Protocol](#)” provides a pseudo-protocol for the macros.
- “[SSL Attributes](#)” lists the attributes in alphabetical order.
- “[SSL Attribute Constants](#)” is a list of constants that represent the attributes in the attribute-setting functions (which you can use instead of the macros, although it isn’t recommended; the functions are explained below).

## SSL Macro Names

An SSL attribute is accessed through a set of (as many as) four macros: There's a macro that lets you set an attribute's value in an [SslLib](#), another that sets the attribute's value in an [SslContext](#), and two others that retrieve attribute values from these objects.

The names of the four macros for a given attribute follow this pattern:

- `SslLibSet_Attribute` sets the attribute in an [SslLib](#).
- `SslLibGet_Attribute` gets the attribute from an [SslLib](#).
- `SslContextSet_Attribute` sets the attribute in an [SslContext](#).
- `SslContextGet_Attribute` gets the attribute from an [SslContext](#).

For example, the four macros that set and get the [Mode](#) attribute are:

- `SslLibSet_Mode`
- `SslLibGet_Mode`
- `SslContextSet_Mode`
- `SslContextGet_Mode`

Note that not all attributes require all four macros: Some attributes are read-only, while others apply only to [SslContext](#) objects.

The macros are covers for the eight attribute-setting functions described in [Chapter 80, "SSL Functions,"](#) on page 2043. It's recommended that you use the macros rather than the functions, but you should be aware of the functions' existence.

## SSL Attribute Data Types

An SSL attribute is either an integer or a pointer. For pointer attributes, the type of the pointed-to data depends on the attribute. The descriptions below explicitly state these data types. (The macro declarations in the `SslLibMac.h` file don't include the data types.)

When setting a pointer attribute, the pointed-to data is (almost always) copied into the [SslLib](#) or [SslContext](#). The original data needn't be preserved—the caller is free to destroy the original data

when the pointer-setting macro returns. The exceptions to this rule are pointed out in the macro descriptions, below.

To retrieve a pointer attribute, you pass in the address of a pointer; the macro will reset the pointer to data that belongs to the [SslLib](#) or [SslContext](#). You mustn't free or otherwise modify this data.

The macros that set and get integer attributes are defined in terms of the [SslLibSetLong\(\)](#), [SslLibGetLong\(\)](#), [SslContextSetLong\(\)](#), and [SslContextGetLong\(\)](#) functions, described in [Chapter 80, "SSL Functions,"](#) on page 2043. The pointer-accessing macros are covers for an analogous set of functions ([SslLibSetPtr\(\)](#), *et al.*). You should rarely need to call these functions directly—they're meant to be called by the attribute macros.

## SSL Macro Pseudo-Protocol

This section provides pseudo-protocol for the attribute macros.

### **SslContextGet\_Attribute (integer version) Macro**

|                   |                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Returns the value of an integer-valued attribute that's stored in an <a href="#">SslContext</a> object. This is a cover for the <a href="#">SslContextGetLong()</a> function. |
| <b>Prototype</b>  | <pre>Int32 SslContextSet_Attribute ( UInt16 libRef,<br/>                               SslContext *context )</pre>                                                            |
| <b>Parameters</b> | <p>→ <i>libRef</i><br/>(68k only) SSL library reference number.</p> <p>→ <i>context</i><br/>The <a href="#">SslContext</a> that owns the attribute.</p>                       |
| <b>Returns</b>    | Returns the attribute's value, or a negative-valued error code as described in <a href="#">SslContextGetLong()</a> .                                                          |

## SSL Attributes and Macros

*SslContextGet\_Attribute (pointer version)*

---

### **SslContextGet\_Attribute (pointer version) Macro**

- Purpose** Gets a pointer-valued attribute from an [SslContext](#) object. This is a cover for the [SslContextGetPtr\(\)](#) function.
- Prototype**

```
Int32 SslContextGet_Attribute ( UInt16 libRef,
                               SslContext *context, void **data )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *context*  
The [SslContext](#) that owns the attribute.
  - *data*  
The macro resets \*data so it points to the attribute's data. Unless otherwise noted, the pointed-to data belongs to the [SslContext](#) and shouldn't be freed.
- Returns** Returns 0 upon success; see [SslContextGetPtr\(\)](#) for error return values.

### **SslLibSet\_Attribute (integer version) Macro**

- Purpose** Sets an integer-valued attribute in an [SslContext](#) object. This is a cover for the [SslLibSetLong\(\)](#) function.
- Prototype**

```
Err SslLibSet_Attribute ( UInt16 libRef,
                          SslContext *context, Int32 value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *context*  
The [SslContext](#) that owns the attribute.
  - *value*  
The value you want to set the attribute to.
- Returns** Returns 0 upon success; see [SslLibSetLong\(\)](#) for error return values.

## **SslContextSet\_Attribute (pointer version) Macro**

- Purpose** Sets a pointer-valued attribute in an [SslContext](#) object. This is a cover for the [SslContextSetPtr\(\)](#) function.
- Prototype** `Err SslContextSet_Attribute ( UInt16 libRef,  
SslContext *context, void *data )`
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *context*  
The [SslContext](#) that owns the attribute.
  - *data*  
A pointer to the data that you want to set.
- Returns** Returns 0 upon success; see [SslContextSetPtr\(\)](#) for error return values.
- Comments** The data from *data* is copied into the [SslContext](#). You can free the original data after the macro returns.

## **SslLibGet\_Attribute (integer version) Macro**

- Purpose** Returns the value of an integer-valued attribute that's stored in an [SslLib](#) object. This is a cover for the [SslLibGetLong\(\)](#) function.
- Prototype** `Int32 SslLibSet_Attribute ( UInt16 libRef,  
SslLib *lib )`
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *lib*  
The [SslLib](#) that owns the attribute.
- Returns** Returns the attribute's value, or a negative-valued error code

## SSL Attributes and Macros

*SslLibGet\_Attribute (pointer version)*

---

### **SslLibGet\_Attribute (pointer version) Macro**

- Purpose** Gets a pointer-valued attribute from an [SslLib](#) object. This is a cover for the [SslLibGetPtr\(\)](#) function.
- Prototype**

```
Int32 SslLibGet_Attribute ( UInt16 libRef,  
                           SslLib *lib, void **data )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *lib*  
The [SslLib](#) that owns the attribute.
  - *data*  
The macro resets \*data so it points to the attribute's data. Unless otherwise noted, the pointed-to data belongs to the [SslLib](#) and shouldn't be freed.
- Returns** Returns 0 upon success; see [SslLibGetPtr\(\)](#) for error return values.

### **SslLibSet\_Attribute (integer version) Macro**

- Purpose** Sets an integer-valued attribute in an [SslLib](#) object. This is a cover for the [SslLibSetLong\(\)](#) function.
- Prototype**

```
Err SslLibSet_Attribute ( UInt16 libRef,  
                          SslLib *lib, Int32 value )
```
- Parameters**
- *libRef*  
(68k only) SSL library reference number.
  - *lib*  
The [SslLib](#) that owns the attribute.
  - *value*  
The value you want to set the attribute to.
- Returns** Returns 0 upon success; see [SslLibSetLong\(\)](#) for error return values.

**SslLibSet\_Attribute (pointer version) Macro**

|                   |                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Sets a pointer-valued attribute in an <a href="#">SslLib</a> object. This is a cover for the <a href="#">SslLibSetPtr()</a> function.                                                                                |
| <b>Prototype</b>  | <code>Err SslLibSet_Attribute ( UInt16 libRef,<br/>                          SslLib *lib, void *data )</code>                                                                                                        |
| <b>Parameters</b> | <p>→ <i>libRef</i><br/>(68k only) SSL library reference number.</p> <p>→ <i>lib</i><br/>The <a href="#">SslLib</a> that owns the attribute.</p> <p>→ <i>data</i><br/>A pointer to the data that you want to set.</p> |
| <b>Returns</b>    | Returns 0 upon success; see <a href="#">SslLibSetPtr()</a> for error return values.                                                                                                                                  |
| <b>Comments</b>   | The data from <i>data</i> is copied into the <a href="#">SslLib</a> . You can free the original data after the macro returns.                                                                                        |

## SSL Attributes

**AppInt32**

Convenient Int32 datum that the application can use for whatever purpose it wants—as an object ID, for example. Note that the value is *not* copied from an [SslLib](#) into the [SslContexts](#) that it spawns.

```

type:      Int32
macros:    SslLibSet_AppInt32
           SslLibGet_AppInt32
           SslContextSet_AppInt32
           SslContextGet_AppInt32

```

### AppPtr

Convenient pointer that the application can use for whatever purpose it wants.

type:            (void \*)

The application retains ownership of the pointed-to data. The data is *not* copied into the [SslLib](#) or [SslContext](#).

macros:        SslLibSet\_AppPtr  
                SslLibGet\_AppPtr  
                SslContextSet\_AppPtr  
                SslContextGet\_AppPtr

### AutoFlush

Enables/disables automatic flushing of data after an [SslSend\(\)](#) or [SslWrite\(\)](#).

type:            Int32

values:        0:     Autoflush is turned off.

                1:     Autoflush is turned on.

default:       1 (autoflush on)

macros:        SslLibSet\_AutoFlush  
                SslLibGet\_AutoFlush  
                SslContextSet\_AutoFlush  
                SslContextGet\_AutoFlush

When enabled, [SslFlush\(\)](#) is automatically called after every call to [SslSend\(\)](#) and [SslWrite\(\)](#). If you have autoflush disabled, you have to call the [SslFlush\(\)](#) function yourself. You don't have to call it after *every* [SslSend\(\)](#) or [SslWrite\(\)](#), but you *do* have to call it before the [SslContext](#)'s write buffer fills up.

The write buffer's size is given by [WbufSize](#); the amount of data that's currently in the buffer is given by [WriteBufPending](#)

## BufferedReuse

Allows the last message in an SSL handshake to be buffered. This only applies if [SessionReused](#) is true (non-zero).

type:        Int32

values:     **0:**     Don't buffer the last handshake message.

**non-zero:** Buffer the last handshake message.

macros:     SslContextGet\_BufferedReuse

As described in [SessionReused](#), the handshake involved in re-establishing a previous session can be a truncated version of a normal handshake. At the end of the truncated handshake, the SSL library sends a message to the server. The `BufferReuse` attribute, if enabled, will buffer the last message of the reused handshake instead of sending it over the network. The message will be sent when the application sends its first “real” data.

If you have `BufferReuse` enabled, you must make sure that the final handshake message actually gets sent before reading any incoming data.

There are security implications, here, in that a man-in-the-middle attack could only be detected once the first data bytes are read from the server. In other words, an attacker could have read all the bytes in the first “real data” message sent to the server. For this reason this attribute should not normally be used.

## CipherSuite

Represents the cipher suite that's currently in use in this context. [SslContext](#) only, read only.

## SSL Attributes and Macros

### *CipherSuiteInfo*

---

type: (UInt8 \*)

values: Each suite is represented by a two-byte value.

0: No cipher suite is being used.

**sslCs\_RSA\_RC4\_56\_SHA1:** Secure Hash Algorithm-1, 56-bit

**sslCs\_RSA\_RC4\_128\_SHA1:** Secure Hash Algorithm-1, 128-bit.

**sslCs\_RSA\_RC4\_40\_MD5:** Rivest Message Digest 5, 40-bit.

**sslCs\_RSA\_RC4\_128\_MD5:** Rivest Message Digest 5, 128-bit.

macros: SslContextGet\_CipherSuite

**See Also** [CipherSuites](#)

## CipherSuiteInfo

Returns information about the cipher suite or certificate that's currently being used. [SslContext](#) only, read only.

type: ([SslCipherSuiteInfo](#) \*)

The [SslCipherSuiteInfo](#) structure must be allocated before it's passed in. The caller retains ownership of the structure.

values: The structure is populated by the context. For information on what the structure contains, see [SslCipherSuiteInfo](#).

macros: SslContextGet\_CipherSuiteInfo

To return *just* the cipher suite (without the surrounding information), get the [CipherSuite](#) attribute.

## CipherSuites

Contains a list of cipher suites that the client supports, in order of preference.

type: (UInt8 \*)

values: Each element in the list takes two bytes. The first two byte element give the sizes of the rest of the list, in bytes (i.e. the “size bytes” themselves aren’t counted in the measurement). The rest of the list is made up of the following (two-byte) constants:

```
sslCs_RSA_RC4_128_MD5
sslCs_RSA_RC4_128_SHA1
sslCs_RSA_RC4_56_SHA1
sslCs_RSA_RC4_40_MD5
```

The data in the list is given in network byte order.

default: The default list contains {0x00, 0x08} followed by the suites listed above, in order. To restore the default list, pass a NULL pointer.

macros: SslLibSet\_CipherSuites  
SslLibGet\_CipherSuites  
SslContextSet\_CipherSuites  
SslContextGet\_CipherSuites

As an example, the following code creates a list of the strong encryption suites (only) and sets it into an [SslLib](#):

---

```
static UInt8 cipherSuites[]={
    0x00,0x04,
    sslCs_RSA_RC4_128_MD5,
    sslCs_RSA_RC4_128_SHA1
};

SslLibSet_CipherSuites(lib,cipherSuites);
```

---

## SSL Attributes and Macros

### Compat

---

The cipher suites list is used when the client and server negotiate for an acceptable suite. The suite that's chosen is represented by the [CipherSuite](#) attribute.

## Compat

Allows compatibility with malformed or incorrect SSL messages sent from the server

type: Int32

values: 0: No incompatibility allowed.

If non-zero, the value should be a combination of the following flags.

**sslCompatReuseCipherBug:** Allows servers to change cipher suites on session-reuse.

**sslCompatNetscapeCaDnBug:** Supports old versions of Netscape servers that encode "Distinguished Names" certificates incorrectly. (Note that this isn't currently an issue since the SSL library doesn't support client certificates.)

**sslCompat1RecordPerMessage:** Ensures that SSL messages aren't broken across records. (Some servers don't like to receive SSL messages separated into multiple SSL records.)

**sslCompatBigRecords:** Supports records larger than 16k bytes. (In SSLv3, record size is normally limited to 16k.)

**sslCompatAll:** Enables all the foregoing.

default: 0

macros: SslLibSet\_Compat

SslLibGet\_Compat

SslContextSet\_Compat

SslContextGet\_Compat

## DontSendShutdown

Avoid sending a shutdown message.

type:        Int32

values:      **0:**        Send the shutdown message.  
              **non-zero:** Don't send the shutdown message.

default:     0

macros:      SslLibSet\_DontSendShutdown  
              SslLibGet\_DontSendShutdown  
              SslContextSet\_DontSendShutdown  
              SslContextGet\_DontSendShutdown

When [SslClose\(\)](#) is called, the two SSL endpoints swap shutdown messages. You can suppress transmission of the local message by setting this attribute.

To ignore the remote shutdown message, set the [DontWaitForShutdown](#) attribute.

## DontWaitForShutdown

Avoid waiting for reception of the server's shutdown message.

type:        Int32

values:      **0:**        Wait for the shutdown message.  
              **non-zero:** Don't wait the shutdown message.

default:     0

macros:      SslLibSet\_DontWaitForShutdown  
              SslLibGet\_DontWaitForShutdown  
              SslContextSet\_DontWaitForShutdown  
              SslContextGet\_DontWaitForShutdown

See [DontSendShutdown](#) for details.

## Error

Stores the most recent fatal error code. [SslContext](#) only.

type:        Int32

values:      0:    No error

**non-zero:** An error occurred somewhere up to here.  
Note that SslErrIo errors are exempt (they're not considered to be fatal).

default:     0

macros:      SslContextSet\_Error

SslContextGet\_Error

After you read an Error value, you should set the attribute's value back to 0. The value is reset during an SSL Reset, but it otherwise holds the latest fatal error code.

## HsState

Current SSL state. [SslContext](#) only, read only. Used primarily for debugging.

type:        Int32

values:      Defined by the SSL protocol.

macros:      SslContextGet\_HsState

## InfoCallback

Identifies the callback function that's called at particular moments in an SSL transaction.

type:        ([SslCallback](#) \*)

default: none

macros: SslLibSet\_InfoCallback  
SslLibGet\_InfoCallback  
SslContextSet\_InfoCallback  
SslContextGet\_InfoCallback

If you set the InfoCallback attribute, you must also set the [InfoInterest](#) attribute to register for the notifications that you want.

See the [SslCallbackFunc\(\)](#) description in [Chapter 80, “SSL Functions,”](#) on page 2043 for more information about the callback functions.

## **InfoInterest**

Specifies the events for which the callback function identified by the [InfoCallback](#) attribute will be called.

## SSL Attributes and Macros

### *InfoInterest*

---

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type:    | Int32                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| values:  | <p>The value is formed as a combination of the following (or 0 if you don't want your callback to be called):</p> <p><b>sslFlgInfoAlert:</b> The callback wants to know about alert notifications. In an alert, the function receives <code>sslArgInfoAlert</code> as its command argument.</p> <p><b>sslFlgInfoHandshake:</b> The callback wants to know about handshake notifications (<code>sslArgInfoHandshake</code>).</p> <p><b>sslFlgInfoIO:</b> The callback wants to be called before and after each <a href="#">SslCallback</a> operation (<code>sslArgInfoReadBefore</code>, <code>sslArgInfoReadAfter</code>, <code>sslArgInfoWriteBefore</code>, <code>sslArgInfoWriteAfter</code>).</p> <p><b>sslFlgInfoCert:</b> The callback wants to know about certificate notifications (<code>sslArgInfoCert</code>).</p> |
| default: | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| macros:  | <code>SslLibSet_InfoInterest</code><br><code>SslLibGet_InfoInterest</code><br><code>SslContextSet_InfoInterest</code><br><code>SslContextGet_InfoInterest</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

For these to be effective, you must set an info callback function (see [InfoCallback](#)).

For more information on how the callback functions work, and for detailed specifications of the command values referred to above, see the [SslCallbackFunc\(\)](#) description in [Chapter 80, "SSL Functions,"](#) on page 2043.

## IoTimeout

Amount of time that an I/O operation should wait for a response from the other side of the network connection before it gives up and returns an error. The timeout is measured in ticks.

type:           Int32  
values:         [0, 0xffffffff].  
default:        10 seconds  
macros:         SslContextSet\_IoTimeout  
                 SslContextGet\_IoTimeout

Individual SSL library functions can specify their own timeout values. In the absence of a timeout specification, the `IoTimeout` value is used.

## IoFlags

Socket I/O flags that are used by the data read and write functions. [SslContext](#) only.

type:           Int32  
values:         See the “[I/O Flags](#)” on page 1356 for a list of these flags. `netIOFlagOutOfBand` and `netIOFlagPeek` don’t apply; they’re twiddled out of the value you supply.  
default:        none  
macros:         SslContextSet\_IoFlags  
                 SslContextGet\_IoFlags

## IoStruct

[SslSocket](#) structure that holds arguments that are passed to the underlying net library functions. [SslContext](#) only.

## SSL Attributes and Macros

*LastAlert*

---

type:        ([SslSocket](#) \*)  
values:      See [SslSocket](#).  
default:     ([SslSocket](#) \*) NULL  
macros:      SslContextSet\_IoStruct  
              SslContextGet\_IoStruct

When you call `SslContextSet_IoStruct`, the `socket` field of the [SslSocket](#) that you pass in is ignored. Use the [Socket](#) attribute to set the socket.

The structure's other fields correspond to the arguments to the [SslSend\(\)](#) and [SslReceive\(\)](#) functions (which see for details). When you call one of these functions, the arguments that you pass are copied into the context's [SslSocket](#) structure. Thus, the [SslSocket](#) configuration that you set through `SslContextSet_IoStruct` may be updated when you call an I/O function.

## LastAlert

Most recent fatal error code. [SslContext](#) only, read only.

type:        Int32  
values:      See the `sslAlertType` constants in `SslLibMac.h`.  
default:     0  
macros:      SslContextGet\_LastAlert

An alert is an error or status code that's sent by the server. Alerts can be fatal or non-fatal. Fatal alerts are in the form 0x02xx; non-fatal alerts are 0x01xx, as shown below:

---

```
Int32 alert;  
  
SslContextGet_LastAlert( context, &alert);  
  
if ( alert != 0 ) {  
    if ( alert & 0x0f00 == 0x0200 )  
        /* fatal */
```

```

    else if ( alert & 0x0f00 == 0x0100 )
        /* non-fatal */
    else
        /* undefined */
}

```

---

## LastApi

Represents the most recently called SSL library function. [SslContext](#) only, read only.

type: Int32

values:

- sslLastApiNone:** No SSL library function call in this context since the last SSL reset.
- sslLastApiRead:** The previous function was [SslOpen\(\)](#).
- sslLastApiRead:** The previous function was [SslRead\(\)](#), [SslPeek\(\)](#), or [SslReceive\(\)](#).
- sslLastApiWrite:** The previous function was [SslWrite\(\)](#) or [SslSend\(\)](#).
- sslLastApiFlush:** The previous function was [SslFlush\(\)](#).
- sslLastApiShutdown:** The previous function was [SslClose\(\)](#).

macros: SslContextGet\_LastApi

## LastIO

Represents the nature of the previous I/O operation. [SslContext](#) only, read only.

## SSL Attributes and Macros

### *Mode*

---

type:       Int32

values:     **sslLastIoNone:**   There is yet to be an I/O operation in this context since the last SSL reset.

**sslLastIoRead:**   The previous I/O operation was a read.

**sslLastIoWrite:**  The previous I/O operation was a write.

default:    sslLastIoNone

macros:     SslContextGet\_LastIO

This attribute can be useful when you're determining the reason for an error.

### **Mode**

Turns SSL on and off.

type:       Int32

values:     **sslModeClear:**   SSL is turned off.

**sslModeSsl:**     SSL is turned on

**sslModeSslClient:** SSL is turned on, and this endpoint is a client.

**sslModeFlush:**   Data-clearing flag. If present, the context's internal data buffers are cleared (the data is lost). This flag is applicable to [SslContexts](#) only.

default:    sslModeSslClient

macros:     SslLibSet\_Mode

            SslLibGet\_Mode

            SslContextSet\_Mode

            SslContextGet\_Mode

`sslModeSsl` and `sslModeSslClient` are essentially the same; the only difference is that the latter explicitly declares the object to represent the client side of the connection. In Palm OS 5, SSL endpoints are always clients.

When set to `sslModeClear`, SSL is bypassed. This lets you write your application with the SSL library API and still perform normal (non-SSL) data transfers. Your application will still get the advantage of the data buffering provided by the SSL I/O functions ([SslRead\(\)](#), [SslWrite\(\)](#), *et al.*).

You can use `sslModeSsl` as a mask to determine if SSL is on:

---

```
If (SslContextGet_Mode(ssl) & sslModeSsl)
    /* SSL protocol enabled */
else
    /* Using cleartext */
```

---

### The Mode Attribute in SslContexts

Setting an [SslContext](#)'s Mode (even if you set it to the status quo) causes an "SSL reset." This sets most of the other SSL attributes back to their default values, and puts the [SslContext](#) in the proper state to open a new SSL session. Note that an SSL reset doesn't clear SSL session information, thus allowing the previous session to be used in a new session with the same server. See [ReadStreaming](#) for details.

To force an SSL reset, do this:

---

```
SslContextSet_Mode(context, SslContextGet_Mode(context));
```

---

Switching from SSL-off to SSL-on initiates a new SSL handshake.

`sslModeFlush` is a flag that, when present, clears the internal read and write buffers. Any data in the buffers is lost. You would normally use this flag when you're reusing an SSL session.

## PeerCert

Structure that represents the certificate that was supplied by the server. [SslContext](#) only, read only.

## SSL Attributes and Macros

### *PeerCommonName*

---

type:        ([SslExtendedItems](#) \*)

values:      If a certificate is available, the context passes back a pointer to a structure. See [SslExtendedItems](#) for details.

default:     ([SslExtendedItems](#) \*) NULL

macros:      SslContextGet\_PeerCert

## PeerCommonName

Structure that contains information that you use to retrieve the server's common name from a previously retrieved certificate. [SslContext](#) only, read only.

type:        ([SslExtendedItem](#) \*)

values:      See the example, below.

default:     ([SslExtendedItem](#) \*) NULL

macros:      SslContextGet\_PeerCommonName

To use this attribute, you must also retrieve the server's certificate through [SslContextGet\\_PeerCert](#). You then perform some pointer juggling that's best explained through an example:.

---

```
SslExtendedItems *cert;
SslExtendedItem *commonName;

/* The length of the common name */
Int16 length;

/* A pointer to the beginning of the common name. */
Int8 *bytes;

SslContextGet_PeerCert( ssl, &cert );
if ( cert != NULL ) {
    SslContextGet_PeerCommonName( ssl, &commonName );

    /* Get the common name length from the SslExtendedItem
     * struct.
     */
    length = commonName->len;
```

---

```

/* The name itself is in the peer certificate, located
 * at an offset (into the SslExtendedItems struct) as
 * indicated by the offset field of the SslExtendedItem
 * struct.
 */
bytes = ((Int8 *)cert) + commonName->offset;

/* Now that we have a pointer to the name and the
 * length of the name, we can compare it to the
 * expected value.
 */
StrNCompare ( bytes, expectedValue, length );
}

```

---

If you're using SSL in an https context, for example, the client application should ensure that the common name contained in the server's certificate matches the requested URL.

## ProtocolVersion

The SSL protocol that's being used

type:        Int32

values:      sslVersionSSLv3 only; if you set the protocol to some other value, SSL won't work.

macros:      SslLibSet\_ProtocolVersion  
               SslLibGet\_ProtocolVersion  
               SslContextSet\_ProtocolVersion  
               SslContextGet\_ProtocolVersion

## RbufSize

The size of the internal read buffer, in bytes.

type:        Int32

values:      [0, 16384]

## SSL Attributes and Macros

### *ReadBufPending*

---

default: 2048

macros: SslLibSet\_RbufSize  
SslLibGet\_RbufSize  
SslContextSet\_RbufSize  
SslContextGet\_RbufSize

The actual size of the read buffer may be different from that which you request: The buffer is automatically increased in size if the SSL protocol and/or decryption algorithm demand it. For example, if decryption can only operate on an entire record, and if it's passed a record that's longer than the read buffer size, the buffer will grow to accommodate the record.

The [ReadStreaming](#) attribute describes an advanced use of the read buffer that decreases data reading latency.

### **ReadBufPending**

Returns the number of bytes that are waiting to be read from the context's read buffer. The measurement includes in-coming SSL encryption data. [SslContext](#) only; read only.

type: Int32

values: [0, 16k]

macros: SslContextGet\_ReadBufPending

This attribute is provided for debugging purposes.

### **ReadOutstanding**

Returns the number of bytes that remain to be read from the current SSL record. [SslContext](#) only; read only.

type: Int32

values: [0, 16k]

0 means the entire record has been read and verified.

macros: SslContextGet\_ReadOutstanding

See [ReadStreaming](#) for a justification of this attribute.

## ReadRecPending

Returns the number of “real” bytes of data in the context’s read buffer. The measurement doesn’t include SSL encryption data. [SslContext](#) only; read only.

type: Int32

values: [0, 16k]

macros: SslContextGet\_ReadRecPending

If this attribute is 0, the next [SslRead\(\)](#) or [SslReceive\(\)](#) will cause a [NetLibReceive\(\)](#) invocation.

## ReadStreaming

Allows partial record data to be read.

type: Int32

values: **0:** Always wait for an entire record before reading.

**non-zero:** Don’t wait for an entire record.

default: 0

macros: SslLibSet\_ReadStreaming

SslLibGet\_ReadStreaming

SslContextSet\_ReadStreaming

SslContextGet\_ReadStreaming

If the network is running at a very low rate (such as a 300 baud modem), you may want to allow in-coming data to be returned to

## SSL Attributes and Macros

### *SessionReused*

---

the application before a full record has been downloaded. Notice, however, that “stream reading” has an implication on security: Since you can’t verify the record until it has been fully read, you must be careful what you do with stream read data. You should never respond to in-coming data until an entire record has been read and verified. The [ReadOutstanding](#) attribute can be used to determine if a record has been fully read and verified.

The SSL library may reject stream reading requests. See the [Streaming](#) attribute for details.

To retrieve streaming data, use the [SslPeek\(\)](#) and [SslConsume\(\)](#) functions (rather than [SslRead\(\)](#) or [SslReceive\(\)](#)).

## SessionReused

Indicates whether the context is reusing a previous session. [SslContext](#) only, read only.

type:        Int32

values:     **0:**        No, this is a new session.

**non-zero:** Yes, this session is a continuation of a previous session.

default:    0

macros:     SslContextGet\_SessionReused

SSL can re-establish a previously formed session if both ends of the network connection have a common notion of the session’s parameters (as represented by the [SslSession](#) attribute). Reusing a session lets the SSL protocol use a truncated (faster) handshake.

## Socket

Specifies the net library socket that an [SslContext](#) will use in I/O operations. [SslContext](#) only.

type:       [NetSocketRef](#) (Int16)  
 default:     none  
 macros:      SslContextSet\_Socket  
               SslContextGet\_Socket

An SSL context can't perform any network operations until it's supplied with a valid, open, connected [NetSocketRef](#). The SSL library doesn't perform any Net library operations Creation, initialization, and destruction of the socket that the [NetSocketRef](#) represents is the application's responsibility.

This call is used to specify the net library socket that the [SslContext](#) should use to perform it's network I/O operations. A [SslContext](#) is unable to perform any network operation until the application creates and supplies a suitable [NetSocketRef](#).

---

**IMPORTANT:** The SslLib library uses the [NetSocketRef](#) to send data and receive data only—it doesn't call any other net library functions except for [NetLibSend\(\)](#) and [NetLibReceive\(\)](#). **All socket creation, configuration, and shutdown operations must be performed by the application.**

---

## SslSession

Structure that represents the current or impending SSL session. [SslContext](#) only.

type:        ([SslSession](#) \*)  
 values:      When a session is opened, the context populates the structure with information. See [SslSession](#) for details.  
 macros:      SslContextSet\_SslSession  
               SslContextGet\_SslSession

You can fine-tune an impending session by creating and populating an [SslSession](#) that you pass in through

## SSL Attributes and Macros

### *SslVerify*

---

`SslContextSet_SslSession`. As with most pointer attributes, the structure is copied into the context. The next time you call `SslOpen()`, the embedded `SslSession` information is used to configure the session. The structure is then modified, if necessary, to reflect the actual state of the session.

Session information isn't cleared in an SSL reset. Maintaining the session info allows a session to be reused, as discussed in [SessionReused](#).

## SslVerify

Structure that's used during certificate verification. `SslContext` only, read only.

type: `(SslVerify *)`

values: See the example, below.

default: `(SslVerify *) NULL`

macros: `SslContextGet_SslVerify`

If certification runs into a problem that can't be resolved by the verify callback function (see [VerifyCallback](#)), or if you haven't registered a verify callback function, an error will be returned to your application, which can retrieve the `SslVerify` structure in an attempt to solve the conflict itself.

If your application determines that the error isn't fatal, it should clear the error (through `SslContextSet_Error`) and reinvoke the function that returned the error.

## Streaming

Tells you if the context is stream reading. `SslContext` only; read only.

type: `Int32`

values:     **0:**     The context isn't stream reading.  
             **non-zero:** The context is stream reading.

macros:     SslContextGet\_Streaming

In some cases, the SSL library may decide that it doesn't want to do stream reading, regardless of the value of the [ReadStreaming](#) attribute. The value of this attribute tells you the truth.

## VerifyCallback

Identifies the callback function that's used during certificate verification.

type:       ([SslCallback](#) \*)

default:     none

macros:     SslLibSet\_VerifyCallback  
             SslLibGet\_VerifyCallback  
             SslContextSet\_VerifyCallback  
             SslContextGet\_VerifyCallback

For more information, see the [SslCallbackFunc\(\)](#) description in [Chapter 80, "SSL Functions."](#)

## WbufSize

The size of the internal write buffer, in bytes. Note that SSL protocol overhead takes about 30 bytes, so the "writable" portion of the write buffer will be slightly smaller than the value of `WbufSize`.

type:       Int32

values:     [0, 16384]

## SSL Attributes and Macros

### *WriteBufPending*

---

default: 1024

macros: SslLibSet\_WbufSize  
SslLibGet\_WbufSize  
SslContextSet\_WbufSize  
SslContextGet\_WbufSize

### WriteBufPending

Returns the number of bytes of data in the context's write buffer (i.e. waiting to be sent to the remote endpoint). [SslContext](#) only; read only.

type: Int32

values: [0, 16k]

macros: SslContextGet\_WriteBufPending

This attribute should be zero unless [AutoFlush](#) is disabled. You must explicitly flush (through [SslFlush\(\)](#)) before the value of WriteBufPending reaches the value of [WbufSize](#) (the maximum size of the write buffer).

## SSL Attribute Constants

As explained earlier, each of the attribute macros is a cover for one of the eight attribute-setting or -getting functions. (The functions are described in [Chapter 80, "SSL Functions,"](#) on page 2043.) Instead of invoking the attribute macros, you can call the attribute functions, instead.

Unlike the macros, the functions don't correspond to specific attributes. To tell the function which attribute you want it to access, you pass in one of the attribute constants. These constants usually take the form

sslAttrLibAttribute

or

`sslAttrAttribute`

where the former represents the attribute in an [SslLib](#) object, and the latter is the [SslContext](#) version (note the lack of a qualifying “Context” in the names of the [SslContext](#) macro constants). As examples:

- `sslAttrLibMode` represents the [Mode](#) attribute in an [SslLib](#) object.
- `SslAttrMode` is the [Mode](#) attribute in an [SslContext](#).
- `sslAttrLibAutoFlush` and `sslAttrAutoFlush` signify the [AutoFlush](#) attribute in the [SslLib](#) and [SslContext](#).

Note that there are a few exceptions to this formula.

Alphabetical lists of the attribute constants are given below, one list for [SslLib](#) attributes, and a second for [SslContext](#). The constant names that don’t conform to the formula, above, are noted.

#### SslLib Attribute Constants

`sslAttrLibAppInt`  
`sslAttrLibAppPtr`  
`sslAttrLibAutoFlush`  
`sslAttrLibBufferedReuse`  
`sslAttrLibCompat`  
`sslAttrLibDontSendShutdown`  
`sslAttrLibDontWaitForShutdown`  
`sslAttrLibInfoCallback`  
`sslAttrLibInfoInterest`  
`sslAttrLibMode`  
`sslAttrLibProtocolVersion`  
`sslAttrLibRbufSize`  
`sslAttrLibReadStream`  
`sslAttrLibSessionCallback`  
`sslAttrLibVerifyCallback`  
`sslAttrLibWbufSize`

#### SslContext Attribute Constants

`sslAttrAppInt`  
`sslAttrAppPtr`  
`sslAttrAutoFlush`  
`sslAttrBufferedReuse`  
  
→ `sslAttrCertPeerCert` [PeerCert](#)

## SSL Attributes and Macros

### SSL Attribute Constants

---

→ `sslAttrCertPeerCommonName` [PeerCommonName](#)  
→ `sslAttrCertSslVerify` [SslVerify](#)  
`sslAttrCompat`  
→ `sslAttrCspCipherSuiteInfo` [CipherSuiteInfo](#)  
→ `sslAttrCspCipherSuites` [CipherSuites](#)  
→ `sslAttrCspCipherSuites` [CipherSuite](#)  
→ `sslAttrCspSslSession` [SslSession](#)  
`sslAttrDontSendShutdown`  
`sslAttrDontWaitForShutdown`  
`sslAttrError`  
`sslAttrHsState`  
`sslAttrInfoCallback`  
`sslAttrInfoInterest`  
`sslAttrIoFlags`  
→ `sslAttrIoSocket` [Socket](#)  
`sslAttrIoStruct`  
`sslAttrIoTimeout`  
`sslAttrLastAlert`  
`sslAttrLastApi`  
`sslAttrLastIo`  
`sslAttrMode`  
`sslAttrProtocolVersion`  
`sslAttrRbufSize`  
`sslAttrReadBufPending`  
`sslAttrReadOutstanding`  
`sslAttrReadRecPending`  
`sslAttrReadStreaming`  
`sslAttrSessionReused`  
`sslAttrStreaming`  
`sslAttrVerifyCallback`  
`sslAttrWbufSize`  
`sslAttrWriteBufPending`

# SSL Error Codes

---

The SSL functions described in [Chapter 80, “SSL Functions,”](#) return `errNone` if successful, and non-zero otherwise. The table below lists and explains these “non-zero” values.

In addition to the errors listed below, the SSL functions also pass back errors that are returned by the underlying network library (NetLib) functions.

---

**WARNING!** The `sslErrOk` error code, declared in `SslLib.h` does *not* indicate success. The error-returning SSL functions return `errNone` for success.

---

The errors are grouped under topical headings, and listed alphabetically therein. The groups are:

- [SSL Function Protocol Errors](#) indicate a malformed function call, or other non-SSL dilemma.
- [SSL Alerts](#) are errors that your application may need to explore to find out what really happened.
- [SSL Handshake Errors](#) are returned while SSL handshake messages are being passed between the client and the server.
- [SSL Cryptography Errors](#) indicate that a cryptographic operation has failed.
- [SSL Illegal Message Errors](#) are returned when SSL receives an unexpected message type.
- [SSL Certificate Errors](#) describe the different failures during certificate verification.

## SSL Error Codes

### *SSL Function Protocol Errors*

---

## SSL Function Protocol Errors

`sslErrBadArgument`

A function argument was (generally) invalid.

`sslErrBadLength`

A buffer length argument to a data-reading or -writing function was invalid.

`sslErrBadOption`

This means the same as `sslErrBadArgument`.

`sslErrBufferTooSmall`

A buffer supplied to this function wasn't big enough for the data that the functions wanted to stuff into it.

`sslErrEof`

You attempted to read or write a socket that isn't open.

`sslErrFailed`

General, unspecified error.

`sslErrNullArg`

You passed in a NULL argument. This is returned, for example, if you pass in a NULL pointer where a valid [SslLib](#) or [SslContext](#) is expected.

`sslErrOutOfMemory`

Not enough memory to allocate the resources that are needed by this function.

## SSL Alerts

`sslErrCbAbort`

Returned by a callback function to indicate that the caller should exit. See [SslCallbackFunc\(\)](#) in [Chapter 80, "SSL Functions."](#)

`sslErrIo`

Indicates that an underlying NetLib function has returned a non-fatal error, such as a timeout. When you get this error, you should try to determine what the exact error is—you usually start by looking at the context's [Compat](#) attribute. After you clear the error, you can try to call the function again.

`sslErrFatalAlert`

An SSL fatal alert was received. To handle the alert, see the [LastAlert](#) attribute in [Chapter 82](#), “[SSL Attributes and Macros](#).”

## SSL Handshake Errors

`sslErrBadPeerFinished`

The final check of the SSL handshake failed. This means that there was a problem establishing a shared secret value. It could be caused by the server using a certificate that does not match its private key.

`sslErrExtraHandshakeData`

An SSL handshake message contained data that shouldn't have been there.

`sslErrHandshakeEncoding`

An error occurred while an SSL handshake message (from the server) was being decoded.

`sslErrHandshakeProtocol`

An error occurred while processing a decoded SSL handshake message.

`sslErrReadAppData`

A handshake message was expected, but application data was read.

## SSL Cryptography Errors

`sslErrCsp`

General cryptography error.

`sslErrDivByZero`

Math error. This can happen if a certificate has an invalid public key.

`sslErrNoModInverse`

Another math error. See above.

`sslErrNoRandom`

There was a problem with the random number source.

## SSL Error Codes

### *SSL Illegal Message Errors*

---

## SSL Illegal Message Errors

`sslErrBadSignature`

An invalid signature was found on an ephemeral Cipher Suite message.

`sslErrWrongMessage`

An invalid or inappropriate SSL message was received.

`sslErrUnexpectedRecord`

The wrong type of record was received.

`sslErrRecordError`

An invalid record was received by the [SslContext](#).

## SSL Certificate Errors

`sslErrBadDecode`

Something went wrong while decoding values during certificate verification.

`sslErrCert`

General certificate error.

`sslErrCertDecodeError`

The server's certificate could not be decoded.

`sslErrUnsupportedCertType`

The server sent a certificate that isn't supported (it contains a public key that can't be decoded).

`sslErrUnsupportedSignatureType`

The server sent a certificate that has an unrecognized signature type.

`sslErrVerifyBadSignature`

The certificate's signature is invalid

`sslErrVerifyConstraintViolation`

The certificate violates an X509 extension.

`sslErrVerifyNotAfter`

The certificate has expired.

`sslErrVerifyNotBefore`

The certificate is too early (the timestamp window is in the future).

`sslErrVerifyNoTrustedRoot`

A trusted certificate store (necessary for certificate verification) couldn't be found.

`sslErrVerifyUnknownCriticalExtension`

An X509 extension (that's marked as "critical") isn't understood by the certificate verification routines.

## SSL Error Codes

*SSL Certificate Errors*

---

# SMS Exchange Library

---

This chapter describes the SMS Exchange Library API declared in the header file `SmsLib.h`. It discusses the following topics:

- [SMS Exchange Library Data Structures](#)
- [SMS Exchange Library Constants](#)

You interact with the SMS Exchange Library using the Exchange Manager APIs described in [Chapter 57, “Exchange Manager,”](#) on page 1245 of this book. For further information on using Exchange Manager, see “[Object Exchange](#)” on page 1 of the of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## SMS Exchange Library Data Structures

### SmsParamsType Struct

**Purpose** The `SmsParamsType` structure identifies information specific to the SMS Exchange Library. The `socketRef` field of the [ExgSocketType](#) structure is set to this structure when you send or receive data using the SMS Exchange Library. You only need to create this structure and assign it to the `socketRef` field if you have an SMS message to send and want to use non-default values for some of the fields; otherwise, the SMS Exchange Library creates this structure for you and provides default values.

**Prototype**

```
typedef struct SmsParamsTag
{
    UInt32 creator;
    UInt16 smsID;
    Char *extension;
    Char *mimeTypes;
```

## SMS Exchange Library

### *SmsParamsType*

---

```
    UInt32 appCreator;
    UInt8 dataCodingScheme;
    UInt8 networkType;
    UInt8 dataType;
    UInt16 nbsDestPort;
    UInt16 nbsSrcPort;
    union
    {
        SmsSendParamsType send;
        SmsReceiveParamsType receive;
        SmsReportParamsType report;
    } data;
} SmsParamsType, *SmsParamsPtr;
```

#### Field Descriptions

|           |                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| creator   | Creator ID of the SMS Exchange Library. Always set this to sysFileCSmsLib.                                                                                                                                                   |
| smsID     | The ID of the message that was sent. Do not set this field directly; the SMS Exchange Library should set it.                                                                                                                 |
| extension | If the SMS message has an attachment, this field specifies the attachment name. Do not set this field directly; the SMS Exchange Library sets it if necessary. See the appCreator field description for details.             |
| mimeTypes | If the SMS message has an attachment, this field specifies the MIME type of the attachment. Do not set this field directly; the SMS Exchange Library sets it if necessary. See the appCreator field description for details. |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| appCreator       | <p>The creator ID of the target application for the attachment to the SMS message. Do not set this field directly; the SMS Exchange Library sets it if necessary.</p> <p>When the SMS Exchange Library receives a message with an attachment, it unwraps the message and attempts to deliver the attachment directly to an application that is registered to receive it. If no application is registered to receive unwrapped attachments of that type, the SMS Exchange Library sends the entire SMS message, and it sets the extension, mimeType, and appCreator fields in this structure. The SMS application can use this information to have the Exchange Manager deliver the attachment to the appropriate application using the Local Exchange Library.</p> |
| dataCodingScheme | <p>The data encoding scheme that the message uses. See <a href="#">SMS Data Coding Scheme Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| networkType      | <p>Indicates the type of advanced parameters. See <a href="#">SMS Network Type Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| dataType         | <p>Identifies the type of message being received, such as multipart or return receipt. See <a href="#">SMS Message Type Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| nbsDestPort      | <p>The Narrow Band Socket (NBS) port on which you want the data sent. The SMS Exchange Library sets this for you if you leave it blank. When data is being received, this field is set to the NBS port on which the data was received.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## SMS Exchange Library

### *SmsPrefType*

---

|            |                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nbsSrcPort | The NBS port on which you want the data sent. You should set this field to the same value as nbsDestPort. If you leave it blank, the SMS Exchange Library provides a value for you. |
| data       | The data being sent or received. See <a href="#">SmsReceiveParamsType</a> , <a href="#">SmsReportParamsType</a> , and <a href="#">SMSSendParamsType</a> .                           |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### SmsPrefType Struct

**Purpose** The SmsPrefType structure defines the SMS Exchange Library preferences for sending and receiving SMS messages. Applications can use the [ExgControl\(\)](#) function to get, set, or display these preferences to the user.

**Prototype**

```
typedef struct SmsPrefTag
{
    UInt32 validity;
    UInt16 warnOver;
    Boolean leave;
    Boolean report;
    Boolean autoSMSC;
    Char smscNumber[kSmsMaxPhoneSize];
} SmsPrefType, *SmsPrefPtr;
```

### Field Descriptions

|            |                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| validity   | The number of seconds before the message expires. If the message cannot be delivered to the recipient, the service center repeatedly attempts to deliver the message until it expires. The default is one hour.                                                                                                                  |
| warnOver   | The number of parts a user can send without confirmation. If the user attempts to send a message with more than this number of parts, an alert is displayed, and the user can choose to send the message anyway. The default is 3 parts. (If the user attempts to send a message with more than 3 parts, an alert is displayed.) |
| leave      | If <code>true</code> , any incoming messages retrieved from a phone remain on the phone as well. If <code>false</code> , the messages are deleted from the phone's inbox.                                                                                                                                                        |
| report     | If <code>true</code> , the user receives confirmation that an SMS message was delivered.                                                                                                                                                                                                                                         |
| autoSMSC   | If <code>true</code> , don't use the value stored in the <code>smscNumber</code> field.                                                                                                                                                                                                                                          |
| smscNumber | The message center to be used. If <code>NULL</code> or the empty string, the SMS message center set by the phone is used.                                                                                                                                                                                                        |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### SmsReceiveCDMAParamsType Struct

**Purpose** The [SmsReceiveParamsType](#) includes an `SmsReceiveCDMAParamsType` structure for CDMA messages.

**Prototype**

```
typedef struct SmsReceiveCDMAParamsTag
{
    UInt8 messageType;
    TelSmsDateTimeType validityPeriod;
    UInt8 priority;
    UInt8    privacy;
```

## SMS Exchange Library

### *SmsReceiveCDMAParamsType*

---

```
Boolean alertOnDeliveryRequest;  
Boolean manualAckRequest;  
UInt8    voiceMessageNumber;  
UInt8    languageIndicator;  
Char *    callbackNumberAddress;  
} SmsReceiveCDMAParamsType,  
*SmsReceiveCDMAParamsPtr;
```

#### Field Descriptions

|                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| messageType            | The type of the message. This is one of the <a href="#">SMS Message Type Constants</a> defined in <code>TelephonyMgr.h</code> .                  |
| validityPeriod         | The amount of time for which the message is valid. See <a href="#">TelSmsDateTimeType</a> . The default is set according to the SMS preferences. |
| priority               | The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> defined in <code>TelephonyMgr.h</code> .             |
| privacy                | The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> defined in <code>TelephonyMgr.h</code> .  |
| alertOnDeliveryRequest | true if the user is to be alerted upon delivery of this message, and false if not.                                                               |
| manualAckRequest       | true if a confirmation is requested from the recipient, and false if not.                                                                        |
| voiceMessageNumber     | The number of new messages in your voice mail.                                                                                                   |

|                       |                                                            |
|-----------------------|------------------------------------------------------------|
| languageIndicator     | Reserved for future use.                                   |
| callbackNumberAddress | The callback number to which confirmations are to be sent. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsReceiveGSMPParamsType Struct

**Purpose** The [SmsReceiveParamsType](#) includes an SmsReceiveGSMPParamsType structure for GSM messages.

**Prototype**

```
typedef struct SmsReceiveGSMPParamsTag
{
    UInt16 protocolId;
    Char *serviceCenterNumber;
    Boolean replyPath;
} SmsReceiveGSMPParamsType,
*SmsReceiveGSMPParamsPtr;
```

### Field Descriptions

|                     |                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------|
| protocolId          | Reserved for future use.                                                                                                    |
| serviceCenterNumber | The SMS service center that must be used to send a reply. If NULL, the service center specified in the preferences is used. |
| replyPath           | If true, replies must be made through the SMS service center specified by serviceCenterNumber.                              |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsReceiveParamsType Struct

**Purpose** The SmsReceiveParamsType structure is used as the data field for the [SmsParamsType](#) structure when the SMS Exchange Library has received data. The SMS Exchange Library always supplies the values for these fields.

## SMS Exchange Library

### *SmsReceiveParamsType*

---

**Prototype**

```
typedef struct SmsReceiveParamsTag
{
    UInt32 timeStamp;
    Char *originatingAddress;
    UInt8 leaveOnPhone:1;
    UInt8 forceSlotMode:1;
    UInt8 reserved:6;
    UInt16 index;
    Boolean otherToReceive;
    Boolean reportDeliveryIndicator;
    union
    {
        SmsReceiveGSMParamsType gsm;
        SmsReceiveCDMAParamsType cdma;
        SmsReceiveTDMAParamsType tdma;
    } protocol;
} SmsReceiveParamsType, *SmsReceiveParamsPtr;
```

#### Field Descriptions

|                    |                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeStamp          | The time at which the message was delivered, given as the number of seconds since January 1, 1904.                                                               |
| originatingAddress | The number from which the message was received.                                                                                                                  |
| leaveOnPhone       | If <code>true</code> , messages received on the phone are not deleted from the phone's inbox. If not specified, this is set according to the system preferences. |
| forceSlotMode      | If <code>true</code> , use slot mode parsing. If <code>false</code> , use block mode parsing. The default is block mode.                                         |
| reserved           | Reserved for future use.                                                                                                                                         |
| index              | Location where the message is stored on the mobile phone.                                                                                                        |

|                      |                                                                                   |                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
|                      | otherToReceive                                                                    | If true, there are more messages to be received from the service center.                                                                  |
|                      | reportDeliveryIndicator                                                           | If true, the sender has requested confirmation. The recipient of the message does not send the confirmation; the SMS service center does. |
|                      | protocol                                                                          | Values specific to the protocol used to send the message. Currently, only GSM is supported.                                               |
| <b>Compatibility</b> | This structure is only defined if <a href="#">4.0 New Feature Set</a> is present. |                                                                                                                                           |

## SmsReceiveTDMAParamsType Typedef

|                      |                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | The <a href="#">SmsReceiveParamsType</a> includes an SmsReceiveTDMAParamsType structure for TDMA messages. This structure is currently the same as the <a href="#">SmsReceiveCDMAParamsType</a> structure. |
| <b>Prototype</b>     | <pre>typedef SmsReceiveCDMAParamsType     SmsReceiveTDMAParamsType,     *SmsReceiveTDMAParamsPtr;</pre>                                                                                                    |
| <b>Compatibility</b> | This structure is only defined if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                          |

## SmsReportParamsType Struct

|                  |                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>   | The SmsReportParamsType structure is used as the data field for the <a href="#">SmsParamsType</a> structure when the SMS Exchange Library has received a delivery confirmation. The SMS Exchange Library always sets the values for these fields. |
| <b>Prototype</b> | <pre>typedef struct SmsReportParamsTag {     UInt32 timeStamp;     UInt16 index;     UInt8 reportType;</pre>                                                                                                                                      |

## SMS Exchange Library

### *SmsSendCDMAParamsType*

---

```
    UInt8 report;  
    Char* originatingAddress;  
} SmsReportParamsType, *SmsReportParamsPtr;
```

#### Field Descriptions

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| timeStamp          | The date and time at which the message was delivered, given as the number of seconds since January 1, 1904. |
| index              | Location where the message is stored on the mobile phone.                                                   |
| reportType         | One of the Delivery Report Type constants defined in <code>TelephonyMgr.h</code> .                          |
| report             | One of the Delivery Status Report constants defined in <code>TelephonyMgr.h</code> .                        |
| originatingAddress | Phone number to which the message was sent.                                                                 |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsSendCDMAParamsType Struct

**Purpose** The [SMSSendParamsType](#) includes an `SmsSendCDMAParamsType` structure for CDMA messages.

**Prototype**

```
typedef struct SmsSendCDMAParamsTag  
{  
    UInt8    messageType;  
    TelSmsDateTimeType deferredDate;  
    UInt8    priority;  
    UInt8    privacy;  
    UInt8    alertOnDelivery:1;  
    UInt8    manualAckRequest:1;  
    UInt8    reserved:6;  
    Char*    callbackNumber;  
} SmsSendCDMAParamsType, *SmsSendCDMAParamsPtr;
```

### Field Descriptions

|                  |                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| messageType      | The type of the message. This is one of the <a href="#">SMS Message Type Constants</a> constants defined in TelephonyMgr.h. |
| deferredDate     | Not used.                                                                                                                   |
| priority         | The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .                               |
| privacy          | The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .                    |
| alertOnDelivery  | true if the user is to be alerted upon delivery of this message, and false if not.                                          |
| manualAckRequest | true if a confirmation is requested from the recipient, and false if not.                                                   |
| reserved         | Reserved for future use.                                                                                                    |
| callbackNumber   | Number to which the confirmation should be sent.                                                                            |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### SmsSendGSMParamsType Struct

**Purpose** The [SMSSendParamsType](#) includes an SmsSendGSMParamsType structure for GSM messages.

**Prototype**

```
typedef struct SmsSendGSMParamsTag
{
    UInt16 protocolId;
    Char *serviceCenterNumber;
    Boolean rejectDuplicated;
    Boolean replyPath;
} SmsSendGSMParamsType, *SmsSendGSMParamsPtr;
```

#### Field Descriptions

|                                  |                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>protocolId</code>          | Reserved for future use.                                                                                                                                                                        |
| <code>serviceCenterNumber</code> | The message center to be used. If not specified, the service center is set according to the system preferences.                                                                                 |
| <code>rejectDuplicated</code>    | If <code>true</code> , the service center rejects messages that have the same message ID, destination address, and originating address as a previously submitted message.                       |
| <code>replyPath</code>           | If <code>true</code> , the service center that delivers the message is requested to provide information about itself to the recipient so that replies are made through the same service center. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

#### SMSSendParamsType Struct

**Purpose** The `SMSSendParamsType` structure is used as the data field for the [SmsParamsType](#) structure when the SMS Exchange Library is sending data.

**Prototype**

```
typedef struct SmsSendParamsTag
{
    TelSmsDateTimeType validityPeriod;
    Char *destinationAddress;
    UInt8 networkDeliveryRequested:1;
    UInt8 ignoreDefaultValue:1;
    UInt8 reserved:6;
    UInt16 partCount;
    UInt16 lastPart;
    UInt8 converter;
    union
    {
        SmsSendGSMPParamsType gsm;
```

```

        SmsSendCDMAParamsType cdma;
        SmsSendTDMAParamsType tdma;
    } protocol;
} SmsSendParamsType, *SmsSendParamsPtr;

```

### Field Descriptions

|                          |                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| validityPeriod           | The amount of time for which the message is valid. See <a href="#">TelSmsDateTimeType</a> . The default is set according to the SMS preferences.                                                                              |
| destinationAddress       | A buffer that contains the phone number of the message recipient. If no phone number is supplied, the user is prompted for the phone number.                                                                                  |
| networkDeliveryRequested | If true, the SMS service center sends a delivery confirmation. The default is set according to the SMS preferences. The SMS Exchange Library disables this field for multipart messages.                                      |
| ignoreDefaultValue       | If false, the validity period, network delivery requested, and SMS center specified in the preferences are used regardless of the values supplied in this structure. If true, the values supplied in this structure are used. |
| reserved                 | Reserved for future use.                                                                                                                                                                                                      |
| partCount                | The number of parts in the message. 0 means that the message is not a multipart message. If NBS is used to send the message, it determines the number of parts.                                                               |

## SMS Exchange Library

### *SmsSendTDMAParamsType*

|                        |                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| <code>lastPart</code>  | The last part of a multipart message that was successfully sent.                          |
| <code>converter</code> | The header added to the data to specify how it is converted.                              |
| <code>protocol</code>  | Data specific to the protocol used to send the message. Currently, only GSM is supported. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### **SmsSendTDMAParamsType Typedef**

**Purpose** The [SMSSendParamsType](#) includes an `SmsSendTDMAParamsType` structure for TDMA messages. This structure is currently the same as the [SmsSendCDMAParamsType](#) structure.

**Prototype**

```
typedef SmsSendCDMAParamsType  
        SmsSendTDMAParamsType, *SmsSendTDMAParamsPtr;
```

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SMS Exchange Library Constants

### **SMS Control Constants**

The SMS control constants are passed as the operation parameter to the [ExgControl\(\)](#) function. The `ExgControl` function is a way to communicate directly with the SMS Exchange Library. The following table lists the operation constant, the type of data that should be passed as the `valueP` parameter to [ExgControl\(\)](#), and what the SMS Exchange Library does in response.

**Table 84.1 ExgControl operations for SMS library**

| Operation                     | value Data Type                                | Description                                                                                                                                                                                                                                                                                       |
|-------------------------------|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgLibSmsPrefGetOp            | <a href="#">SmsPrefType</a>                    | Returns a pointer to the SMS Exchange Libraries preferences in valueP, creating the preferences and setting them to the default values if they do not exist.                                                                                                                                      |
| exgLibSmsPrefGetDefaultOp     | <a href="#">SmsPrefType</a>                    | Returns the default values for the SMS Exchange Library preferences.                                                                                                                                                                                                                              |
| exgLibSmsPrefSetOp            | <a href="#">SmsPrefType</a>                    | Sets the SMS Exchange Library preferences to the values passed in valueP.                                                                                                                                                                                                                         |
| exgLibSmsPrefDisplayOp        | kSmsNetworkAuto or kSmsNetworkGSM. Input only. | Display a form that allows the user to set the SMS preferences.                                                                                                                                                                                                                                   |
| exgLibSmsIncompleteGetCountOp | UInt16. Output only.                           | Get the number of incomplete messages currently stored in the SMS Exchange Library. The library stores message parts as it receives them. When it has received all of the parts, it reassembles the message and delivers it. This operation tells how many messages are currently under assembly. |
| exgLibSmsIncompleteDeleteOp   | UInt16. Input only.                            | Delete the incomplete message with the ID passed in valueP. Pass -1 to delete all incomplete messages.                                                                                                                                                                                            |

**Compatibility**    These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Data Coding Scheme Constants

The SMS data coding scheme constants describe the coding scheme used for SMS data. These values are used as the `dataCodingScheme` parameter of the [SmsParamsType](#) structure.

| Constant                         | Value | Description                                 |
|----------------------------------|-------|---------------------------------------------|
| <code>kSmsRowDataEncoding</code> | 0     | 8-bit encoding scheme. This is the default. |
| <code>kSmsTextEncoding</code>    | 1     | 7-bit encoding scheme.                      |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Network Type Constants

The SMS network type constants identify the type of network being used for SMS messages. Currently, only the GSM network is supported.

| Constant                     | Value                    | Description                                           |
|------------------------------|--------------------------|-------------------------------------------------------|
| <code>kSmsNetworkAuto</code> | -1                       | The network is set by the phone. This is the default. |
| <code>kSmsNetworkCDMA</code> | <code>kTelNwkCDMA</code> | A CDMA network. Currently not supported.              |
| <code>kSmsNetworkGSM</code>  | <code>kTelNwkGSM</code>  | A GSM network.                                        |
| <code>kSmsNetworkTDMA</code> | <code>kTelNwkTDMA</code> | A TDMA network. Currently not supported.              |
| <code>kSmsNetworkPDC</code>  | <code>kTelNwkPDC</code>  | A PDC network. Currently not supported.               |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Message Type Constants

The SMS message type constants identify the type of message being sent. They are used as the `dataType` field of the [SmsParamsType](#) structure.

| Constant           | Value | Description                                                           |
|--------------------|-------|-----------------------------------------------------------------------|
| kSmsMessageType    | 0     | Standard SMS message of no more than 160 bytes. This is the default.  |
| kSmsIncompleteType | 1     | A part of a multipart SMS message.                                    |
| kSmsReportType     | 2     | A confirmation, indicating that an SMS message was successfully sent. |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Converter Constants

The SMS converter constants identify the header information added to an SMS message.

| Constant          | Value | Description                                                 |
|-------------------|-------|-------------------------------------------------------------|
| kSmsNBSCConverter | 0     | An NBS header is added to the message. This is the default. |
| kSmsNoConverter   | 1     | No header is added to the message.                          |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## **SMS Exchange Library**

### *SMS Converter Constants*

---

# Personal Data Interchange Library

---

This chapter provides reference material for the Personal Data Interchange (PDI) library, which provides tools for reading and writing vObjects, including vCards and vCals. This chapter discusses the following topics:

- [PDI Library Data Structures](#)
- [PDI Library Constants](#)
- [PDI Library Functions](#)

The header file `PdiLib.h` declares the Personal Data Interchange library API. The header file `PdiConst.h` declares the constants that you use with the PDI library.

For information about how to use the functions and constants described in this chapter, see [Chapter 3, “Personal Data Interchange,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## PDI Library Data Structures

This section describes the data structures used with the PDI library functions.

### PdiDictionary Typedef

**Purpose** The `PdiDictionary` type is a simple typedef that represents an internal, binary object.

**Prototype**    `typedef UInt8 PdiDictionary;`

## PdiReaderType Struct

**Purpose**    The PdiReaderType data structure represents a PDI reader object, which you use to read data from an input stream.

**Prototype**    `typedef struct _PdiReader {  
    Err                    error;  
    UInt8                encoding;  
    CharEncodingType    charset;  
    UInt16                written;  
    UInt8                fieldNum;  
    UInt16                property;  
    UInt16                propertyValueType;  
    UInt16                parameter;  
    UInt32    parameterPairs[kPDI_ENTRIES_NUMBER];  
    UInt16                customFieldNumber;  
    void                *appData;  
    UInt16                pdiRefNum;  
    UInt16                events;  
    Char                *groupName;  
    Char                *propertyName;  
    Char                *parameterName;  
    Char                *parameterValue;  
    Char                *propertyValue;  
    PdiDictionary        *dictionary[2];  
} PdiReaderType`

## Field Descriptions

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <code>error</code>    | The most recent error.                                                   |
| <code>encoding</code> | The type of encoding for the property value.                             |
| <code>charset</code>  | The character set of the property value.                                 |
| <code>written</code>  | The number of characters that have currently been written to the buffer. |
| <code>fieldNum</code> | The current field number.                                                |

|                                |                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>property</code>          | The ID of the current property.                                                                              |
| <code>propertyValueType</code> | The value type of the current property value.                                                                |
| <code>parameter</code>         | The ID of the most recently parsed parameter name.                                                           |
| <code>parameterPairs</code>    | An integer array with bits set for each parameter value that has been parsed for the current property value. |

---

**NOTE:** You must use the `PdiParameterPairTest` macro to access this field.

---

|                                |                                                                                                                                                                                          |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>customFieldNumber</code> | The number of the custom field parsed by the reader for the current property. Custom fields are used in the Palm <sup>™</sup> Address Book.                                              |
| <code>appData</code>           | Application-dependent data field.                                                                                                                                                        |
| <code>pdiRefNum</code>         | The library reference number associated with this reader.                                                                                                                                |
| <code>events</code>            | The mask of events handled by the reader in its most recent operation. This is a combination of some number of the event constants described in <a href="#">Reader Event Constants</a> . |
| <code>groupName</code>         | The group name for the current property.                                                                                                                                                 |
| <code>propertyName</code>      | The name of the current property.                                                                                                                                                        |
| <code>parameterName</code>     | The name of the current parameter.                                                                                                                                                       |
| <code>parameterValue</code>    | The value of the current parameter.                                                                                                                                                      |

|               |                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| propertyValue | The current property value string.                                                                                                                                                                                                                                           |
| dictionary    | An array of two dictionary pointers. The dictionary[0] entry is the main dictionary built into the PDI library, and the dictionary[1] entry is an optional, custom dictionary associated with the reader object with a call to <a href="#">PdiDefineReaderDictionary()</a> . |

### PdiWriterType Struct

**Purpose** The PdiWriterType data structure represents a PDI writer object, which you use to write data to an output stream.

**Prototype**

```
typedef struct _PdiWriter {  
    void                *appData;  
    UInt16              pdiRefNum;  
    UInt16              encoding;  
    CharEncodingType    charset;  
    Err                 error;  
    PdiDictionary       *dictionary[2];  
} PdiWriterType
```

### Field Descriptions

|           |                                                           |
|-----------|-----------------------------------------------------------|
| appData   | Application-dependent data field.                         |
| pdiRefNum | The library reference number associated with this reader. |
| encoding  | The type of encoding for the property value.              |
| charset   | The character set of the property value.                  |

|            |                                                                                                                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| error      | The most recent error.                                                                                                                                                                                                                                                       |
| dictionary | An array of two dictionary pointers. The dictionary[0] entry is the main dictionary built into the PDI library, and the dictionary[1] entry is an optional, custom dictionary associated with the reader object with a call to <a href="#">PdiDefineReaderDictionary()</a> . |

## PDI Library Constants

This section describes the constants used in the PDI library, which include the following constant types:

- [Buffer Management Constants](#)
- [Encoding Type Constants](#)
- [Error Code Constants](#)
- [Parameter Name Constants](#)
- [Parameter Value Constants](#)
- [Property Name Constants](#)
- [Property Type Constants](#)
- [Property Value Field Constants](#)
- [Property Value Format Constants](#)
- [Reader and Writer Options Constants](#)
- [Reader Event Constants](#)
- [Value Type Constants](#)

## Buffer Management Constants

You use the buffer management constants to determine how buffers are managed in the PDI reader.

## Personal Data Interchange Library

### Encoding Type Constants

---

| Constant                   | Value  | Description                                                                                                                                                                                                                    |
|----------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiResizableBuffer        | 0xFFFF | Indicates that the buffer can be automatically resized by the PDI library.                                                                                                                                                     |
| kPdiDefaultBufferMaxSize   | 0x3FFF | The default maximum buffer size, in bytes. You can change the maximum size of a reader's buffer by calling the <a href="#">PdiDefineResizing()</a> function.                                                                   |
| kPdiDefaultBufferDeltaSize | 0x0010 | The default number of bytes by which the input buffer is grown when the PDI library performs automatic resizing. You can change the delta amount of a reader's buffer by calling <a href="#">PdiDefineResizing()</a> function. |

---

## Encoding Type Constants

You use the encoding type constants to specify the type of encoding used in a vObject reader or writer.

| Constant          | Value                             | Description                                                              |
|-------------------|-----------------------------------|--------------------------------------------------------------------------|
| kPdiASCIIEncoding | 0                                 | The vObject is not encoded.                                              |
| kPdiQPEncoding    | kPdiPAV_ENCODING_QUOTED_PRINTABLE | The vObject uses the quoted printable encoding.                          |
| kPdiB64Encoding   | kPdiPAV_ENCODING_BASE64           | The vObject uses Base 64 encoding. The writer outputs "ENCODING=BASE64." |

| <b>Constant</b>    | <b>Value</b>       | <b>Description</b>                                                                                                                 |
|--------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| kPdiBEncoding      | kPdiPAV_ENCODING_B | The vObject uses Base 64 encoding. This is the same as the kPdiB64Encoding value, except that the PDI writer outputs "ENCODING=B." |
|                    |                    | This encoding is used with the vCard 3.0 standard.                                                                                 |
| kPdiEscapeEncoding | 0x8000             | The vObject uses escapes for special characters.                                                                                   |
| kPdiNoEncoding     | 0x8001             | The PDI writer does not encode the vObject value.                                                                                  |

## Error Code Constants

The PDI library functions return the error code constants shown in the following table to indicate their status.

| <b>Constant</b>       | <b>Description</b>                                                                  |
|-----------------------|-------------------------------------------------------------------------------------|
| pdiErrRead            | An error occurred while reading from the input stream.                              |
| pdiErrWrite           | An error occurred while writing to the output stream.                               |
| pdiErrNoPropertyName  | An attempt was made to write a property value before the property name was written. |
| pdiErrNoPropertyValue | The application did not write the last property value.                              |
| pdiErrMoreChars       | The buffer is full. Superfluous characters have been discarded.                     |

## Personal Data Interchange Library

### Parameter Name Constants

---

| Constant                        | Description                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------|
| <code>pdiErrNoMoreFields</code> | There are no more property fields to read.                                                       |
| <code>pdiErrOpenFailed</code>   | The PDI library could not be opened.                                                             |
| <code>pdiErrCloseFailed</code>  | The PDI library could not be closed. This can occur if another application is using the library. |

## Parameter Name Constants

The `PdiConst.h` file defines several parameter name constants that you can use to specify the name of a parameter in functions that use parameter names. The parameter name constants have the following format:

`kPdiPAN_parameterName`

where *parameterValue* is replaced by a parameter name.

The following table shows examples of parameter name constants. For a complete list, see the `PdiConst.h` file.

| Constant                      | Description             |
|-------------------------------|-------------------------|
| <code>kPdiPAN_TYPE</code>     | The TYPE parameter.     |
| <code>kPdiPAN_ENCODING</code> | The ENCODING parameter. |
| <code>kPdiPAN_STATUS</code>   | The STATUS parameter.   |

## Parameter Value Constants

The `PdiConst.h` file defines several parameter value constants that you can use to specify the name and value of a parameter in functions that use name and value pairs. The parameter value constants have the following format:

`kPdiPAV_parameterName_parameterValue`

where *parameterName* is replaced by a parameter name and *parameterValue* is replaced by a parameter value.

The following table shows examples of parameter value constants. For a complete list, see the `PdiConst.h` file.

| Constant                             | Description                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------|
| <code>kPdiPAV_TYPE_TEL</code>        | The parameter name is <code>TYPE</code> and the parameter value is <code>TEL</code> .        |
| <code>kPdiPAV_ENCODING_BASE64</code> | The parameter name is <code>ENCODING</code> and parameter value is <code>BASE64</code> .     |
| <code>kPdiPAV_ENCODING_8BIT</code>   | The parameter name is <code>ENCODING</code> and the parameter value is <code>8BIT</code> .   |
| <code>kPdiPAV_STATUS_ACCEPTED</code> | The parameter name is <code>STATUS</code> and the parameter value is <code>ACCEPTED</code> . |

## Property Name Constants

The `PdiConst.h` file defines several property name constants that you can use to specify the name of a PDI property in functions that use property names. The property name constants have the following format:

`kPdiPRN_propertyName`

where *propertyName* is replaced by a property name.

The following table shows examples of property name constants. For a complete list, see the `PdiConst.h` file.

| Constant                  | Description                     |
|---------------------------|---------------------------------|
| <code>kPdiPRN_ADR</code>  | The <code>ADR</code> property.  |
| <code>kPdiPRN_BDAY</code> | The <code>BDAY</code> property. |

## Personal Data Interchange Library

### Property Type Constants

---

| Constant            | Description               |
|---------------------|---------------------------|
| kPdiPRN_BEGIN       | The BEGIN property.       |
| kPdiPRN_BEGIN_VCARD | The BEGIN:VCARD property. |

## Property Type Constants

You use the property type constants to specify the data type of a property.

| Constant             | Value | Description                                       |
|----------------------|-------|---------------------------------------------------|
| kPdiType_URI         | 0     | The data is a uniform resource identifier.        |
| kPdiType_UTC_OFFSET  | 1     | The data is an offset from UTC to local time.     |
| kPdiType_RECUR       | 2     | The data is a specification of a recurrence rule. |
| kPdiType_PERIOD      | 3     | The data is a precise period of time.             |
| kPdiType_CAL_ADDRESS | 4     | Calendar user data.                               |
| kPdiType_BINARY      | 5     | Binary data.                                      |
| kPdiType_TEXT        | 6     | Text data.                                        |
| kPdiType_FLOAT       | 7     | Floating-point data.                              |
| kPdiType_DURATION    | 8     | Time duration data.                               |
| kPdiType_DATE_TIME   | 9     | Calendar date and time data.                      |
| kPdiType_DATE        | 10    | Date data.                                        |
| kPdiType_INTEGER     | 11    | Signed integer data.                              |
| kPdiType_TIME        | 12    | Time-of-day data.                                 |

## Property Value Field Constants

The `PdiConst.h` file defines several property value field constants that you can use to specify the position of a PDI property value field

in functions that use fields. The property value field constants have the following format:

`kPdiPVF_propertyValueField`

where *propertyValueField* is replaced by a property value field name.

The following table shows examples of property name constants. For a complete list, see the `PdiConst.h` file.

| Constant                             | Description                                                                  |
|--------------------------------------|------------------------------------------------------------------------------|
| <code>kPdiPVF_ADR_POST_OFFICE</code> | The property value field that stores the post office portion of the address. |
| <code>kPdiPVF_ADR_EXTENDED</code>    | The property value field that stores the extended portion of the address.    |
| <code>kPdiPAN_ADR_COUNTRY</code>     | The property value field that stores the country portion of the address.     |

## Property Value Format Constants

Some properties have **structured values**, which are values that contain multiple fields. These fields are typically separated by commas or semicolons in the vObject input or output stream. You use the property value format constants with the [`PdiReadPropertyField\(\)`](#) and [`PdiWritePropertyStr\(\)`](#) functions to specify how to handle fields in a structured value.

## Personal Data Interchange Library

### Property Value Format Constants

---

| Constant             | Value | Description                                                                                                                                                                                           |
|----------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiNoFields         | 0     | There are no fields in the property value; <a href="#">PdiReadPropertyField()</a> reads the entire value, or <a href="#">PdiWritePropertyStr()</a> specifies that the entire value should be written. |
| kPdiCommaFields      | 1     | Fields are separated with comma (",") characters; <a href="#">PdiReadPropertyField()</a> reads one field, or <a href="#">PdiWritePropertyStr()</a> specifies that one field should be written.        |
| kPdiSemicolonFields  | 2     | Fields are separated with semicolon (";") characters; <a href="#">PdiReadPropertyField()</a> reads one field, or <a href="#">PdiWritePropertyStr()</a> specifies that one field should be written.    |
| kPdiDefaultFields    | 4     | The parser decides the property value format, based on the property name.                                                                                                                             |
| kPdiConvertComma     | 8     | Fields are separated with comma characters; <a href="#">PdiReadPropertyField()</a> reads the entire value and converts each comma into a newline ("\n") character.                                    |
| kPdiConvertSemicolon | 16    | Fields are separated with semicolon characters; <a href="#">PdiReadPropertyField()</a> reads the entire value and converts each semicolon into a newline ("\n") character.                            |

---

## Reader and Writer Options Constants

You use the reader and writer option constants to control how the PDI reader (parser) reads values from the input stream or to control how the PDI writer (generator) writes values to the output stream.

| Constant                  | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiEnableFolding         | 1     | <p>Enables folding of properties in the output stream.</p> <p><b>Folding</b> is a mechanism for breaking long lines to allow them to be transmitted without change. If you specify this flag, the PDI library folds long lines.</p> <p>Note that folding is not compatible with earlier versions of the Palm OS®.</p> <p>Also note that other encoding formats, including quoted-printable and Base 64, define their own mechanisms for splitting long lines.</p> |
| kPdiEnableQuotedPrintable | 2     | <p>Enables quoted-printable encoding in the output stream and makes it the default encoding.</p> <p>This is an encoding format for non-ASCII values. You must have this enabled for compatibility with earlier versions of the Palm OS.</p> <p>If you do not specify this option, the default encoding is Base 64.</p>                                                                                                                                            |

## Personal Data Interchange Library

### Reader and Writer Options Constants

---

| Constant                   | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiEscapeMultiFieldValues | 4     | <p>For compatibility with earlier versions of the Palm OS.</p> <p>You must enable this for compatibility with earlier versions of the Palm OS. However, some non-Palm PDI software does not support this format.</p> <p>For more information about compatibility with earlier versions of the Palm OS, see <a href="#">Format Compatibility</a> in the <i>Palm OS Programmer's Companion</i>, vol. II, <i>Communications</i>.</p> |
| kPdiPalmCompatibility      | 6     | <p>This is a combination of kPdiEnableQuotedPrintable   kPdiEscapeMultiFieldValues.</p> <p>It forces the PDI writer to generate output that is compatible with earlier versions of the Palm OS.</p>                                                                                                                                                                                                                               |
| kPdiEnableB                | 8     | <p>Enables base 64 encoding in the output stream, and tells the PDI writer to output "ENCODING=B" instead of "ENCODING=BASE64" when encoding a value with Base 64.</p> <p>Note: the vCard 3.0 standard has replaced the earlier ENCODING=BASE64 with ENCODING=B. The meaning is the same.</p>                                                                                                                                     |
| kPdiOpenParser             | 8     | <p>Specifies that the PDI reader is open to all formats, including Palm and others.</p>                                                                                                                                                                                                                                                                                                                                           |

## Reader Event Constants

The PDI reader event constants specify the events that the reader has handled during the current read operation. The event values are combined together and stored in the `events` field of the PDI reader object. You can use them to test whether the reader handled a certain event.

| Constant                                     | Value | Description                                                                               |
|----------------------------------------------|-------|-------------------------------------------------------------------------------------------|
| <code>kPdiEOFEventMask</code>                | 1     | End of file was reached.                                                                  |
| <code>kPdiGroupNameEventMask</code>          | 2     | A group name was found.                                                                   |
| <code>kPdiPropertyNameEventMask</code>       | 4     | A property name was found.                                                                |
| <code>kPdiParameterNameEventMask</code>      | 8     | A parameter name was found.                                                               |
| <code>kPdiParameterValueEventMask</code>     | 16    | A parameter value was found.                                                              |
| <code>kPdiPropertyDefinedEventMask</code>    | 32    | A property definition was found; this implies that the ":" separator character was found. |
| <code>kPdiPropertyValueEventMask</code>      | 64    | An entire property value was found                                                        |
| <code>kPdiPropertyValueFieldEventMask</code> | 128   | A value field was found; this implies that the ";" separator character was found.         |
| <code>kPdiPropertyValueItemEventMask</code>  | 256   | A value item was found; this implies that the "," separator character was found.          |

## Personal Data Interchange Library

### Value Type Constants

---

| Constant                            | Value | Description                                                                                        |
|-------------------------------------|-------|----------------------------------------------------------------------------------------------------|
| kPdiPropertyValueMoreCharsEventMask | 512   | The buffer that you provided was not large enough. The superfluous characters have been discarded. |
| kPdiBeginObjectEventMask            | 1024  | The object begin indicator BEGIN was reached.                                                      |
| kPdiEndObjectEventMask              | 2048  | The object end indicator END was reached.                                                          |

---

## Value Type Constants

You can use the following constants to specify data typing information for the [PdiWritePropertyBinaryValue\(\)](#), [PdiWritePropertyFields\(\)](#), and [PdiWritePropertyValue\(\)](#) functions.

| Constant           | Value | Description                                                                                                                                                                                     |
|--------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiWriteData      | 0     | The value is data. The PDI writer does not compute a character set. You can use this for binary data or pure ASCII data.                                                                        |
| kPdiWriteText      | 8     | The value is text data. The PDI writer parses the data character by character to compute the correct charset and character encoding for the data.                                               |
| kPdiWriteMultiline | 16    | Explicitly specifies that the value contains special characters, such as newlines, and must be encoded. If this flag is not specified, the encoding is determined by the applied character set. |

## PDI Library Functions

### PdiDefineReaderDictionary Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Installs a new custom dictionary for use with a PDI reader object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | <pre>PdiDictionary *PdiDefineReaderDictionary     (UInt16 libRefnum, PdiReaderType *ioReader,      PdiDictionary *dictionary,      Boolean disableMainDictionary)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioReader</i><br/>The PDI reader object with which to associate the dictionary. This object must have previously been created by a call to the <a href="#">PdiReaderNew()</a> function.</p> <p>→ <i>dictionary</i><br/>A pointer to a dictionary object that was created by the . The dictionary object is an array of binary data.</p> <p>→ <i>disableMainDictionary</i><br/>If <code>true</code>, the main reader dictionary is disabled, and only this new dictionary is searched for terms; if <code>false</code>, the new dictionary supplements the main dictionary.</p>                                                                                                                              |
| <b>Returns</b>     | Returns a pointer to the previously installed custom dictionary, or <code>NULL</code> if there was not a previously installed custom dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Comments</b>    | <p>This function installs a dictionary for use with the <code>ioReader</code> object. The dictionary contains the syntax for extensions or replacements of the PDI properties about which the PDI reader knows. The reader knows about properties specified in one of the vObject standards, including the vCard or vCal standards.</p> <p>You can uninstall the current custom dictionary by specifying <code>NULL</code> as the value of the <code>dictionary</code> parameter,</p> <p>Note that the dictionary must have previously been compiled by the dictionary tool. For more information, review the PDI sample code, which you can find on the Palm Developer's Knowledge Base at <a href="http://www.palmos.com/dev/tech/kb">http://www.palmos.com/dev/tech/kb</a>.</p> |

## PdiDefineResizing Function

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                         |                     |                                       |                     |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|---------------------|---------------------------------------|---------------------|
| <b>Purpose</b>                          | Defines the sizing information to use when automatically resizing a buffer. PDI reader objects read information from the input stream into a buffer and automatically adjust the buffer size as required.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                         |                     |                                       |                     |
| <b>Declared In</b>                      | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                         |                     |                                       |                     |

| <b>Comments</b>                         | <p>This function redefines the values to use when resizing a buffer. It does not perform any other actions.</p> <p>The resizing values are used if your reader runs out of buffer space when storing input data during the processing of a property value. If possible, the reader resizes its internal buffer, using the values that you supply in this function.</p> <p>The default resizing values apply if you do not call this function. The default values are:</p> <table><tr><td><code>kPdiDefaultBufferDeltaSize</code></td><td><code>0x0010</code></td></tr><tr><td><code>kPdiDefaultBufferMaxSize</code></td><td><code>0x3FFF</code></td></tr></table> | <code>kPdiDefaultBufferDeltaSize</code> | <code>0x0010</code> | <code>kPdiDefaultBufferMaxSize</code> | <code>0x3FFF</code> |

## **PdiDefineWriterDictionary Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Installs a new custom dictionary for use with a PDI writer object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>PdiDictionary *PdiDefineWriterDictionary     (UInt16 libRefnum, PdiWriterType *ioWriter,      PdiDictionary *dictionary,      Boolean disableMainDictionary)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object with which to associate the dictionary. This object must have previously been created by a call to the <a href="#">PdiWriterNew()</a> function.</p> <p>→ <i>dictionary</i><br/>A pointer to a dictionary object that was created by the . The dictionary object is an array of binary data.</p> <p>→ <i>disableMainDictionary</i><br/>If <code>true</code>, the main dictionary is disabled, and only this new dictionary is searched for terms; if <code>false</code>, the new dictionary supplements the main dictionary.</p>                                                                                                                                       |
| <b>Returns</b>     | Returns a pointer to the previously installed custom dictionary, or <code>NULL</code> if there was not a previously installed custom dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | <p>This function installs a dictionary for use with the <code>ioWriter</code> object. The dictionary contains the syntax for extensions or replacements of the PDI properties about which the PDI writer knows. The writer knows about properties specified in one of the vObject standards, including the vCard or vCal standards.</p> <p>You can uninstall the current custom dictionary by specifying <code>NULL</code> as the value of the <code>dictionary</code> parameter,</p> <p>Note that the dictionary must have previously been compiled by the dictionary tool. For more information, review the PDI sample code, which you can find on the Palm Developer's Knowledge Base at <a href="http://www.palmos.com/dev/tech/kb/">http://www.palmos.com/dev/tech/kb/</a>.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Tells the PDI library to enter into a recursively-defined object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>     | <code>Err PdiEnterObject (UInt16 libRefnum,<br/>PdiReaderType *ioReader)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioReader</i><br/>The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew()</a> function.</p>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Comments</b>      | <p>Some <code>vObjects</code> recursively define other <code>vObjects</code>. Your application can choose whether or not to enter and parse the recursively defined objects.</p> <p>If you want to parse the nested object definition, you need to call this function; otherwise, all of the properties of the nested object are skipped when the next call is made to the <a href="#">PdiReadProperty()</a> or <a href="#">PdiReadPropertyName()</a> functions.</p> <p>Call this function after a <code>BEGIN_vObject</code> statement of the nested object has been parsed.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## PdiLibClose Function

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Close the PDI library after your application has finished with it.                                                                                                                                                                                        |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <code>Err PdiLibClose (UInt16 libRefnum)</code>                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p>                                                                                                                                                                                           |
| <b>Returns</b>     | <p>Returns 0 if no other application uses the library. You may need to call <a href="#">SysLibRemove()</a> to remove the PDI library from the system library table.</p> <p>Returns <code>pdiErrCloseFailed</code> if the library could not be closed.</p> |
| <b>Comments</b>    | You should call this function after your application has finished with the PDI library, to allow the resources to be recovered.                                                                                                                           |

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [PdiLibOpen\(\)](#)

## **PdiLibOpen Function**

**Purpose**           Opens the PDI library for use by your application.

**Declared In**     `PdiLib.h`

**Prototype**       `Err PdiLibOpen(UInt16 libRefnum)`

**Parameters**      `→ libRefnum`  
                    The PDI library reference number.

**Returns**           Returns `errNone` if successful, and an error code if not successful.

**Comments**        You must call this function before calling any of the other PDI functions.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [PdiLibClose\(\)](#)

## **PdiParameterPairTest Macro**

**Purpose**           Determines if the reader has already parsed the specified parameter value or name-value pair.

**Declared In**     `PdiLib.h`

**Prototype**       `#define PdiParameterPairTest (reader, pair)`

**Parameters**      `→ reader`  
                    The PDI reader object, which was created by a previous call to the [PdiReaderNew\(\)](#) function.  
  
                    `→ pair`  
                    The ID of the parameter. This must be one of the [Parameter Value Constants](#).

**Returns**           Returns `true` if the specified parameter name-value pair has been parsed for the current property, and `false` if not.

**Comments**        Some vObject generators do not specify the parameter name if the name is considered evident from the context. This means that both of the following constructs are considered proper:

Name=Value

Value

The `PdiParameterPairTest` macro returns `true` if the value has been parsed in either format. For example,

---

```
PdiParameterPairTest(reader, kPdiPAV_TYPE_WORK)
```

---

returns `true` for either of the following:

Type=WORK

WORK

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## PdiReaderDelete Function

**Purpose**    Delete a PDI reader object that is associated with the specified library number.

**Declared In**    `PdiLib.h`

**Prototype**    `void PdiReaderDelete(UInt16 libRefnum,  
                        PdiReaderType **ioReader)`

**Parameters**     $\rightarrow$  *libRefnum*  
                    The PDI library reference number.

$\leftrightarrow$  *ioReader*  
                    A pointer to the PDI reader object, which was created by a previous call to the [PdiReaderNew\(\)](#) function.

**Returns**    Returns nothing.

**Comments**    This function deletes the UDAR reader object associated with the reader object and frees the memory that was allocated for the reader object. The `ioReader` parameter is set to `NULL`.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**    [PdiReaderNew\(\)](#)

## PdiReaderNew Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Create and initialize a new PDI reader object for use with the specified PDI library number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>     | <code>PdiReaderType *PdiReaderNew(UInt16 libRefnum,<br/>UDAREaderType *input, UInt16 version)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>input</i><br/>The Unified Data Access (UDA) input object associated with the reader.</p> <p>→ <i>version</i><br/>Options to control the parsing behavior of the reader. You can use a combination of the <a href="#">Reader and Writer Options Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                          |
| <b>Returns</b>       | Returns a pointer to the new PDI reader object. Returns NULL if the reader cannot be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Comments</b>      | <p>The current implementation of the <code>PdiReaderNew</code> function does not make use of the <code>optionFlags</code> settings because the reader knows how to adapt itself to all of the supported formats. The options will be used in future versions.</p> <p>The <code>input</code> value is a UDA object for reading data from an input stream that can be connected to various data sources. For example, you can use a <code>UDAExchangeReader</code> to read data from the Exchange Manager, and you can use a <code>UDAStringReader</code> to read data from a string. For more information about the UDA Manager, see <a href="#">Chapter 86, “Unified Data Access Manager.”</a></p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>See Also</b>      | <a href="#">PdiReaderDelete()</a> , <a href="#">PdiWriterNew()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## PdiReadParameter Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Read a single parameter name and its value from an input stream.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>     | <code>Err PdiReadParameter(UInt16 libRefnum,<br/>PdiReaderType *ioReader)</code>                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioReader</i><br/>The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew()</a> function.</p>                                                                                                                                                                                                                                                               |
| <b>Returns</b>       | <p>0<br/>The parameter and its value were read successfully.</p> <p><code>kPdiReadError</code><br/>The parameter and its value could not be successfully read from the input stream.</p> <p>This function initializes the <code>parameterName</code> and <code>parameter</code> fields of the <code>ioReader</code> object.</p> <p>This function sets the appropriate bits in the reader's <code>parameterValues</code> field if the parameter name is recognized.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                    |

|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | Returns <code>errNone</code> if successful. Returns <code>kPdiReadError</code> if an error occurs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>      | <p>The <code>PdiReadProperty</code> function reads a property name and its parameters, by reading until it encounters the PDI “:” separator character.</p> <p>This function looks each name up in the properties dictionary, and sets the appropriate bit in the <code>ioReader</code> object structure to indicate that property-parameter pair has been read. The properties dictionary stores information about properties that are considered well known, as described in <a href="#">The PDI Library Properties Dictionary</a> in <a href="#">Chapter 3, “Personal Data Interchange,”</a> in <i>Palm OS Programmer’s Companion</i>, vol. II, <i>Communications</i>.</p> <p>To read a property, you call <code>PdiReadProperty</code>, followed by a call or calls to the <a href="#">PdiReadPropertyField()</a> function to read the property value. For more information, see <a href="#">Reading Properties</a> in <a href="#">Chapter 3, “Personal Data Interchange,”</a> in <i>Palm OS Programmer’s Companion</i>, vol. II, <i>Communications</i>.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## PdiReadPropertyField Function

|                    |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Read one field of a property value. The property value can be structured to contain multiple fields that are separated by commas or semicolons.                                                                      |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err PdiReadPropertyField(UInt16 libRefnum,     PdiReaderType *ioReader, Char **bufferPP,     UInt16 bufferSize, UInt16 readMode)</pre>                                                                          |
| <b>Parameters</b>  | <p>→ <code>libRefnum</code><br/>The PDI library reference number.</p> <p>→ <code>ioReader</code><br/>The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew()</a> function.</p> |

## Personal Data Interchange Library

### *PdiReadPropertyField*

---

↔ *bufferPP*

A pointer to a pointer to the buffer into which the field characters are stored. Set this value to `NULL` to allow the PDI library to manage it.

Note that the PDI library may need to resize the buffer; thus, the value of this parameter might change.

→ *bufferSize*

The size, in bytes, of the input buffer for reading the field.

You can use the `PdiResizableBuffer` constant to specify that the PDI Library can automatically resize the buffer as required.

If you do not specify the `PdiResizableBuffer` value, then the PDI library assumes that `buffer` cannot be moved, and that its size is fixed.

→ *readMode*

The format of the fields in the property value. Use one of the [Property Value Format Constants](#).

**Returns**     0

The field was read successfully.

`kPdiNoMoreFieldsError`

There are no more fields to read because the entire value has already been read.

`kPdiMoreCharsError`

The buffer is not large enough to store the entire field.

**Comments**

The value returned in the `buffer` is terminated with the “\0” character.

If the field is an empty string, the buffer is erased from memory, and the value of `buffer` is set to `NULL`.

If you specify `kPdiResizableBuffer` for the value of the `bufferSize` parameter, and the buffer needs more space, `PdiReadPropertyField` resizes the buffer for you, which may cause the value of `buffer` to be modified.

This function initializes the `propertyValue` and `fieldNum` fields of the `ioReader` object.

To read a property, you usually call the [PdiReadProperty\(\)](#) function, followed by a call or calls to `PdiReadPropertyField` to

read the property value. For more information, see [Reading Properties](#) in [Chapter 3](#), “[Personal Data Interchange](#),” in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew\(\)](#), [PdiReadProperty\(\)](#), [PdiReadPropertyName\(\)](#), [PdiReadParameter\(\)](#)

## PdiReadPropertyName Function

**Purpose** Read a property name from an input stream. Use this function when you want to parse and process each parameter individually.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiReadPropertyName(UInt16 libRefnum,  
PdiReaderType *ioReader)`

**Parameters** → `libRefnum`

The PDI library reference number.

→ `ioReader`

The PDI reader object, which was created by a previous call to the [PdiReaderNew\(\)](#) function.

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** The `PdiReadProperty` function reads a property name only, reading until it encounters the PDI “:” separator character, or until it encounters the first parameter “,” separator character.

This function initializes the `property` and `propertyName` fields of the `ioReader` object.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew\(\)](#), [PdiReadPropertyField\(\)](#), [PdiReadProperty\(\)](#), [PdiReadParameter\(\)](#)

## PdiSetCharset Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Force the character set of the next property value that is written by the specified PDI writer.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>     | <pre>Err PdiSetCharset(UInt16 libRefnum,<br/>                  PdiWriterType *ioWriter,<br/>                  CharEncodingType charset)</pre>                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object, which was created by a previous call to the <a href="#">PdiWriterNew()</a> function.</p> <p>→ <i>charset</i><br/>The character set to use for the property value. This must be one of the following <a href="#">CharEncodingType</a> values:</p> <pre>charEncodingAscii<br/>charEncodingISO8859_1<br/>charEncodingShiftJIS<br/>charEncodingISO2022Jp</pre> |
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>      | <p>This function tells <code>ioWriter</code> to use the specified <code>charSet</code> for the next property value that it writes, rather than computing a character set for that value.</p> <p>You can determine the current character setting by examining the <code>charset</code> field of your PDI writer object.</p>                                                                                                                                                 |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>See Also</b>      | <a href="#">PdiSetEncoding()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## PdiSetEncoding Function

|                      |                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Force the encoding of the current property value.                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>     | <pre>Err PdiSetEncoding(UInt16 libRefnum,<br/>                  PdiWriterType *ioWriter, UInt16 encoding)</pre>                                                                                                                                                                                                                                     |

## PdiWriteBeginObject Function

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Writes a vObject begin tag to an output stream.                                                                                                                                                          |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                    |
| <b>Prototype</b>   | <pre>Err PdiWriteBeginObject(UInt16 libRefnum,<br/>                        PdiWriterType *ioWriter, UInt16 objectNameID)</pre>                                                                           |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object, which was created by a previous call to the <a href="#">PdiWriterNew()</a> function.</p> |

→ *objectNameID*

The object name ID. This must be one of the [Property Name Constants](#) that begins an object, including the following:

kPdiPRN\_BEGIN\_VCAL

kPdiPRN\_BEGIN\_VCAL

kPdiPRN\_BEGIN\_VCARD

kPdiPRN\_BEGIN\_VEVENT

kPdiPRN\_BEGIN\_VFREEBUSY

kPdiPRN\_BEGIN\_VJOURNAL

kPdiPRN\_BEGIN\_VTIMEZONE

kPdiPRN\_BEGIN\_VTODO

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Call this function to begin writing a vObject to the output stream. It writes a begin tag such as “BEGIN:VCARD” to the output stream.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteEndObject\(\)](#), [PdiWriteProperty\(\)](#)

## PdiWriteEndObject Function

**Purpose** Writes a vObject end tag to an output stream.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiWriteEndObject(UInt16 libRefnum,  
PdiWriterType *ioWriter, UInt16 objectNameID)`

**Parameters** → *libRefnum*

The PDI library reference number.

→ *ioWriter*

The PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

→ *objectNameID*

The object name ID. This must be one of the [Property Name Constants](#) that ends an object, including the following:

kPdiPRN\_END\_VCAL

```
kPdiPRN_END_VCAL
kPdiPRN_END_VCARD
kPdiPRN_END_VEVENT
kPdiPRN_END_VFREEBUSY
kPdiPRN_END_VJOURNAL
kPdiPRN_END_VTIMEZONE
kPdiPRN_END_VTODO
```

|                      |                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not successful.                                                                |
| <b>Comments</b>      | Call this function to finish writing a <code>vObject</code> to the output stream. It writes a end tag such as “END:VCARD” to the output stream. |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                             |
| <b>See Also</b>      | <a href="#">PdiWriteBeginObject()</a> , <a href="#">PdiWriteProperty()</a>                                                                      |

## PdiWriteParameter Function

|                    |                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write a parameter, and optionally its name, to an output stream.                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | <pre>Err PdiWriteParameter(UInt16 libRefnum,     PdiWriterType *ioWriter, UInt16 parameter,     Boolean parameterName)</pre>                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object, which was created by a previous call to the <a href="#">PdiWriterNew()</a> function.</p> <p>→ <i>parameter</i><br/>The ID of the parameter. This must be one of the <a href="#">Parameter Value Constants</a>.</p> |

## Personal Data Interchange Library

### *PdiWriteParameter*

---

→ *parameterName*

If this is `true`, the parameter name, followed by the “=” symbol, followed by the parameter value is written to the output stream.

If this is `false`, only the parameter value is written to the output stream.

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a parameter to the output stream. To write a property, you usually call the [PdiWriteProperty\(\)](#) function, followed by calls to `PdiWriteParameter` to write any parameters, followed by a call to the [PdiWritePropertyValue\(\)](#) function to write the property value. For more information, see [Writing Properties](#) in [Chapter 3, “Personal Data Interchange,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

You can use the `parameterName` argument to specify that you want the parameter name written as well as the parameter value. For example, the following table shows what is written if the value of parameter is `kPdipAV_TYPE_HOME`.

| Value of <code>parameterName</code> | Data written to output stream |
|-------------------------------------|-------------------------------|
| <code>true</code>                   | TYPE=HOME                     |
| <code>false</code>                  | HOME                          |

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty\(\)](#), [PdiWritePropertyValue\(\)](#), [PdiWritePropertyFields\(\)](#), [PdiWritePropertyStr\(\)](#), [PdiWriteParameterStr\(\)](#)

## PdiWriteParameterStr Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Write a parameter name and the parameter value to an output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <pre>Err PdiWriteParameterStr(UInt16 libRefnum,     PdiWriterType *ioWriter,     const Char *parameterName,     const Char *parameterValue)</pre>                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object, which was created by a previous call to the <a href="#">PdiWriterNew()</a> function.</p> <p>→ <i>parameterName</i><br/>The name of the parameter. If the value of this is the empty string or NULL, only the parameter value is written.</p> <p>→ <i>parameterValue</i><br/>The parameter value string.</p>                                                                                              |
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Comments</b>      | <p>This function writes the parameter name, followed by the “=” symbol, followed by the parameter value, to the output stream. If <code>parameterName</code> is NULL, or if its value is the empty string, just the parameter value is written.</p> <p>This function is similar to the <a href="#">PdiWriteParameter()</a> function. The difference is that <code>PdiWriteParameterStr</code> takes the name and value of the parameter as strings, while <code>PdiWriteParameter</code> takes them as ID constants.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>See Also</b>      | <a href="#">PdiWriteProperty()</a> , <a href="#">PdiWritePropertyValue()</a> ,<br><a href="#">PdiWritePropertyFields()</a> , <a href="#">PdiWritePropertyStr()</a> ,<br><a href="#">PdiWriteParameter()</a>                                                                                                                                                                                                                                                                                                              |

## PdiWriteProperty Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Writes a property name to an output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | <pre>Err PdiWriteProperty(UInt16 libRefnum,     PdiWriterType *ioWriter,     UInt16 propertyNameID)</pre>                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>ioWriter</i><br/>The PDI writer object, which was created by a previous call to the <a href="#">PdiWriterNew()</a> function.</p> <p>→ <i>propertyNameID</i><br/>The property name to write. This must be one of the <a href="#">Property Name Constants</a>.</p>                                                                                                                                         |
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Comments</b>      | To write a property, you usually call <code>PdiWriteProperty</code> , followed by calls to the <a href="#">PdiWriteParameter()</a> function to write any parameters, followed by a call to the <a href="#">PdiWritePropertyValue()</a> function to write the property value. For more information, see <a href="#">Writing Properties</a> in <a href="#">Chapter 3, “Personal Data Interchange,”</a> in <i>Palm OS Programmer’s Companion</i> , vol. II, <i>Communications</i> . |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>See Also</b>      | <a href="#">PdiWritePropertyValue()</a> , <a href="#">PdiWritePropertyFields()</a> , <a href="#">PdiWritePropertyStr()</a> , <a href="#">PdiWriteParameter()</a>                                                                                                                                                                                                                                                                                                                 |

## PdiWritePropertyBinaryValue Function

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write a binary property value to an output stream.                                                                                             |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                                                                                          |
| <b>Prototype</b>   | <pre>Err PdiWritePropertyBinaryValue(UInt16 libRefnum,     PdiWriterType *ioWriter, const Char *buffer,     UInt16 size, UInt16 options)</pre> |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p>                                                                                |

→ *ioWriter*

The PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

→ *buffer*

A buffer that contains the binary data.

→ *size*

The number of bytes of data to write from the buffer.

→ *options*

The data type. This must be a combination of one or more of the [Value Type Constants](#).

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a binary data property value, such as a sound or an image.

This function encodes the data when it is written. The character set that gets applied to the data is not computed by this function; however, you can call the [PdiSetCharset\(\)](#) function to set the character set.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty\(\)](#), [PdiWritePropertyFields\(\)](#), [PdiWritePropertyValue\(\)](#)

## PdiWritePropertyFields Function

**Purpose** Write a structured property value with multiple fields to an output stream.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiWritePropertyFields(UInt16 libRefnum,  
PdiWriterType *ioWriter, Char *fields[],  
UInt16 fieldNumber, UInt16 options)`

**Parameters** → *libRefnum*

The PDI library reference number.

→ *ioWriter*

The PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

→ *fields*

An array of strings, each of which is a field of the property value. Individual fields can be NULL.

→ *fieldNumber*

The number of fields in the `Fields` array.

→ *options*

The data type. This must be a combination of one or more of the [Value Type Constants](#).

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a property value that contains multiple fields.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWritePropertyValue\(\)](#),  
[PdiWritePropertyBinaryValue\(\)](#),  
[PdiReadPropertyField\(\)](#)

## PdiWritePropertyStr Function

**Purpose** Writes the name of a property to the output stream, and specifies the property value's structure for subsequent write operations.

**Declared In** `PdiLib.h`

**Prototype**

```
Err PdiWritePropertyStr(UInt16 libRefnum,
    PdiWriterType *ioWriter,
    const Char *propertyName, UInt8 writeMode,
    UInt8 requiredFields)
```

**Parameters** → *libRefnum*  
The PDI library reference number.

→ *ioWriter*  
The PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

→ *propertyName*  
The name of the property to write.

→ *writeMode*  
The format of the fields in the property value. Use one of the following [Property Value Format Constants](#):

`kPdiNoFields`

`kPdiCommaFields`

`kPdiSemicolonFields`

→ *requiredFields*

The number of required fields for the value. This is usually set to 1.

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function when you are writing a property that is not in the dictionary, or when you are writing a property that uses value formatting that differs from the standard formatting stored in the dictionary for the property name.

This function writes the property name to the output stream, and then establishes the structure of the property's value, including the number of required fields and the separator character for those fields. After calling this function, the next call to the [PdiWritePropertyValue\(\)](#) or [PdiWritePropertyFields\(\)](#) functions correctly writes the property value.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty\(\)](#), [PdiWritePropertyValue\(\)](#), [PdiWritePropertyFields\(\)](#), [PdiWriteParameter\(\)](#)

## PdiWritePropertyValue Function

**Purpose** Write a string to the output stream as the entire value of a property.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiWritePropertyValue(UInt16 libRefnum,  
PdiWriterType *ioWriter, Char *buffer,  
UInt16 options)`

**Parameters** → *libRefnum*  
The PDI library reference number.

→ *ioWriter*  
The PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

→ *buffer*

The input buffer that contains the string to be written.

→ *options*

The data type. This must be a combination of one or more of the [Value Type Constants](#).

**Returns** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a property value that contains a single field.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty\(\)](#), [PdiWritePropertyFields\(\)](#), [PdiWriteParameter\(\)](#), [PdiWritePropertyBinaryValue\(\)](#)

## PdiWriterDelete Function

**Purpose** Delete a PDI output stream object.

**Declared In** `PdiLib.h`

**Prototype** `void PdiWriterDelete(UInt16 libRefnum,  
PdiWriterType **ioWriter)`

**Parameters** → *libRefnum*

The PDI library reference number.

↔ *ioWriter*

A pointer to the PDI writer object, which was created by a previous call to the [PdiWriterNew\(\)](#) function.

**Returns** Returns nothing.

**Comments** This function frees the memory that was allocated for the writer object. The `ioWriter` parameter is set to `NULL`.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriterNew\(\)](#)

## PdiWriterNew Function

|                      |                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Initializes a new PDI writer object for use with the specified library number.                                                                                                                                                                                                                                                      |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>     | <code>PdiWriterType *PdiWriterNew(UInt16 libRefnum,<br/>UDAWriterType *output, UInt16 version)</code>                                                                                                                                                                                                                               |
| <b>Parameters</b>    | <p>→ <i>libRefnum</i><br/>The PDI library reference number.</p> <p>→ <i>output</i><br/>The Unified Data Access (UDA) output object associated with the writer.</p> <p>→ <i>version</i><br/>Options to control the behavior of the writer. You can use a combination of the <a href="#">Reader and Writer Options Constants</a>.</p> |
| <b>Returns</b>       | Returns a pointer to the new PDI writer object. Returns NULL if the reader cannot be created.                                                                                                                                                                                                                                       |
| <b>Comments</b>      | The media pointer is copied into a field in the writer object; thus, you do not need to retain your copy.                                                                                                                                                                                                                           |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                 |
| <b>See Also</b>      | <a href="#">PdiWriterDelete()</a> , <a href="#">PdiReaderNew()</a>                                                                                                                                                                                                                                                                  |

# Unified Data Access Manager

---

This chapter provides reference material for the Unified Data Access (UDA) Manager, which provides a mechanism for abstracting read and write access to different kinds of source and destination media, including memory and the Exchange Manager.

The Personal Data Interchange (PDI) reader and writer objects use UDA objects, and you must create UDA objects to use the PDI functions.

This chapter discusses the following topics:

- [UDA Manager Data Structures](#)
- [UDA Manager Constants](#)
- [UDA Manager Functions](#)
- [UDA Object Creation Functions](#)

The header file `UDAMgr.h` declares the Unified Data Access Manager API.

You use the UDA Manager in conjunction with the PDI library. For more information about the PDI library, see [Chapter 85, “Personal Data Interchange Library.”](#)

[Chapter 3, “Personal Data Interchange,”](#) in the *Palm OS Programmer’s Companion*, vol. II, *Communications*, provides examples of using the UDA functions with the PDI library.

## UDA Manager Data Structures

### UDABufferSize Typedef

**Purpose** The UDABufferSize type is a simple typedef that defines the size of buffers used with UDA read functions.

**Prototype** `typedef UInt16 UDABufferSize`

### UDAObjectType Struct

**Purpose** The UDAObjectType is the base class for all UDA objects, and defines the common properties of all of the objects.

**Prototype** `typedef struct UDAObjectTag {  
 UInt16 optionFlags;  
 UDADeleteFunction deleteF;  
 UDAControlFunction controlF;  
} UDAObjectType`

#### Field Descriptions

|                          |                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------|
| <code>optionFlags</code> | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| <code>deleteF</code>     | The delete function associated with this UDA object.                                                       |
| <code>controlF</code>    | The control function associated with this UDA object.                                                      |

### UDAFilterType Struct

**Purpose** The UDAFilterType represents UDA Filters, which take input from a UDA Reader or UDA Filter, perform some encoding or decoding operation, and output the data to a memory buffer.

**Prototype** `typedef struct UDAFilterTag {  
 UInt16 optionFlags;`

```

        UDADeleteFunction    deleteF;
        UDAControlFunction   controlF;
        UDAReadFunction      readF;
        UDARedReaderType*    upperReader;
    } UDAFilterType

```

### Field Descriptions

|             |                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------|
| optionFlags | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> .                 |
| deleteF     | The delete function associated with this UDA object.                                                                       |
| controlF    | The control function associated with this UDA object.                                                                      |
| readF       | The read function associated with this UDA object.                                                                         |
| upperReader | The <a href="#">UDARedReaderType</a> or <a href="#">UDAFilterType</a> object that reads the data that this object outputs. |

### UDARedReaderType Struct

**Purpose** The UDARedReaderType represents UDA Readers, which read input from a medium.

**Prototype**

```

typedef struct UDARedReaderTag {
    UInt16                optionFlags;
    UDADeleteFunction      deleteF;
    UDAControlFunction     controlF;
    UDAReadFunction        readF;
} UDARedReaderType

```

#### Field Descriptions

|             |                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------|
| optionFlags | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| deleteF     | The delete function associated with this UDA object.                                                       |
| controlF    | The control function associated with this UDA object.                                                      |
| readF       | The read function associated with this UDA object.                                                         |

#### UDAWriterType Struct

**Purpose** The UDAWriterType represents UDA Writers, which take data from a UDA Reader or UDA Filter and write the data to an output medium.

**Prototype**

```
typedef struct UDAWriterTag {
    UInt16                optionFlags;
    UDADeleteFunction      deleteF;
    UDAControlFunction     controlF;
    UDAWriteFunction        initiateWriteF;
    UDAFlushFunction        flushF;
    UDAReaderType*         upperReader;
} UDAWriterType
```

#### Field Descriptions

|             |                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------|
| optionFlags | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| deleteF     | The delete function associated with this UDA object.                                                       |
| controlF    | The control function associated with this UDA object.                                                      |

|                             |                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------|
| <code>initiateWriteF</code> | The write function associated with this UDA object.                                   |
| <code>flushF</code>         | The flush function associated with this UDA object.                                   |
| <code>upperReader</code>    | The <a href="#">UDAREaderType</a> object that reads the data that this object writes. |

## UDA Manager Constants

This section describes the constants used with the UDA Manager, which include the following constant types:

- [Control Flags](#)
- [Error Constants](#)
- [Object Option Flags](#)
- [Miscellaneous Constants](#)

### Control Flags

Use the control flag constants to control UDA objects with the [UDAControl\(\)](#) macro.

| Constant                      | Value | Description                                                                      |
|-------------------------------|-------|----------------------------------------------------------------------------------|
| <code>kUDAREinitialize</code> | 1     | Used with the <a href="#">UDAControl()</a> macro to reinitialize the UDA object. |

### Error Constants

At the time of this writing, there is only one error constant associated with the UDA object API.

## Unified Data Access Manager

### Object Option Flags

---

| Constant      | Description                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------|
| udaErrControl | Returned by the <a href="#">UDAControl()</a> macro when the control parameter is not valid for the UDA object. |

### Object Option Flags

You use the object option flag constants to determine information about the internal state of UDA objects. Note that the [UDAEndOfReader\(\)](#) and [UDAMoreData\(\)](#) macros provide you with a convenient means of accessing this same information.

| Constant        | Value | Description                                                                       |
|-----------------|-------|-----------------------------------------------------------------------------------|
| kUDAEndOfReader | 1     | Indicates that the UDA reader has reached the end of its data.                    |
| kUDAMoreData    | 2     | Indicates that the UDA reader needs more space in the read buffer to do its work. |

### Miscellaneous Constants

| Constant                 | Value  | Description                                                                                                                     |
|--------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------|
| kUDAZeroTerminatedBuffer | 0xFFFF | Indicates that the buffer is a null-terminated string. Use this value when creating or reinitializing a UDAMemoryReader object. |

## UDA Manager Functions

### UDAControl Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Applies controls to a UDA object.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | UDAMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | Err UDAControl (UDAObjectType* ioObjectP,<br>UInt16 parameter, va_args)                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>ioObjectP</i><br/>A pointer to the <a href="#">UDAObjectType</a> object that you want to control. This can be a <a href="#">UDAREaderType</a>, a <a href="#">UDAFilterType</a>, or a <a href="#">UDAWriterType</a> object.</p> <p>→ <i>parameter</i><br/>The control action that you want applied to the object.</p> <p>→ <i>va_args</i><br/>Additional parameters, as required for the control and object type.</p> |
| <b>Returns</b>     | Returns <code>errNone</code> if no error, or <code>udaErrorClass</code> if the control parameter is not valid for the <code>ioObjectP</code> .                                                                                                                                                                                                                                                                               |
| <b>Comments</b>    | <p>The UDAControl function applies a control action to a UDA object. You may need to supply additional parameters, depending on the object type and control parameter values.</p> <p>The only control action defined in Palm OS 4.0 is <code>kUDAREinitialize</code>. You can use it as shown in <a href="#">Table 86.1</a>.</p>                                                                                             |

**Table 86.1 UDAControl actions**

| Object Type           | Usage                                     | Action       |
|-----------------------|-------------------------------------------|--------------|
| UDAExchangeReaderType | UDAControl(myExgRdr,<br>kUDAREinitialize) | Does nothing |

## Unified Data Access Manager

### UDADelete

---

**Table 86.1 UDAControl actions (*continued*)**

| Object Type           | Usage                                                       | Action                                                                                                                             |
|-----------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| UDAExchangeWriterType | UDAControl(myExgWtr, kUDAREinitialize)                      | Does nothing                                                                                                                       |
| UDAMemoryReaderType   | UDAControl(myMemRdr, kUDAREinitialize, bufferP, bufferSize) | Reinstalls a new buffer for the memory reader. See <a href="#">UDAMemoryReaderNew()</a> for more information about the parameters. |

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDADelete Macro

**Purpose** Deletes a UDA object.

**Declared In** UDAMgr.h

**Prototype** #define UDADelete (ioObjectP)

**Parameters** → *ioObjectP*  
A pointer to the [UDAObjectType](#) object that you want to delete. This can be a [UDAREaderType](#), a [UDAFilterType](#), or a [UDAWriterType](#) object.

**Returns** Returns nothing.

**Comments** The *ioObjectP* pointer is not valid after this macro completes.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDAEndOfReader Macro

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Tests if the end of the reader has been reached.                                                         |
| <b>Declared In</b>   | UDAMgr.h                                                                                                 |
| <b>Prototype</b>     | <pre>#define UDAEndOfReader (ioReaderP)</pre>                                                            |
| <b>Parameters</b>    | <p>→ <i>ioReaderP</i><br/>A pointer to a <a href="#">UDARedReaderType</a> object.</p>                    |
| <b>Returns</b>       | Returns true if the end of the reader referenced by <i>ioReaderP</i> has been reached, and false if not. |
| <b>Comments</b>      | The end of the reader has been reached.                                                                  |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                      |

## UDAFilterJoin Macro

|                      |                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Joins a filter with a reader.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <pre>#define UDAFilterJoin (ioFilterP, newReaderP)</pre>                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | <p>→ <i>ioFilterP</i><br/>A pointer to a <a href="#">UDAFilterType</a> object.</p> <p>→ <i>newReaderP</i><br/>A pointer to the <a href="#">UDARedReaderType</a> object with which you want the filter joined.</p>                                                                                                                                                                                           |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>      | Each <a href="#">UDAFilterType</a> object receives its data from the <a href="#">UDARedReaderType</a> object to which it is joined; this relationship is established when you create the filter object. You can use this macro to change the reader with which the filter is joined. Upon completion, the filter referenced by <i>ioFilterP</i> is joined with the reader referenced by <i>newReaderP</i> . |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                         |

## UDAINitiateWrite Macro

|                      |                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Causes the <a href="#">UDAWriterType</a> object to read data and then write that data to output.                                                                                              |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                                                                                      |
| <b>Prototype</b>     | <pre>#define UDAINitiateWrite (ioWriterP)</pre>                                                                                                                                               |
| <b>Parameters</b>    | <pre>→ ioWriterP</pre> <p>A pointer to a <a href="#">UDAWriterType</a> object.</p>                                                                                                            |
| <b>Returns</b>       | Returns <code>errNone</code> if successful, and an error code if not.                                                                                                                         |
| <b>Comments</b>      | When you use this macro, the <code>ioWriterP</code> reads data from the reader to which it is joined. It reads data until the reader is empty, and then writes the data to the output medium. |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                           |

## UDAMoreData Macro

|                      |                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Tests if there is more data available to read, but not enough room in the buffer to read it in.                                                                         |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                                                                |
| <b>Prototype</b>     | <pre>#define UDAMoreData (ioReaderP)</pre>                                                                                                                              |
| <b>Parameters</b>    | <pre>→ ioReaderP</pre> <p>A pointer to a <a href="#">UDAREaderType</a> object.</p>                                                                                      |
| <b>Returns</b>       | Returns <code>true</code> if there is more data available for the reader and <code>false</code> if there is no more data available.                                     |
| <b>Comments</b>      | You can use this macro with <a href="#">UDAREaderType</a> objects to determine if there is more data waiting to read. This can happen when the reader's buffer is full. |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                     |

## UDARead Macro

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Uses the specified <a href="#">UDAREaderType</a> object to read data from the input source and place that data into the specified buffer.                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | <pre>#define UDARead (ioReaderP, bufferToFillP,<br/>                bufferSize, errorP)</pre>                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>    | <p>→ <i>ioReaderP</i><br/>A pointer to a <a href="#">UDAREaderType</a> object that performs the read.</p> <p>→ <i>bufferToFillP</i><br/>A pointer to the buffer into which data is placed.</p> <p>→ <i>bufferSize</i><br/>The size of the buffer, in bytes.</p> <p>→ <i>errorP</i><br/>A pointer to an Err value that represents the result of the read operation; if the operation is successful, the value is set to errNone.</p> |
| <b>Returns</b>       | Returns the number of bytes that were actually read. This value can be less than or equal to the value of <i>bufferSize</i> .                                                                                                                                                                                                                                                                                                       |
| <b>Comments</b>      | The reader reads from the input source associated with the reader object and places the data into the specified buffer, reading no more than <i>bufferSize</i> bytes of data.                                                                                                                                                                                                                                                       |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                 |

## UDAWriterFlush Macro

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Flushes the buffer used by the <a href="#">UDAWriterType</a> object.                |
| <b>Declared In</b> | UDAMgr.h                                                                            |
| <b>Prototype</b>   | <pre>#define UDAWriterFlush (ioWriterP)</pre>                                       |
| <b>Parameters</b>  | <p>→ <i>ioWriterP</i><br/>A pointer to a <a href="#">_UDAWriterType</a> object.</p> |
| <b>Returns</b>     | Returns errNone if successful, and an error code if not.                            |

## Unified Data Access Manager

### *UDAWriterJoin*

---

- Comments** You can use this macro to flush any data remaining in the buffer of the writer object referenced by `ioWriterP`. This causes any data in the buffer to be sent to the output medium.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### UDAWriterJoin Macro

- Purpose** Joins a writer object to a different reader object.
- Declared In** `UDAMgr.h`
- Prototype** `#define UDAWriterJoin (ioWriterP, newReaderP)`
- Parameters**
- `→ ioWriterP`  
A pointer to a [UDAWriterType](#) object.
  - `→ newReaderP`  
A pointer to the [UDAREaderType](#) object with which you want the writer joined.
- Returns** Returns nothing.
- Comments** Each [UDAWriterType](#) object receives its data from the [UDAREaderType](#) object to which it is joined; this relationship is established when you create the writer object. You can use this macro to change the reader with which the writer is joined. Upon completion, the writer referenced by `ioWriterP` is joined with the reader referenced by `newReaderP`.
- Compatibility** Implemented only if 4.0 Feature Set is present.

## UDA Object Creation Functions

### UDAExchangeReaderNew Function

|                      |                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Creates a new <a href="#">UDAREaderType</a> object that you can use to read data from an Exchange Manager socket.        |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                 |
| <b>Prototype</b>     | <pre>UDAREaderType* UDAExchangeReaderNew<br/>    (ExgSocketPtr socket)</pre>                                             |
| <b>Parameters</b>    | <p>→ <i>socket</i></p> <p>A pointer to an <a href="#">ExgSocketType</a> structure that describes the connection.</p>     |
| <b>Returns</b>       | Returns a pointer to the newly created <a href="#">UDAREaderType</a> object, or NULL if the reader could not be created. |
| <b>Comments</b>      | Use this function to create a UDA Reader object that takes input from an Exchange Manager socket.                        |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                      |
| <b>See Also</b>      | <a href="#">ExgSocketType</a>                                                                                            |

### UDAExchangeWriterNew Function

|                    |                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Creates a new <a href="#">UDAWriterType</a> object that you can use to write data to an Exchange Manager socket.                                                                                                    |
| <b>Declared In</b> | UDAMgr.h                                                                                                                                                                                                            |
| <b>Prototype</b>   | <pre>UDAWriterType* UDAExchangeWriterNew<br/>    (ExgSocketPtr socket,<br/>     UDABufferSize bufferSize)</pre>                                                                                                     |
| <b>Parameters</b>  | <p>→ <i>socket</i></p> <p>A pointer to an <a href="#">ExgSocketType</a> structure that describes the connection.</p> <p>→ <i>bufferSize</i></p> <p>The size, in bytes, of the buffer for the new writer object.</p> |
| <b>Returns</b>     | Returns a pointer to the newly created UDA Writer, or NULL if the writer could not be created.                                                                                                                      |

## Unified Data Access Manager

### *UDAMemoryReaderNew*

---

- Comments** Use this function to create a UDA Writer object that sends output to an Exchange Manager socket.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [ExgSocketType](#)

## UDAMemoryReaderNew Function

- Purpose** Creates a new [UDAREaderType](#) object that you can use to read data from a memory buffer.
- Declared In** UDAMgr.h
- Prototype**  

```
UDAREaderType* UDAMemoryReaderNew  
    (const UInt8* bufferP,  
     UDABufferSize bufferSizeInBytes)
```
- Parameters**
- *bufferP*  
A pointer to a buffer in memory from which data is read.
  - *bufferSize*  
The size of the buffer, in bytes. If this value is equal to `kUDAZeroTerminatedBuffer`, *bufferP* must point to a null-terminated string buffer.
- Returns** Returns a pointer to the newly created [UDAREaderType](#) object, or NULL if the reader could not be created.
- Comments** Use this function to create a reader that takes input from memory.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

# Compatibility Guide

---

This appendix lists groups of functions and other features (such as events and launch codes) that have been added to the Palm OS® after version 1.0.

Before you use any new functions or features in an application, you must check to ensure that they are implemented in the OS version your application is running on. Checking the OS version number is **not** a reliable indicator that a specific feature is present, since some later OS versions do not include features present in earlier versions. In order to ensure that your code is supported, you must check for the presence of individual features.

To make this check easier, this appendix lists new functions and features in groups such that all functions and features in a group are always implemented together in the ROM of a Palm™ device. This means that you can check for a single feature in that group and be assured that if that feature is present then all functions and features in that group are implemented.

Each group includes a recommended test to check if it is implemented. The following groups are described:

- [2.0 New Feature Set](#)
- [3.0 New Feature Set](#)
- [3.1 New Feature Set](#)
- [3.2 New Feature Set](#)
- [International Feature Set](#)
- [Japanese Feature Set](#)
- [Wireless Internet Feature Set](#)
- [New Serial Manager Feature Set](#)
- [Connection Manager Feature Set](#)
- [3.5 New Feature Set](#)
- [Notification Feature Set](#)

## Compatibility Guide

### 2.0 New Feature Set

---

- [4.0 New Feature Set](#)
- [Expansion Manager Feature Set](#)
- [VFS Manager Feature Set](#)
- [Bluetooth Library Feature Set](#)
- [High-Density Display Feature Set](#)
- [1.5x Display Feature Set](#)
- [Sound Stream Feature Set](#)
- [5.0 New Feature Set](#)
- [5.1 New Feature Set](#)
- [Graffiti 2 Feature Set](#)
- [5.3SC New Feature Set](#)

## 2.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 2.0 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romversion);
```

---

The `romversion` parameter should be 0x02003000 or greater.

### Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdLookup](#)  
[sysAppLaunchCmdPanelCalledFromApp](#)  
[sysAppLaunchCmdReturnFromPanel](#)  
[sysAppLaunchCmdSystemLock](#)

### Functions

This feature set adds the following functions:

|                                                          |                                                      |
|----------------------------------------------------------|------------------------------------------------------|
| <a href="#"><u>CategoryInitialize()</u></a>              | <a href="#"><u>CategorySetName()</u></a>             |
| <a href="#"><u>DmDeleteCategory()</u></a>                | <a href="#"><u>DmDatabaseProtect()</u></a>           |
| <a href="#"><u>EvtAddUniqueEventToQueue()</u></a>        | <a href="#"><u>EvtEventAvail()</u></a>               |
| <a href="#"><u>EvtSysEventAvail()</u></a>                |                                                      |
| <a href="#"><u>FldGetNumberOfBlankLines()</u></a>        | <a href="#"><u>FldGetScrollValues()</u></a>          |
| <a href="#"><u>FldSetInsertionPoint()</u></a>            |                                                      |
| <a href="#"><u>FntGetScrollValues()</u></a>              | <a href="#"><u>FntWordWrap()</u></a>                 |
| <a href="#"><u>FntWordWrapReverseNLines()</u></a>        |                                                      |
| <a href="#"><u>FrmPointInTitle()</u></a>                 | <a href="#"><u>FrmSetMenu()</u></a>                  |
| <a href="#"><u>FrmSetObjectBounds()</u></a>              |                                                      |
| <a href="#"><u>KeySetMask()</u></a>                      | <a href="#"><u>LocGetNumberSeparator<br/>s()</u></a> |
| <a href="#"><u>LstScrollList()</u></a>                   | <a href="#"><u>LstGetVisibleItems()</u></a>          |
| <a href="#"><u>MemCmp()</u></a>                          | <a href="#"><u>MenuSetActiveMenuRscID()</u></a>      |
| <a href="#"><u>PhoneNumberLookup()</u></a>               |                                                      |
| <a href="#"><u>PrefSetPreference()</u></a>               | <a href="#"><u>PrefGetPreference()</u></a>           |
| <a href="#"><u>SclDrawScrollBar()</u></a>                | <a href="#"><u>SclGetScrollBar()</u></a>             |
| <a href="#"><u>SclHandleEvent()</u></a>                  | <a href="#"><u>SclSetScrollBar()</u></a>             |
| <a href="#"><u>SerControl()</u></a>                      |                                                      |
| <a href="#"><u>StrDelocalizeNumber()</u></a>             | <a href="#"><u>StrLocalizeNumber()</u></a>           |
| <a href="#"><u>StrNCaselessCompare()</u></a>             | <a href="#"><u>StrNCat()</u></a>                     |
| <a href="#"><u>StrNCompare()</u></a>                     | <a href="#"><u>StrNCopy()</u></a>                    |
| <a href="#"><u>StrPrintf()</u></a>                       | <a href="#"><u>StrVPrintf()</u></a>                  |
| <a href="#"><u>SysBinarySearch()</u></a>                 | <a href="#"><u>SysCreateDataBaseList<br/>( )</u></a> |
| <a href="#"><u>SysCreatePanelList()</u></a>              | <a href="#"><u>SysErrString()</u></a>                |
| <a href="#"><u>SysGraffitiReferenceDialog(<br/>)</u></a> | <a href="#"><u>SysLibLoad()</u></a>                  |
| <a href="#"><u>SysStringByIndex()</u></a>                | <a href="#"><u>SysTicksPerSecond()</u></a>           |

## Compatibility Guide

### 2.0 New Feature Set

---

[TblHasScrollBar\(\)](#)                      [TblSetBounds\(\)](#)  
[TblSetColumnEditIndicator\(\)](#)   [TblSetRowStaticHeight\(\)](#)

[WinSetWindowBounds](#)

## Existing Functions that Changed

Several functions that existed in 1.0 were changed in 2.0:

[CategoryCreateList\(\)](#) (old function renamed  
[CategoryCreateListV10\(\)](#))

[CategoryEdit\(\)](#) (old function renamed [CategoryEditV10\(\)](#))

[CategoryFreeList\(\)](#) (old function renamed  
[CategoryFreeListV10\(\)](#))

[CategorySelect\(\)](#) (old function renamed  
[CategorySelectV10\(\)](#))

[SelectDay\(\)](#) (old function renamed [SelectDayV10\(\)](#))

[DmFindSortPosition\(\)](#) (old function renamed  
[DmFindSortPositionV10\(\)](#))

[PrefGetAppPreferences\(\)](#) (old function renamed  
[PrefGetAppPreferencesV10\(\)](#))

[PrefOpenPreferenceDB](#) (old function renamed  
[PrefOpenPreferenceDBV10\(\)](#))

[PrefSetAppPreferences\(\)](#) (old function renamed  
[PrefSetAppPreferencesV10\(\)](#))

[SerReceive\(\)](#) (old function renamed [SerReceive10\(\)](#))

[SerSend\(\)](#) (old function renamed [SerSend10\(\)](#))

[SysKeyboardDialog\(\)](#) (old function renamed  
[SysKeyboardDialogV10\(\)](#))

## Other Changes

As a rule, all Palm OS applications developed with the 1.0 SDK should run error-free on the latest device. There are two possible pitfalls for 1.0 applications:

- **fldChangedEvent Change**—The operating system now correctly sends a `fldChangedEvent` whenever a field object is changed. Previously, the event was at times not sent, especially when a `FldSetText` operation was performed. If your application doesn't catch the events that are now sent, it may have problems.
- **Non-standard tools**—If your application was not developed with Metrowerks Code Warrior for the Palm OS, it may run into problems. One known problem can occur if the application:
  - was compiled with optimization turned on
  - uses system preferences

## 3.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.0 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to `0x03003000`, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(3,0,0,sysROMStageRelease,0)
```

---

## Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdExgAskUser](#)  
[sysAppLaunchCmdExgReceiveData](#)

## Compatibility Guide

### 3.0 New Feature Set

---

In addition, the launch code [sysAppLaunchCmdGoto](#) is now also sent by the exchange manager, in addition to its use by the global find operation.

## Font

This feature set adds the following font:

`largeBoldFont`

## Functions

This feature set adds the following functions:

### Dynamic User Interface Functions

|                                      |                                     |
|--------------------------------------|-------------------------------------|
| <a href="#">CtlNewControl()</a>      | <a href="#">FrmNewLabel()</a>       |
| <a href="#">CtlValidatePointer()</a> | <a href="#">FrmRemoveObject()</a>   |
| <a href="#">FldNewField()</a>        | <a href="#">FrmValidatePtr()</a>    |
| <a href="#">FrmNewBitmap()</a>       | <a href="#">LstNewList()</a>        |
| <a href="#">FrmNewForm()</a>         | <a href="#">WinValidateHandle()</a> |
| <a href="#">FrmNewGadget()</a>       |                                     |

For more information on creating and using dynamic user interface elements, see the section “[Dynamic UI](#)” on page 147 of the *Palm OS Programmer’s Companion*, vol. I.

### Font Functions

[FontSelect\(\)](#)  
[FntDefineFont\(\)](#)

For more information on these functions and the support for custom fonts, see “[Fonts](#)” on page 272 of the *Palm OS Programmer’s Companion*, vol. I.

### Progress Manager Functions

|                                  |                                   |
|----------------------------------|-----------------------------------|
| <a href="#">PrgHandleEvent()</a> | <a href="#">PrgUpdateDialog()</a> |
| <a href="#">PrgStartDialog()</a> | <a href="#">PrgUserCancel()</a>   |
| <a href="#">PrgStopDialog()</a>  |                                   |

For more information, see the section “[Progress Dialogs](#)” on page 91 of the *Palm OS Programmer’s Companion*, vol. I.

## **File Streaming Functions**

|                                           |                                       |
|-------------------------------------------|---------------------------------------|
| <a href="#"><u>FileClearerr()</u></a>     | <a href="#"><u>FileOpen()</u></a>     |

| <a href="#"><u>IrIAS_GetType()</u></a>              | <a href="#"><u>IrSetDeviceInfo()</u></a>           |
| <a href="#"><u>IrIAS_GetUserString()</u></a>        | <a href="#"><u>IrTestReq()</u></a>                 |
| <a href="#"><u>IrIAS_GetUserStringCharSet()</u></a> | <a href="#"><u>IrUnbind()</u></a>                  |
| <a href="#"><u>()</u></a>                           |                                                    |

For more information, see the chapter [Beaming \(Infrared Communication\)](#) in the *Palm OS Programmer's Companion*, vol. II, *Communications*.

#### Miscellaneous Functions

|                                                        |                                          |
|--------------------------------------------------------|------------------------------------------|
| <a href="#"><u>FrmRestoreActiveState()</u></a>         | <a href="#"><u>SysGetROMToken()</u></a>  |
| <a href="#"><u>FrmSaveActiveState()</u></a>            | <a href="#"><u>SysGetStackInfo()</u></a> |
| <a href="#"><u>ScrDisplayMode</u></a>                  | <a href="#"><u>SysGremlins()</u></a>     |
| <a href="#"><u>SysGetAppInfo</u></a> (system use only) | <a href="#"><u>TblGetItemFont()</u></a>  |
| <a href="#"><u>SysGetOSVersionString()</u></a>         | <a href="#"><u>TblSetItemFont()</u></a>  |

#### Existing Functions that Changed

Two functions that existed in 2.0 were changed in 3.0:

[CategoryEdit\(\)](#) (old function renamed [CategoryEditV20\(\)](#))

[SysBatteryInfo\(\)](#) (old function renamed [SysBatteryInfoV20\(\)](#))

## Other Changes

- The dynamic heap has been increased in size to 96 KB.
- Storage RAM is no longer subdivided into multiple storage heaps of 64 KB each. All storage RAM on a memory card is configured as a single storage heap.
- Each flash ROM-based Palm device holds a serial number that identifies it uniquely and can be retrieved via [SysGetROMToken\(\)](#). For more information, see “[Retrieving the ROM Serial Number](#)” on page 359 of the *Palm OS Programmer’s Companion*, vol. I.
- The Application Launcher (accessed via the silkscreen “Applications” button) is now an application, rather than a popup. The SysAppLauncherDialog function, which provides the API to the old popup launcher, is still present in Palm OS 3.0 for compatibility purposes, but has not been updated and generally should not be used. For more information, see “[Application Launcher](#)” on page 158 of the *Palm OS Programmer’s Companion*, vol. I.
- The sound manager supports MIDI sound files, adding new sounds, asynchronous playback, and other features. There are also new selectors for setting the volume preferences. For more information, see the section “[System Boot and Reset](#)” on page 344 of the *Palm OS Programmer’s Companion*, vol. I.

The following functions existed in the system previously, but were not documented:

|                                      |                                      |
|--------------------------------------|--------------------------------------|
| <a href="#">RctCopyRectangle()</a>   | <a href="#">RctOffsetRectangle()</a> |
| <a href="#">RctGetIntersection()</a> | <a href="#">RctPtInRectangle()</a>   |
| <a href="#">RctInsetRectangle()</a>  | <a href="#">RctSetRectangle()</a>    |

The following event type existed in the system previously, but was not previously documented:

[frmGotoEvent](#)

## 3.1 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.1 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to `0x03103000`, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(3,1,0,sysROMStageRelease,0)
```

---

## Functions

This feature set adds the following functions:

[ChrHorizEllipsis\(\)](#)  
[ChrNumericSpace\(\)](#)  
`ContrastAdjust`  
[FntWidthToOffset\(\)](#)  
[FtrPtrNew\(\)](#)  
[FtrPtrFree\(\)](#)  
[FtrPtrResize\(\)](#)  
[SelectOneTime\(\)](#)  
[WinDrawChar\(\)](#)  
[WinDrawTruncChars\(\)](#)

---

**NOTE:** The `PalmOSGlue.lib` provides compatibility functions and macros for `ChrHorizEllipsis`, `ChrNumericSpace`, `WinDrawChar`, and `WinDrawTruncChars`. If you want to use these functions on systems that don't have the 3.1 feature set, you can link your application with `PalmOSGlue.lib`. See the chapter "[PalmOSGlue Library](#)" on page 1805 for more information.

---

## Changes to the Character Encoding

Starting in Palm OS 3.1, the character encoding used on most systems is Microsoft Windows code page 1252. Versions prior to 3.1 used an encoding that was very similar to code page 1252 but did not follow it exactly. The following changes to the character set are introduced in Palm OS 3.1:

- Some of the special Palm OS glyphs in the high ASCII range (such as the shortcut stroke and the command stroke) have been moved down into the control code range, and other characters (such as the numeric space and horizontal ellipsis) have been copied into the control range so that they're guaranteed to exist in every encoding. For the numeric space and horizontal ellipsis, you can use the macros [ChrNumericSpace\(\)](#) and [ChrHorizEllipsis\(\)](#) to return the appropriate character regardless of the character map. In `PalmOSGlue.lib`, these two macros are named `TxtGlueGetNumericSpaceChar` and `TxtGlueGetHorizEllipsisChar`, respectively.
- The four playing-card characters have been moved from the high ASCII range in the standard four fonts to the 9-point Symbol font.

## Other Changes in 3.1

- Palm OS 3.1 supports a new processor: the EZ Dragonball processor. This processor is compatible with the existing Dragonball processor, so your application should run without changes as long as it doesn't access registers or system globals directly.

If your application needs to know if it is running on an EZ Dragonball, it can check using the following code:

---

```
DWord id, chip;
Word revision;
Err err;
err = FtrGet(sysFtrCreator,
             sysFtrNumProcessorID, &id);
if (!err) {
    chip = id & sysFtrNumProcessorMask;
    revision = id & 0xffff;
    if (chip==sysFtrNumProcessor328)
        // traditional Dragonball
```

## Compatibility Guide

### 3.1 New Feature Set

---

```
else if (chip==sysFtrNumProcessorEZ)
    // Dragonball EZ
}
```

---

- The constant `preferenceDataVersion` was removed and replaced with `preferenceDataVerLatest`.
- Character variables are now two bytes long. The type `WChar` defines a character variable.
- The `keyDownEvent` structure's `chr` field (which contains the input character) has been changed from a `Word` to a `WChar`.
- The string manager functions [`StrChr\(\)`](#) and [`StrStr\(\)`](#) now treat buffers as characters, not arbitrary byte arrays. If you previously used these functions to search data buffers, your code may no longer work.
- The string manager function [`StrToLower\(\)`](#) can now handle any type of characters, including accented characters.
- The underline attribute of [`FieldAttrType`](#) now has support for the value 2. Previously, the only underline modes available were no underline (0) and gray underline (1). In Palm OS 3.1 and higher, the value 2 is interpreted as solid underline. The `UnderlineModeType` enum defined in `Window.h` defines the possible values for the underline attribute.
- The use of the [`DmGetNextDatabaseByTypeCreator\(\)`](#) `onlyLatestVers` parameter changed in 3.1. If `onlyLatestVers` is true, you only receive one matching database for each type/creator pair. In version 3.0 and earlier, you could receive multiple matching databases if `onlyLatestVers` was true. See that function's description for a more detailed description.

## 3.2 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.2 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumROMVersion,
&romVersion);
```

---

The `romVersion` parameter should be greater than or equal to `0x03203000`, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(3,2,0,sysROMStageRelease,0)
```

---

### Functions

This feature set adds the following functions:

|                                          |                                             |
|------------------------------------------|---------------------------------------------|
| <a href="#">AlmGetProcAlarm()</a>        | <a href="#">NetLibConfigIndexFromName()</a> |
| <a href="#">AlmSetProcAlarm()</a>        | <a href="#">NetLibConfigList()</a>          |
| <a href="#">ClipboardAppendItem()</a>    | <a href="#">NetLibConfigMakeActive()</a>    |
| <a href="#">DmGetDatabaseLockState()</a> | <a href="#">NetLibConfigRename()</a>        |
| <a href="#">ErrAlert()</a>               | <a href="#">NetLibConfigSaveAs()</a>        |
| <a href="#">NetLibConfigAliasGet()</a>   | <a href="#">NetLibOpenConfig()</a>          |
| <a href="#">NetLibConfigAliasSet()</a>   | <a href="#">SndPlaySmfResource()</a>        |
| <a href="#">NetLibConfigDelete()</a>     |                                             |

Note that the `NetLib...` functions, although present in the 3.2 New Feature Set, are first declared in the Palm OS 5 SDK.

### Existing Functions that Changed

Two functions that existed in 3.0 were changed in 3.2:

## Compatibility Guide

### International Feature Set

---

[SysGremlins\(\)](#) was removed and replaced with a `SysGremlins` macro that maps it to the function `HostGremlinIsRunning`. The prototype is slightly different, but you can still call `SysGremlins` in the same way you did before.

[PrgStartDialog\(\)](#) (old function renamed  
[PrgStartDialogV31\(\)](#))

### Other Changes in 3.2

- The prototype for the system use only function `AlmDisplayAlarm` changed from no return value to a Boolean return value. This change may affect system patches and extensions that intercept `AlmDisplayAlarm` calls.

## International Feature Set

You can check that this feature set is implemented by checking for the existence of the international manager. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumIntlMgr, &value);
```

---

If the international manager is installed, the `value` parameter will be non-zero and the returned error should also be zero (for no error).

You can learn more about the international manager by reading the chapter “[Localized Applications](#)” on page 369 in the *Palm OS Programmer’s Companion*, vol. I.

---

**NOTE:** If you want to use international functions on systems that don’t have the international feature, you can link your application with `PalmOSGlue.lib`. The functions in this library are the same as those listed below except that they use the prefix “`TxtGlue`” instead of “`Txt`.” For more information, see the chapter “[PalmOSGlue Library](#)” on page 1805.

---

## Functions

This feature set adds the following functions:

### Text Manager Functions

|                                             |                                                 |
|---------------------------------------------|-------------------------------------------------|
| <a href="#"><u>TxtByteAttr()</u></a>        | <a href="#"><u>TxtCharXAttr()</u></a>           |
| <a href="#"><u>TxtCaselessCompare()</u></a> | <a href="#"><u>TxtCompare()</u></a>             |
| <a href="#"><u>TxtCharAttr()</u></a>        | <a href="#"><u>TxtEncodingName()</u></a>        |
| <a href="#"><u>TxtCharBounds()</u></a>      | <a href="#"><u>TxtFindString()</u></a>          |
| <a href="#"><u>TxtCharEncoding()</u></a>    | <a href="#"><u>TxtGetChar()</u></a>             |
| <a href="#"><u>TxtCharIsAlNum()</u></a>     | <a href="#"><u>TxtGetNextChar()</u></a>         |
| <a href="#"><u>TxtCharIsAlpha()</u></a>     | <a href="#"><u>TxtGetPreviousChar()</u></a>     |
| <a href="#"><u>TxtCharIsCntrl()</u></a>     | <a href="#"><u>TxtCharIsValid()</u></a>         |
| <a href="#"><u>TxtCharIsDigit()</u></a>     | <a href="#"><u>TxtMaxEncoding()</u></a>         |
| <a href="#"><u>TxtCharIsGraph()</u></a>     | <a href="#"><u>TxtNextCharSize()</u></a>        |
| <a href="#"><u>TxtCharIsHardKey()</u></a>   | <a href="#"><u>TxtPreviousCharSize()</u></a>    |
| <a href="#"><u>TxtCharIsHex()</u></a>       | <a href="#"><u>TxtReplaceStr()</u></a>          |
| <a href="#"><u>TxtCharIsLower()</u></a>     | <a href="#"><u>TxtSetNextChar()</u></a>         |
| <a href="#"><u>TxtCharIsPrint()</u></a>     | <a href="#"><u>TxtStrEncoding()</u></a>         |
| <a href="#"><u>TxtCharIsPunct()</u></a>     | <a href="#"><u>TxtTransliterate()</u></a>       |
| <a href="#"><u>TxtCharIsSpace()</u></a>     | <a href="#"><u>TxtGetTruncationOffset()</u></a> |
| <a href="#"><u>TxtCharIsUpper()</u></a>     | <a href="#"><u>TxtWordBounds()</u></a>          |
| <a href="#"><u>TxtCharSize()</u></a>        |                                                 |

### Other Functions

[IntlGetRoutineAddress\(\)](#)

### Removed Functions and Macros

If the international feature set exists, then the following functions and macros are no longer available:

## Compatibility Guide

### *Japanese Feature Set*

---

[GetCharAttr\(\)](#)  
[GetCharCaselessValue\(\)](#)  
[GetCharSortValue\(\)](#)  
IsAscii  
IsAlNum  
IsAlpha  
IsCntrl  
IsDigit  
IsGraph  
IsLower  
IsPrint  
IsPunct  
IsSpace  
IsUpper  
IsHex  
IsDelim

## Japanese Feature Set

You can check that the Japanese feature set is implemented by checking if the unit is Japanese. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumEncoding, &value);
```

---

The unit has the Japanese OS if the value parameter is `charEncodingCP932`.

For further information about the Japanese implementation, see the section “[Notes on the Japanese Implementation](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Wireless Internet Feature Set

You can check that this feature set is implemented by checking for the existence of the Web Clipping Application Viewer (*Viewer*) and iMessenger™ applications. Here's an example of how to check for Viewer:

---

```
DmSearchStateType searchState;
UInt16 cardNo;
LocalID dbID;
err = DmGetNextDatabaseByTypeCreator(true,
&searchState, sysFileTApplication,
sysFileCClipper, true, &cardNo, &dbID);
```

---

If Viewer is not present, the DmGetNextDatabaseByTypeCreator routine returns an error. To check for iMessenger, you can use the creator type sysFileCMessaging.

---

**NOTE:** The Viewer was formerly described as the Clipper.

---

You can learn more about the Palm.Net™ system for wireless Internet access and the programmatic interfaces to the Viewer and iMessenger applications by reading the chapter “[Internet and Messaging Applications](#)” in the *Palm OS Programmer's Companion*, vol. II, *Communications*. For a more complete description, see the *Web Clipping Developer's Guide*.

## Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdAddRecord](#) (for iMessenger application; existed for Mail in 3.0)  
[sysAppLaunchCmdGoToURL](#)  
[sysAppLaunchCmdOpenDB](#)  
[sysAppLaunchCmdURLParams](#)

## Events

This feature set adds the following events:

[inetSockReadyEvent](#)  
[inetSockStatusChangeEvent](#)

This feature set also adds the following keyDownEvent key codes:

vchrHardAntenna  
vchrRadioCoverageOK  
vchrRadioCoverageFail

These key codes are described in the section [Wireless keyDownEvent Key Codes](#).

## Functions

This feature set adds the following functions.

### Internet Library Functions

For more information, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

|                                              |                                           |
|----------------------------------------------|-------------------------------------------|
| <a href="#">INetLibCacheGetObject()</a>      | <a href="#">INetLibSockClose()</a>        |
| <a href="#">INetLibCacheList()</a>           | <a href="#">INetLibSockConnect()</a>      |
| <a href="#">INetLibCheckAntennaState()</a>   | <a href="#">INetLibSockHTTPAttrGet()</a>  |

| <a href="#">INetLibSettingSet()</a>          | <a href="#">INetLibWiCmd()</a>            |

## New Serial Manager Feature Set

The New Serial Manager feature set has two different versions.

### New Serial Manager Feature Set Version 1

You can check that this feature set is implemented by checking for the existence of the new Serial Manager. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFileCSerialMgr,  
sysFtrNewSerialPresent, &value);
```

---

If the new Serial Manager is installed, the value parameter will be non-zero and the returned error should also be zero (for no error).

You can learn more about the new Serial Manager and Connection Manager by reading the sections “[The Serial Manager](#)” on page 92 and “[The Connection Manager](#)” on page 116 in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

This feature set adds the following functions.

#### Serial Manager Functions

|                                         |                                         |
|-----------------------------------------|-----------------------------------------|
| <a href="#">SrmClearErr()</a>           | <a href="#">SrmReceiveFlush()</a>       |
| <a href="#">SrmClose()</a>              | <a href="#">SrmReceiveWait()</a>        |
| <a href="#">SrmControl()</a>            | <a href="#">SrmReceiveWindowClose()</a> |
| <a href="#">SrmGetDeviceCount()</a>     | <a href="#">SrmReceiveWindowOpen()</a>  |
| <a href="#">SrmGetDeviceInfo()</a>      | <a href="#">SrmSend()</a>               |
| <a href="#">SrmGetStatus()</a>          | <a href="#">SrmSendCheck()</a>          |
| <a href="#">SrmOpen()</a>               | <a href="#">SrmSendFlush()</a>          |
| <a href="#">SrmOpenBackground()</a>     | <a href="#">SrmSendWait()</a>           |
| <a href="#">SrmPrimeWakeupHandler()</a> | <a href="#">SrmSetReceiveBuffer()</a>   |
| <a href="#">SrmReceive()</a>            | <a href="#">SrmSetWakeupHandler()</a>   |
| <a href="#">SrmReceiveCheck()</a>       | <a href="#">WakeupHandlerProcPtr()</a>  |

## Compatibility Guide

### New Serial Manager Feature Set

---

#### Virtual Driver Functions

|                                               |                                            |
|-----------------------------------------------|--------------------------------------------|
| <a href="#"><u>DrvEntryPointProcPtr()</u></a> | <a href="#"><u>VdrvStatusProcPtr()</u></a> |
| <a href="#"><u>GetSizeProcPtr()</u></a>       | <a href="#"><u>VdrvWriteProcPtr()</u></a>  |
| <a href="#"><u>GetSpaceProcPtr()</u></a>      | <a href="#"><u>WriteBlockProcPtr()</u></a> |
| <a href="#"><u>VdrvControlProcPtr()</u></a>   | <a href="#"><u>WriteByteProcPtr()</u></a>  |
| <a href="#"><u>VdrvOpenProcPtr()</u></a>      |                                            |

#### Connection Manager Functions

|                                           |                                            |
|-------------------------------------------|--------------------------------------------|
| <a href="#"><u>CncAddProfile()</u></a>    | <a href="#"><u>CncGetProfileInfo()</u></a> |
| <a href="#"><u>CncDeleteProfile()</u></a> | <a href="#"><u>CncGetProfileList()</u></a> |

#### Serial Link Manager Function

[SlkSocketPortID\(\)](#)

## New Serial Manager Feature Set Version 2

You can check that version 2 of the new Serial Manager feature set is implemented by checking the Serial Manager version number and the Palm OS version number. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFileCSerialMgr,
             sysFtrNewSerialVersion, &value);
err = FtrGet(sysFtrCreator,
             sysFtrNumROMVersion, &romVersion);
```

---

The new Serial Manager is present if:

- Both calls to `FtrGet` return zero (for no error).
- The value parameter is 2.
- The `romVersion` parameter is 0x04003000, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(4, 0, 0, sysROMStageRelease, 0)
```

---

This feature set adds the following functions.

### Serial Manager Functions

[SrmCustomControl\(\)](#)      [SrmExtOpen\(\)](#)  
[SrmExtOpenBackground\(\)](#)

### Virtual Driver Functions

[VdrvControlCustomProcPtr](#) [VdrvOpenProcV4Ptr\(\)](#)  
[\(\)](#)  
[SignalCheckPtr\(\)](#)

---

**IMPORTANT:** Some Handspring devices ship with Palm OS version 3.5 but have new Serial Manager feature set version 2. These devices support the `SignalCheckPtr` virtual driver function and have expanded functionality for USB support, but they do not support the other function calls in this feature set.

---

You can learn more about the new Serial Manager by reading the chapter “[Serial Communication](#)” on page 89 of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Connection Manager Feature Set

You can check that the Connection Manager feature set is implemented by checking the value of the Connection Manager feature. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(kCncFtrCncMgrCreator,  
kCncFtrCncMgrVersion, &version);
```

---

The `version` parameter should be greater than or equal to 0x00040001. In the 4.0 Palm OS SDK, this value is represented by the `kCncMgrVersion` constant.

---

**NOTE:** An earlier version of the Connection Manager is available if [New Serial Manager Feature Set Version 1](#) is present.

---

## Functions

This feature set adds the following functions:

|                                                   |                                                  |
|---------------------------------------------------|--------------------------------------------------|
| <a href="#"><u>CncProfileCloseDB()</u></a>        | <a href="#"><u>CncProfileGetIDFromName()</u></a> |
| <a href="#"><u>CncProfileCount()</u></a>          |                                                  |
| <a href="#"><u>CncProfileCreate()</u></a>         | <a href="#"><u>CncProfileGetIndex()</u></a>      |
| <a href="#"><u>CncProfileDelete()</u></a>         | <a href="#"><u>CncProfileOpenDB()</u></a>        |
| <a href="#"><u>CncProfileGetCurrent()</u></a>     | <a href="#"><u>CncProfileSetCurrent()</u></a>    |
| <a href="#"><u>CncProfileGetIDFromIndex()</u></a> | <a href="#"><u>CncProfileSettingGet()</u></a>    |
| <a href="#"><u>()</u></a>                         | <a href="#"><u>CncProfileSettingSet()</u></a>    |

## 3.5 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.5 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to 0x03503000, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(3,5,0,sysROMStageRelease,0)
```

---

## Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdNotify](#)

## Events

This feature set adds the following events:

[frmGadgetEnterEvent](#)  
[frmGadgetMiscEvent](#)  
[menuCmdBarOpenEvent](#)  
[menuOpenEvent](#)

## Functions

This feature set adds the following functions:

### Bitmaps

|                                            |                                            |
|--------------------------------------------|--------------------------------------------|
| <a href="#"><u>BmpBitsSize()</u></a>       | <a href="#"><u>BmpGetBits()</u></a>        |
| <a href="#"><u>BmpColortableSize()</u></a> | <a href="#"><u>BmpGetColortable()</u></a>  |
| <a href="#"><u>BmpCompress()</u></a>       | <a href="#"><u>BmpSize()</u></a>           |
| <a href="#"><u>BmpCreate()</u></a>         | <a href="#"><u>ColorTableEntries()</u></a> |
| <a href="#"><u>BmpDelete()</u></a>         |                                            |

For more information on creating and using bitmaps, see the section “[Bitmaps](#)” on page 129 of the *Palm OS Programmer’s Companion*, vol. I.

### Controls

|                                               |                                             |
|-----------------------------------------------|---------------------------------------------|
| <a href="#"><u>CtlGetSliderValues()</u></a>   | <a href="#"><u>CtlSetGraphics()</u></a>     |
| <a href="#"><u>CtlNewGraphicControl()</u></a> | <a href="#"><u>CtlSetSliderValues()</u></a> |
| <a href="#"><u>CtlNewSliderControl()</u></a>  |                                             |

These functions add support for graphical buttons and slider controls. For more information, see the section “[Offscreen Windows](#)” on page 97 of the *Palm OS Programmer’s Companion*, vol. I.

### Forms

|                                                 |                                              |
|-------------------------------------------------|----------------------------------------------|
| <a href="#"><u>FrmCustomResponseAlert()</u></a> | <a href="#"><u>FrmSetGadgetHandler()</u></a> |
| <a href="#"><u>FrmNewGsi()</u></a>              |                                              |

Among the changes to form functions is extended gadget support. For more information on gadgets and extended gadgets, see the section “[Custom UI Objects \(Gadgets\)](#)” on page 145 of the *Palm OS Programmer’s Companion*, vol. I.

### Menus

|                                            |                                                  |
|--------------------------------------------|--------------------------------------------------|
| <a href="#"><u>MenuAddItem()</u></a>       | <a href="#"><u>MenuCmdBarAddButton()</u></a>     |
| <a href="#"><u>MenuCmdBarDisplay()</u></a> | <a href="#"><u>MenuCmdBarGetButtonData()</u></a> |
| <a href="#"><u>MenuHideItem()</u></a>      | <a href="#"><u>MenuShowItem()</u></a>            |

## Compatibility Guide

### 3.5 New Feature Set

---

For more information on using menu functions, see the section “[Menus](#)” on page 111 of the *Palm OS Programmer’s Companion*, vol. I.

#### Overlay Manager

|                                       |                                           |
|---------------------------------------|-------------------------------------------|
| <a href="#">OmGetCurrentLocale()</a>  | <a href="#">OmLocaleToOverlayDBName()</a> |
| <a href="#">OmGetIndexedLocale()</a>  | <a href="#">)</a>                         |
| <a href="#">OmGetRoutineAddress()</a> | <a href="#">OmOverlayDBNameToLocale()</a> |
| <a href="#">OmGetSystemLocale()</a>   | <a href="#">)</a>                         |
|                                       | <a href="#">OmSetSystemLocale()</a>       |

For more information on using the overlay manager, see the section “[Using Overlays to Localize Resources](#)” on page 371 of the *Palm OS Programmer’s Companion*, vol. I.

#### Private Records

|                                       |                               |
|---------------------------------------|-------------------------------|
| <a href="#">SecSelectViewStatus()</a> | <a href="#">SecVerifyPW()</a> |
|---------------------------------------|-------------------------------|

#### Tables

|                                 |                                      |
|---------------------------------|--------------------------------------|
| <a href="#">TblGetItemPtr()</a> | <a href="#">TblSetColumnMasked()</a> |
| <a href="#">TblRowMasked()</a>  | <a href="#">TblSetRowMasked()</a>    |

#### UI Colors

|                                             |                                        |
|---------------------------------------------|----------------------------------------|
| <a href="#">UIColorGetTableEntryIndex()</a> | <a href="#">UIColorSetTableEntry()</a> |
| <a href="#">UIColorGetTableEntryRGB()</a>   | <a href="#">)</a>                      |

For more information on using the UI Colors API, see the section “[Color and Grayscale Support](#)” on page 149 of the *Palm OS Programmer’s Companion*, vol. I.

#### UI Controls

|                                      |                               |
|--------------------------------------|-------------------------------|
| <a href="#">UIBrightnessAdjust()</a> | <a href="#">UIPickColor()</a> |
|--------------------------------------|-------------------------------|

## Windows

|                                                |                                                 |
|------------------------------------------------|-------------------------------------------------|
| <a href="#"><u>WinCreateBitmapWindow()</u></a> | <a href="#"><u>WinPaintRectangle()</u></a>      |
| <a href="#"><u>WinDrawPixel()</u></a>          | <a href="#"><u>WinPaintRectangleFrame()</u></a> |
| <a href="#"><u>WinErasePixel()</u></a>         | <a href="#"><u>WinPalette()</u></a>             |
| <a href="#"><u>WinGetBitmap()</u></a>          | <a href="#"><u>WinPopDrawState()</u></a>        |
| <a href="#"><u>WinGetPatternType()</u></a>     | <a href="#"><u>WinPushDrawState()</u></a>       |
| <a href="#"><u>WinGetPixel()</u></a>           | <a href="#"><u>WinRGBToIndex()</u></a>          |
| <a href="#"><u>WinIndexToRGB()</u></a>         | <a href="#"><u>WinScreenLock()</u></a>          |
| <a href="#"><u>WinInvertPixel()</u></a>        | <a href="#"><u>WinScreenMode()</u></a>          |
| <a href="#"><u>WinPaintBitmap()</u></a>        | <a href="#"><u>WinScreenUnlock()</u></a>        |
| <a href="#"><u>WinPaintChar()</u></a>          | <a href="#"><u>WinSetBackColor()</u></a>        |
| <a href="#"><u>WinPaintChars()</u></a>         | <a href="#"><u>WinSetDrawMode()</u></a>         |
| <a href="#"><u>WinPaintLine()</u></a>          | <a href="#"><u>WinSetForeColor()</u></a>        |
| <a href="#"><u>WinPaintLines()</u></a>         | <a href="#"><u>WinSetPatternType()</u></a>      |
| <a href="#"><u>WinPaintPixel()</u></a>         | <a href="#"><u>WinSetTextColor()</u></a>        |
| <a href="#"><u>WinPaintPixels()</u></a>        |                                                 |

For more information on using the window functions, see the section “[Drawing on the Palm Powered Handheld](#)” on page 74 of the *Palm OS Programmer’s Companion*, vol. I.

## Miscellaneous New Functions

|                                            |                                          |
|--------------------------------------------|------------------------------------------|
| <a href="#"><u>DmOpenDBNoOverlay()</u></a> | <a href="#"><u>ResLoadConstant()</u></a> |
| <a href="#"><u>ExgDoDialog()</u></a>       | <a href="#"><u>TxtParamString()</u></a>  |
| <a href="#"><u>DateToAscii()</u></a>       |                                          |

## Existing Functions that Changed

The following functions that existed prior to 3.5 have changed in release 3.5:

ScrDisplayMode was changed to [WinScreenMode\(\)](#).

ContrastAdjust was changed to [UIContrastAdjust\(\)](#).

[SelectTime\(\)](#) (old function renamed [SelectTimeV33\(\)](#))

## New Data Types

The data types `Byte`, `Word`, `DWord` and so on are now deprecated. It is recommended that you use the corresponding new data types. For example, use `Int16` instead of `SWord` and `UInt32` instead of `DWord`. In particular, the unfortunate distinction between `Handle`/`VoidHand` has been fixed; use `MemHandle` instead.

To learn in general how the type names changed, see the header file `PalmOSCompatibility.h`. This file provides a mapping from the old type name to the new type name. If you need to move forward without modifying your code, you can include this file in your project to provide declarations for the old type names.

## Changes to Events

- The `tapCount` field has been added to the [EventType](#) structure. The `tapCount` field specifies the number of times the user tapped the pen at the current location; in fields, two taps selects a word, and three taps selects a line.

---

**IMPORTANT:** Because the `tapCount` field has been added to the `EventType` structure, it has become more critical that you clear the event structure before using it to add a new event to the queue. Otherwise, the `tapCount` will be incorrect for the new event.

---

- The structures for [ctlRepeatEvent](#) and [ctlSelectEvent](#) have a `value` field added to them. This new field is used only for sliders; it holds the current value of the slider.
- Form objects now handle the [frmTitleSelectEvent](#) by adding a [keyDownEvent](#) with the `vchrMenu` character to the event queue (which causes the form's menu to display).
- Some of the structure definitions for system-level events have moved from `Event.h` to `SysEvent.h`.
- The [winEnterEvent](#) is now not generated until [FrmDrawForm\(\)](#) is called. Make sure to draw your form in response to [frmOpenEvent](#), not `winEnterEvent`.
- [EvtSetNullEventTick\(\)](#) is now a function. In previous releases it was a macro.

## Other Changes

- [FrmDrawForm\(\)](#)

On release 3.5, FrmDrawForm erases the window's rectangle before it draws, so you must perform custom drawing after the call to FrmDrawForm, not before. If you have drawn before the call to FrmDrawForm, your changes are lost. On debug ROMs, the window handle is invalid until FrmDrawForm is called so that draws before FrmDrawForm result in a bus error.

- Resource Manager

The resource manager functions have been updated to work with overlay databases. See “[Using Overlays to Localize Resources](#)” on page 371 of the *Palm OS Programmer's Companion*, vol. I.

- [DmGetDatabase\(\)](#)

The order in which this call returns databases has changed. Previously all of the databases from ROM were returned first, then all from RAM. Now they are intermingled. Developers should not rely on the order in which databases are returned from this call.

- [StrToLower\(\)](#)

This function is different in 3.5 Latin ROMs. Previously it only changed A through Z. Now it also changes high ASCII characters.

- [Time Manager](#)

If you are using a debug ROM, the string buffer is filled with dateStringLength or longStrLength debugging bytes, depending on the dateFormat parameter. For the routines that return the day-of-week name in addition to the date, the size of the buffers has been expanded, so developers need to check the max lengths defined in `DateTime.h`.

- The format of the storage heap header has changed, thus any existing saved Simulator card images are invalid and should be tossed.

## Compatibility Guide

### Notification Feature Set

---

- [Category Data Structures](#)

The data structure [AppInfoType](#) has been documented.

[CategoryCreateList\(\)](#) now has a “hide” function with two new constants; `categoryHideEditCategory`, and `categoryDefaultEditCategoryString`.

- [FtrPtrNew\(\)](#)

`FtrPtrNew` now allows allocating chunks larger than 64KB.

- Dynamic heap

The dynamic heap is now sized based on the amount of memory available to the system.

**Table B.1 Dynamic heap size**

| Device RAM Size                  | Heap Size |
|----------------------------------|-----------|
| $x < 2\text{MB}$                 | 64KB      |
| $2\text{MB} \leq x < 4\text{MB}$ | 128KB     |
| $x \geq 4\text{MB}$              | 256KB     |

## Notification Feature Set

You can check that this feature set is implemented by checking for the existence of the notification manager. You can check by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumNotifyMgrVersion, &value);
```

---

If the notification manager is part of the system, the `value` parameter will be non-zero and the returned error should also be zero (for no error).

### Notification Manager

[SysNotifyBroadcast\(\)](#)                      [SysNotifyRegister\(\)](#)  
[SysNotifyBroadcastDeferred\(\)](#)   [SysNotifyUnregister\(\)](#)  
[\)](#)

To learn more about the notification manager, see the section [“Notifications”](#) on page 30 of the *Palm OS Programmer’s Companion*, vol. I.

## 4.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 4.0 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to 0x04003000, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(4,0,0,sysROMStageRelease,0)
```

---

### Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdAttention](#)

[sysAppLaunchCmdExgGetData](#)

[sysAppLaunchCmdExgPreview](#)

### Notifications

This feature set adds the following notifications:

## Compatibility Guide

### 4.0 New Feature Set

---

[cncNotifyProfileEvent](#)  
[sysExternalConnectorAttachEvent](#)  
[sysExternalConnectorDetachEvent](#)  
[sysNotifyCardInsertedEvent](#)  
[sysNotifyCardRemovedEvent](#)  
[sysNotifyDBDeletedEvent](#)  
[sysNotifyDeleteProtectedEvent](#)  
[sysNotifyDeviceUnlocked](#)

|                                                      | <a href="#"><u>TelStyGetAuthenticationState()</u></a>   |

For more information about the Telephony Manager, see [Chapter 10](#), “[Telephony Manager](#),” in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

### Windows Manager

|                                             |                                             |
|---------------------------------------------|---------------------------------------------|
| <a href="#"><u>WinGetPixelRGB()</u></a>     | <a href="#"><u>WinSetBackColorRGB()</u></a> |
| <a href="#"><u>WinSetForeColorRGB()</u></a> | <a href="#"><u>WinSetTextColorRGB()</u></a> |

### Internationalization Functions

The following functions have been added to aid with creating localized applications:

|                                                |                                                |
|------------------------------------------------|------------------------------------------------|
| <a href="#"><u>FntWCharWidth()</u></a>         | <a href="#"><u>OmGetNextSystemLocale()</u></a> |
| <a href="#"><u>StrCompareAscii()</u></a>       | <a href="#"><u>TxtConvertEncoding()</u></a>    |
| <a href="#"><u>TxtGetWordWrapOffset()</u></a>  | <a href="#"><u>TxtNameToEncoding()</u></a>     |
| <a href="#"><u>IntlSetRoutineAddress()</u></a> |                                                |

## Existing Functions that Changed

The following functions that existed prior to 4.0 have changed in release 4.0:

[ExgRegisterData\(\)](#) has been deprecated. The preferred function is now [ExgRegisterDatatype\(\)](#).

[ExgGet\(\)](#) was previously unimplemented. It has been implemented in release 4.0

[ExgNotifyReceive\(\)](#) was previously a private function. It is now a public function, intended to be used by exchange libraries.

[FldRecalculateField\(\)](#) now updates the word-wrapping information whenever `FldRecalculateField` is called, regardless of the value of the `redraw` parameter. Prior to Palm OS 4.0 it updated the word-wrapping information only if the `redraw` parameter was set to `true`.

[StrNCaselessCompare\(\)](#) now requires both of its string parameters to be null-terminated.

[StrNCompare\(\)](#) now requires both of its string parameters to be null-terminated.

## Expansion Manager Feature Set

Because not every system has (or needs) Expansion Manager services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the Expansion Manager's system feature with a call to [FtrGet\(\)](#), supplying `sysFileCExpansionMgr` for the feature creator and `expFtrIDVersion` for the feature number.

## Compatibility Guide

### *Expansion Manager Feature Set*

---

The following code shows how to check for the presence and proper version of the Expansion Manager. Note that `expectedExpMgrVersionNum` should be replaced by the actual version number you expect.

---

```
UInt32 expMgrVersion;
Err err;

err = FtrGet(sysFileCExpansionMgr,
    expFtrIDVersion, &expMgrVersion);
if(err){
    // Expansion Manager not installed
} else {
    // check version number of Expansion Manager,
    // if necessary
    if(expMgrVersion == expectedExpMgrVersionNum)
        // everything is OK
}
```

---

You can learn more about the expansion manager by reading [Chapter 29, “Expansion Manager,”](#) on page 615.

## Functions

This feature set adds the following functions.

### Expansion Manager Functions

|                                        |                                       |
|----------------------------------------|---------------------------------------|
| <a href="#">ExpCardGetSerialPort()</a> | <a href="#">ExpSlotDriverRemove()</a> |
| <a href="#">ExpCardInfo()</a>          | <a href="#">ExpSlotEnumerate()</a>    |
| <a href="#">ExpCardPresent()</a>       | <a href="#">ExpSlotLibFind()</a>      |
| <a href="#">ExpSlotDriverInstall()</a> |                                       |

## VFS Manager Feature Set

Because not every system has (or needs) Virtual File System (VFS) Manager services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the VFS Manager’s system feature with a call to [FtrGet\(\)](#), supplying `sysFileCVFSMgr` for the feature creator and `vfsFtrIDVersion` for the feature number.

The following code shows how to check for the presence and proper version of the VFS Manager. Note that `expectedVFSMgrVersionNum` should be replaced by the actual version number you expect.

## Compatibility Guide

### VFS Manager Feature Set

---

---

```
UInt32 vfsMgrVersion;
Err err;

err = FtrGet(sysFileCVFSMgr,
    vfsFtrIDVersion, &vfsMgrVersion);
if(err){
    // VFS Manager not installed
} else {
    // check version number of VFS Manager,
    // if necessary
    if(vfsMgrVersion == expectedVFSMgrVersionNum)
        // everything is OK
}
```

---

You can learn more about the VFS manager by reading [Chapter 53](#), “[Virtual File System Manager](#),” on page 1037.

## Functions

This feature set adds the following functions.

### VFS Manager Functions

| <a href="#"><u>VFSFileSetDate()</u></a>       |                                                        |
| <a href="#"><u>VFSFileSeek()</u></a>          |                                                        |

## Bluetooth Library Feature Set

Because not every system has (or needs) Bluetooth Library services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the Bluetooth Library's system feature with a call to [FtrGet\(\)](#), supplying `btLibFeatureCreator` for the feature creator and `btLibFeatureVersion` for the feature number.

The following code shows how to check for the presence of the Bluetooth Library.

---

```
UInt32 btVersion;

// Make sure Bluetooth components are installed
// This check also ensures Palm OS 4.0 or greater
if (FtrGet(btLibFeatureCreator, btLibFeatureVersion,
    &btVersion) != errNone) {
    // Alert the user if it's the active application
```

```
if ((launchFlags & sysAppLaunchFlagNewGlobals) &&
    (launchFlags & sysAppLaunchFlagUIApp))
    FrmAlert (MissingBtComponentsAlert);
return sysErrRomIncompatible;
}
```

---

You can learn more about the Bluetooth Library by reading [Chapter 6, “Bluetooth,”](#) on page 129 of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Functions

This feature set adds the following functions.

### Bluetooth Library Security Functions

[BtLibSecurityFindTrustedDeviceRecord\(\)](#)      [BtLibSecurityNumTrustedDeviceRecords\(\)](#)

[BtLibSecurityGetTrustedDeviceRecordInfo\(\)](#)      [BtLibSecurityRemoveTrustedDeviceRecord\(\)](#)

### Bluetooth Library Utility Functions and Macros

[BtLibAddrAToBtd\(\)](#)      [BtLibRfCommHToNS\(\)](#)

[BtLibAddrBtdToA\(\)](#)      [BtLibRfCommNToHL\(\)](#)

[BtLibL2CapHToNL\(\)](#)      [BtLibRfCommNToHS\(\)](#)

[BtLibL2CapHToNS\(\)](#)      [BtLibSdpHToNL\(\)](#)

[BtLibL2CapNToHL\(\)](#)      [BtLibSdpHToNS\(\)](#)

[BtLibL2CapNToHS\(\)](#)      [BtLibSdpNToHL\(\)](#)

[BtLibRfCommHToNL\(\)](#)      [BtLibSdpNToHS\(\)](#)

### Bluetooth Library Management Functions

[BtLibClose\(\)](#)      [BtLibLinkSetState\(\)](#)

[BtLibOpen\(\)](#)      [BtLibPiconetCreate\(\)](#)

[BtLibCancelInquiry\(\)](#)      [BtLibPiconetDestroy\(\)](#)

|                                                       |                                                                |
|-------------------------------------------------------|----------------------------------------------------------------|

## High-Density Display Feature Set

You can verify that this feature set is implemented by checking the version of the Window Manager. If the Window Manager version is 4 or greater, the High-Density Display feature set is supported. To check the version of the Window Manager, use this call:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumWinVersion, &version);
```

---

Upon return, if `version` has a value of 4 or greater, the High-Density Display feature set is present. Note that just because the High-Density Display feature set is present, it isn't necessarily being used. You may want to check the density of the screen, as follows:

---

```
WinScreenGetAttribute(winScreenDensity, &attr);  
if (attr == kDensityDouble) {
```

---

```
//the screen is double density  
}
```

---

The [5.0 New Feature Set](#) incorporates all of the functionality present in the High-Density Display Feature Set, so if your application is running on Palm OS 5 you can assume that the High-Density Display Feature Set is present as well.

## New Data Types

This feature set adds the following new data types.

### Bitmap Data Types

[BitmapTypeV0](#)

[BitmapTypeV1](#)

[BitmapTypeV2](#)

[BitmapTypeV3](#)

[DensityType](#)

[PixelFormatType](#)

In addition, the definition of [BitmapType](#) changed.

### Font Data Types

[FontDensityType](#)

[FontTypeV2](#)

In addition, this feature set defines a new [Extended Font Resource](#).

### Window Constants

This feature set adds a new set of [Window Coordinate System Constants](#).

## Functions

This feature set adds the following functions.

### Bitmap Functions

[BmpCreateBitmapV3\(\)](#)

[BmpGetCompressionType\(\)](#)

[BmpGetDensity\(\)](#)

[BmpGetNextBitmapAnyDensity\(\)](#)

## Compatibility Guide

### 1.5x Display Feature Set

---

[BmpGetTransparentValue\( BmpGetVersion\(\)  
\)](#)

[BmpSetDensity\(\)](#)                      [BmpSetTransparentValue\(\)](#)

#### System Event Manager Functions

[EvtGetPenNative\(\)](#)

#### Window Functions

[WinGetCoordinateSystem\(\)](#)   [WinGetSupportedDensity\(\)](#)

[WinPaintRoundedRectangle](#)   [WinPaintTiledBitmap\(\)  
Frame\(\)](#)

[WinScaleCoord\(\)](#)                      [WinScalePoint\(\)](#)

[WinScaleRectangle\(\)](#)                      [WinScreenGetAttribute\(\)](#)

[WinSetCoordinateSystem\(\)](#)   [WinUnscaleCoord\(\)](#)

[WinUnscalePoint\(\)](#)                      [WinUnscaleRectangle\(\)](#)

## 1.5x Display Feature Set

You can verify that this feature set is implemented by checking the version of the Window Manager. If the Window Manager version is 5 or greater, the 1.5x Display feature set is supported. To check the version of the Window Manager, use this call:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumWinVersion, &version);
```

---

Upon return, if version has a value of 5 or greater, the 1.5x Display feature set is present. Note that just because the 1.5x Display feature set is present, it isn't necessarily being used. You may want to check the density of the screen, as follows:

---

```
WinScreenGetAttribute(winScreenDensity, &attr);  
if (attr == kDensityOneAndAHalf) {  
    //the screen is one-and-a-half density  
}
```

---

## New Data Types

This feature set adds the following new data types.

### Window Constants

This feature set adds a new set of [Scaling Mode Values](#).

## Functions

This feature set adds the following functions.

### Window Functions

[WinGetScalingMode\(\)](#)

[WinSetScalingMode\(\)](#)

## Sound Stream Feature Set

The Sound Stream feature set adds a number of “stream” functions and constants to the Sound Manager. You can verify that this feature set is supported by checking for the Sound Manager’s version number. If the Sound Manager’s version feature is defined, the Sound Stream feature set is supported.

The following code shows how to check for the presence and proper version of the Sound Manager. Note that `expectedSndMgrVersionNum` should be replaced by the actual version number you expect (typically, `sndMgrVersionNum`).

---

```
UInt32 version;
Err err;

err = FtrGet(sysFileCSoundMgr, sndFtrIDVersion, &version);
if(err){
    // Sound Stream Feature Set not present
} else {
    // The Sound Stream Feature Set is present.
    // Check version number of Sound Manager,
    // if necessary
    if(version == expectedSndMgrVersionNum)
        // everything is OK
}
```

---

## Sound Stream Data Structures and Types

This feature set adds the following data structures:

[SndPtr](#)

[SndStreamRef](#)

[SndSampleType](#)

[SndStreamWidth](#)

[SndStreamMode](#)

## Sound Stream Enums and Constants

This feature set adds the following enums and constants:

### Sound Stream Enums and Constants

[SndSampleTag](#)

[Stereo Pan Constants](#)

[SndStreamModeTag](#)

[Volume Constants](#)

[SndStreamWidthTag](#)

[Sound Resource Playback Flags](#)

## Sound Stream Functions

This feature set adds the following functions.

### Sound Stream Functions

[SndPlayResource\(\)](#)

[SndStreamPause\(\)](#)

[SndStreamCreate\(\)](#)

[SndStreamSetPan\(\)](#)

[SndStreamCreateExtended\(\)](#) [SndStreamSetVolume\(\)](#)

[SndStreamDelete\(\)](#)

[SndStreamStart\(\)](#)

[SndStreamGetPan\(\)](#)

[SndStreamStop\(\)](#)

[SndStreamGetVolume\(\)](#)

In addition, the Sound Stream Feature Set defines the following callback functions:

[SndStreamBufferCallback\(\)](#)

[SndStreamVariableBufferCallback\(\)](#)

## 5.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 5.0 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to 0x05003000, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(5,0,0,sysROMStageRelease,0)
```

---

This feature set corresponds to version 5.0 of Palm OS 5.

The Palm OS Application Compatibility Environment (PACE) has its own version associated with it. You can obtain this version number with:

---

```
err = FtrGet('pace', 0, &paceVersion);
```

---

## Notifications

This feature set adds the following database-related notifications:

[sysNotifyDBCreatedEvent](#)   [sysNotifyDBDirtyEvent](#)  
[sysNotifyDBChangedEvent](#)

It also broadcasts the following notifications:

[sysNotifyAppLaunchingEvent](#)  
[sysNotifyAppQuittingEvent](#)  
[sysNotifyEventDequeuedEvent](#)  
[sysNotifyIdleTimeEvent](#)  
[sysNotifyInsPtEnableEvent](#)  
[sysNotifyKeyboardDialogEvent](#)  
[sysNotifyProcessPenStrokeEvent](#)  
[sysNotifyVirtualCharHandlingEvent](#)

## Functions

This feature set adds the following functions.

### ARM-Native Functions

[PceNativeCall\(\)](#)

## Functions and Traps not Supported by PACE

For various reasons a number of functions and traps are not supported by PACE. The following sections list those functions, grouped according to the reason that they are not implemented.

### Unimplemented “System Use Only” Functions

The following functions, which are documented as “System Use Only,” are not supported by the Palm OS Application Compatibility Environment (PACE).

|                                 |                          |
|---------------------------------|--------------------------|
| AlmAlarmCallback                | MemPtrResetLock          |
| AlmCancelAll                    | MemStoreSetInfo          |
| AlmDisplayAlarm                 | PenClose                 |
| AlmInit                         | PenGetRawPen             |
| AlmTimeChange                   | PenOpen                  |
| DmInit                          | ScrCompressScanLine      |
| EvtDequeueKeyEvent              | ScrCopyRectangle         |
| EvtGetSysEvent <sup>1</sup>     | ScrDeCompressScanLine    |
| EvtInitialize                   | ScrDrawChars             |
| EvtSetKeyQueuePtr               | ScrDrawNotify            |
| EvtSetPenQueuePtr               | ScrLineRoutine           |
| EvtSysInit                      | ScrRectangleRoutine      |
| ExgInit                         | ScrScreenInfo            |
| FrmAddSpaceForObject            | ScrSendUpdateArea        |
| FtrInit                         | SlkProcessRPC            |
| GrfFree                         | SlkSysPktDefaultResponse |
| GrfInit                         | SndInit                  |
| InsPtCheckBlink                 | SysBatteryDialog         |
| InsPtInitialize                 | SysColdBoot              |
| IntlInit                        | SysDoze                  |
| MemCardFormat                   | SysInit                  |
| MemHandleFlags                  | SysNewOwnerID            |
| MemHandleOwner                  | SysSemaphoreSet          |
| MemHandleResetLock <sup>1</sup> | SysUILaunch              |
| MemHeapFreeByOwnerID            | SysWantEvent             |
| MemHeapInit                     | TimInit                  |
| MemInit                         | UIInitialize             |
| MemInitHeapTable                | UIReset                  |
| MemKernelInit                   | WinAddWindow             |
| MemPtrFlags                     | WinRemoveWindow          |
| MemPtrOwner                     |                          |

1. Implemented on release ROMs but flagged as illegal on debug ROMs.

As a rule, functions and traps that are not documented should be treated as if they are unimplemented and should not be used by applications.

#### Implemented “System Use Only” Functions and Traps

Although marked “System Use Only,” a number of functions and traps are required by applications in the ROM, by Palm Debugger, by test applications, by scripting, or by some popular applications. Because of this, the following System Use Only functions and traps are supported by PACE. Because they are intended only for system use, however, applications should do what they can to avoid using them.

|                                            |                      |
|--------------------------------------------|----------------------|
| AlmEnableNotification                      | HwrDockStatus        |
| AttnAllowClose                             | HwrLEDAttributes     |
| AttnEnableNotification                     | HwrMemReadable       |
| AttnIndicatorAllow                         | HwrMemWritable       |
| AttnIndicatorAllowed                       | HwrVibrateAttributes |
| AttnIndicatorGetBlinkPattern               | MemChunkNew          |
| AttnIndicatorSetBlinkPattern               | MemHeapPtr           |
| AttnReopen                                 | PenRawToScreen       |
| DmResetRecordStates                        | PenScreenToRaw       |
| EvtEnqueuePenPoint                         | SysGetAppInfo        |
| <a href="#">EvtGetSilkscreenAreaList()</a> | SysLaunchConsole     |
| FileReadLow                                | SndSetDefaultVolume  |
| Find                                       | SysLCDContrast       |
| FrmActiveState                             | SysSetA5             |
| <a href="#">FrmHandleEvent()</a>           | SysSetPerformance    |
| HwrDelay                                   | SysSleep             |
|                                            | SysUIBusy            |
|                                            | WinDrawWindowFrame   |

#### Obsolete Functions and Traps

The following functions are not supported by PACE because they are obsolete.

|                                                |                                               |
|------------------------------------------------|-----------------------------------------------|
| <a href="#">FplAdd()</a> <sup>1</sup>          | <a href="#">FplFToA()</a> <sup>1</sup>        |
| <a href="#">FplAToF()</a> <sup>1</sup>         | <a href="#">FplLongToFloat()</a> <sup>1</sup> |
| <a href="#">FplBase10Info()</a> <sup>1</sup>   | <a href="#">FplMul()</a> <sup>1</sup>         |
| <a href="#">FplDiv()</a> <sup>1</sup>          | <a href="#">FplSub()</a> <sup>1</sup>         |
| <a href="#">FplFloatToLong()</a> <sup>1</sup>  | WiCmdV32                                      |
| <a href="#">FplFloatToULong()</a> <sup>1</sup> |                                               |

1. Implemented on release ROMs but flagged as illegal on debug ROMs.

### **‘NOP’ Functions and Traps**

These functions and traps should not be called by applications (many are documented as “System Use Only”). Because some third-party applications do call them, for backward compatibility they act as NOPs.

|                           |                     |
|---------------------------|---------------------|
| <a href="#">FplFree()</a> | SerReceiveISP       |
| <a href="#">FplInit()</a> | SrmSleep            |
| HwrEnableDataWrites       | SrmWake             |

### **Unimplemented Rare Functions and Traps**

These functions and traps are only used internally by Palm OS, by serial drivers, by OEM extensions, and the like. They are not implemented by PACE.

|                                      |                                         |
|--------------------------------------|-----------------------------------------|
| ConGetS                              | FlashErase                              |
| ConPutS                              | FlashProgram                            |
| <a href="#">DayDrawDays()</a>        | <a href="#">IntlSetRoutineAddress()</a> |
| <a href="#">DayDrawDaySelector()</a> | MemGetRomNVParams                       |
| DbgCommSettings                      | MemNVParams                             |
| DbgGetMessage                        | OEMDispatch <sup>1</sup>                |
| DlkDispatchRequest                   | <a href="#">ResLoadForm()</a>           |
| DlkStartServer                       | <a href="#">SlkSetSocketListener()</a>  |
| DmMoveOpenDBContext                  | SysNotifyDatabaseAdded                  |
| DmOpenDBWithLocale                   | SysNotifyDatabaseRemoved                |
| FlashCompress                        | <a href="#">SysSetTrapAddress()</a>     |

1. Supported if the OEM supports the trap.

## 5.1 New Feature Set

You can check that this feature set is implemented by checking that the system version is 5.1 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

The `romVersion` parameter should be greater than or equal to `0x05103000`, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(5,1,0,sysROMStageRelease,0)
```

---

This feature set corresponds to version 5.1 of Palm OS 5.

### Net Library Interface Settings

This feature set adds the following Net Library Interface Settings:

|                              |                                     |
|------------------------------|-------------------------------------|
| <code>DriverVersion</code>   | <code>80211AccessPointBSSID</code>  |
| <code>FirmwareVersion</code> | <code>80211AssociationStatus</code> |
| <code>FirmwareDate</code>    | <code>80211MKKCallSign</code>       |
| <code>80211Device</code>     | <code>80211CountryTest</code>       |
| <code>80211ESSID</code>      |                                     |

See [NetLibIFSettingGet\(\)](#) for a description of each of the above settings.

### CPM Library

This feature set includes the Cryptographic Provider Manager (CPM) shared library. The CPM library isn't automatically loaded upon system boot: before making use of the CPM library you must first load it, using `SysLibFind` and `SysLibLoad`.

The CPM library defines a number of constants:

- [AP Capability Constants](#)
- [Block Encryption Mode Constants](#)
- [Cipher Algorithm Constants](#)
- [Export Encoding Constants](#)

- [Hashing Algorithm Constants](#)
- [Key Class Constants](#)
- [Key Usage Constants](#)
- [Plaintext Padding Constants](#)

The following structures are defined as part of the CPM library:

|                                         |                                      |
|-----------------------------------------|--------------------------------------|
| <a href="#">APCipherInfoStruct</a>      | <a href="#">APProviderInfoStruct</a> |
| <a href="#">APHashInfoStruct</a>        | <a href="#">APVerifyInfoStruct</a>   |
| <a href="#">APKeyInfoStruct</a>         | <a href="#">CPMInfoStruct</a>        |
| <a href="#">APProviderContextStruct</a> |                                      |

Finally, the CPM library contains the following functions:

|                                          |                                           |
|------------------------------------------|-------------------------------------------|
| <a href="#">CPMLibDecrypt()</a>          | <a href="#">CPMLibHash()</a>              |
| <a href="#">CPMLibDecryptFinal()</a>     | <a href="#">CPMLibHashFinal()</a>         |
| <a href="#">CPMLibDecryptInit()</a>      | <a href="#">CPMLibHashInit()</a>          |
| <a href="#">CPMLibDecryptUpdate()</a>    | <a href="#">CPMLibImportCipherInfo()</a>  |
| <a href="#">CPMLibEncrypt()</a>          | <a href="#">CPMLibImportHashInfo()</a>    |
| <a href="#">CPMLibEncryptFinal()</a>     | <a href="#">CPMLibImportKeyInfo()</a>     |
| <a href="#">CPMLibEncryptInit()</a>      | <a href="#">CPMLibImportVerifyInfo()</a>  |
| <a href="#">CPMLibEncryptUpdate()</a>    | <a href="#">CPMLibReleaseCipherInfo()</a> |
| <a href="#">CPMLibExportCipherInfo()</a> | <a href="#">CPMLibReleaseHashInfo()</a>   |
| <a href="#">CPMLibExportHashInfo()</a>   | <a href="#">CPMLibReleaseKeyInfo()</a>    |
| <a href="#">CPMLibExportKeyInfo()</a>    | <a href="#">CPMLibReleaseVerifyInfo()</a> |
| <a href="#">CPMLibExportVerifyInfo()</a> | <a href="#">CPMLibVerify()</a>            |
| <a href="#">CPMLibGenerateKey()</a>      | <a href="#">CPMLibVerifyFinal()</a>       |
| <a href="#">CPMLibGetInfo()</a>          | <a href="#">CPMLibVerifyInit()</a>        |
| <a href="#">CPMLibGetProviderInfo()</a>  | <a href="#">CPMLibVerifyUpdate()</a>      |

## SSL Library

The 5.1 New Feature Set includes the Secure Sockets Layer (SSL) shared library. The SSL library isn't automatically loaded upon system boot: before making use of the SSL library you must first load it and open it, using code similar to the following:

---

```
Err error;
UInt16 libRef;

if ( SysLibFind( kSslDBName, &libRef ) != 0 )
{
    error = SysLibLoad(kSslLibType, kSslLibCreator, &libRef);
}
/* error checking goes here. */

error = SslLibOpen( libRef );
...
```

---

## SSL Library Structures and Data Types

The SSL library defines a number of structures and data types:

|                                           |                                         |
|-------------------------------------------|-----------------------------------------|
| <a href="#"><u>SslAttribute</u></a>       | <a href="#"><u>SslExtendedItems</u></a> |
| <a href="#"><u>SslContext</u></a>         | <a href="#"><u>SslIoBuf</u></a>         |
| <a href="#"><u>SslLib</u></a>             | <a href="#"><u>SslLibCallback</u></a>   |
| <a href="#"><u>SslCallback</u></a>        | <a href="#"><u>SslSession</u></a>       |
| <a href="#"><u>SslCipherSuiteInfo</u></a> | <a href="#"><u>SslSocket</u></a>        |
| <a href="#"><u>SslExtendedItem</u></a>    | <a href="#"><u>SslVerify</u></a>        |

## SSL Library Functions

|                                            |                                        |
|--------------------------------------------|----------------------------------------|
| <a href="#"><u>SslClose()</u></a>          | <a href="#"><u>SslLibOpen()</u></a>    |
| <a href="#"><u>SslConsume()</u></a>        | <a href="#"><u>SslLibGetLong()</u></a> |
| <a href="#"><u>SslContextCreate()</u></a>  | <a href="#"><u>SslLibGetPtr()</u></a>  |
| <a href="#"><u>SslContextDestroy()</u></a> | <a href="#"><u>SslLibSetLong()</u></a> |
| <a href="#"><u>SslContextGetLong()</u></a> | <a href="#"><u>SslLibSetPtr()</u></a>  |
| <a href="#"><u>SslContextGetPtr()</u></a>  | <a href="#"><u>SslOpen()</u></a>       |
| <a href="#"><u>SslContextSetLong()</u></a> | <a href="#"><u>SslPeek()</u></a>       |
| <a href="#"><u>SslContextSetPtr()</u></a>  | <a href="#"><u>SslRead()</u></a>       |
| <a href="#"><u>SslFlush()</u></a>          | <a href="#"><u>SslReceive()</u></a>    |
| <a href="#"><u>SslLibClose()</u></a>       | <a href="#"><u>SslSend()</u></a>       |
| <a href="#"><u>SslLibCreate()</u></a>      | <a href="#"><u>SslWrite()</u></a>      |
| <a href="#"><u>SslLibDestroy()</u></a>     |                                        |

In addition, the SSL library defines one callback function:

- [SslCallbackFunc\(\)](#)

## SSL Library Attributes and Macros

You interact with SSL attributes using the following macros:

- [SslContextGet\\_Attribute \(integer version\)\(\)](#)
- [SslContextGet\\_Attribute \(pointer version\)\(\)](#)
- [SslLibSet\\_Attribute \(integer version\)\(\)](#)
- [SslContextSet\\_Attribute \(pointer version\)\(\)](#)
- [SslLibGet\\_Attribute \(integer version\)\(\)](#)
- [SslLibGet\\_Attribute \(pointer version\)\(\)](#)
- [SslLibSet\\_Attribute \(integer version\)\(\)](#)
- [SslLibSet\\_Attribute \(pointer version\)\(\)](#)

The attributes that you can manipulate with the above macros are:

| <a href="#"><u>LastAlert</u></a>           | <a href="#"><u>WriteBufPending</u></a> |
| <a href="#"><u>LastApi</u></a>             |                                        |

## Graffiti 2 Feature Set

Version 4.1.2 of Palm OS and version 5.2 of Palm OS 5 use the Graffiti® 2 handwriting recognition engine, which is based on Jot® technology. The Graffiti Manager still provides the interface to the new engine; however, some functions have been deprecated.

You can check that this feature set is implemented by checking for the existence of the Graffiti 2 dynamic ID, which is set by the Graffiti 2 library. Use code similar to the following:

---

```
if (!FtrGet('grft', 1110, &g2DynamicID) ||
```

```
!FtrGet('grf2', 1110, &g2DynamicID)) {  
    // Graffiti 2 feature set is present.  
}
```

---

Note that the Graffiti 2 creator code changed between version 4.1.2 and version 5.2, so both [FtrGet\(\)](#) calls are necessary.

### Deprecated Functions

The following functions are deprecated if this feature set is present:

[GrfAddPoint\(\)](#)

[GrfFlushPoints\(\)](#)

[GrfInitState\(\)](#) (this was reinstated in later versions)

[GrfCleanState\(\)](#)

[GrfMatch\(\)](#)

[GrfFilterPoints\(\)](#)

[GrfGetNumPoints\(\)](#)

[GrfGetPoint\(\)](#)

[GrfFindBranch\(\)](#)

[GrfMatchGlyph\(\)](#)

[GrfGetGlyphMapping\(\)](#)

In addition, the capsLock and numLock parameters to [GrfSetState\(\)](#) and [GrfGetState\(\)](#) do not apply for the Graffiti 2 recognizer.

Note that the Graffiti Shift Indicator APIs work as normal.

## 5.3SC New Feature Set

You can check that this feature set is implemented by checking that the system version is 5.3 or higher. Use this [FtrGet\(\)](#) call:

---

```
err = FtrGet(sysFtrCreator,  
sysFtrNumROMVersion, &romVersion);
```

---

## Compatibility Guide

### 5.3SC New Feature Set

---

The `romVersion` parameter should be greater than or equal to `0x05303000`, which can be constructed using the `sysMakeROMVersion` macro:

---

```
sysMakeROMVersion(5,3,0,sysROMStageRelease,0)
```

---

This feature set corresponds to version 5.3SC of Palm OS 5.

## Functions

This feature set adds the following functions.

### Form Manager Functions

`FrmGetDIAPolicyAttr()`

`FrmSetDIAPolicyAttr()`

These functions are documented in the book *Applications and Dynamic Input Areas*.

### Glue Functions

[`LmGlueGetSystemLocale\(\)`](#)

### Pen Input Manager Functions

`PINGetInputAreaState()`

`PINGetInputTriggerState()`

`PINSetInputAreaState()`

`PINSetInputTriggerState()`

`StatGetAttribute()`

`StatHide()`

`StatShow()`

`SysGetOrientation()`

`SysSetOrientation()`

`SysGetOrientationTriggerState()`

`SysSetOrientationTriggerState()`

These functions are documented in the book *Applications and Dynamic Input Areas*.

### Window Manager Functions

`WinSetConstraintsSize()`

This function is documented in the book *Applications and Dynamic Input Areas*.

### Events

This feature set adds the following event.

`winDisplayChangedEvent`

This event is documented in the book *Applications and Dynamic Input Areas*.

### Notifications

This feature set adds the following notifications.

[`sysNotifyGsiDrawIndicator`](#)

[`sysNotifyInputAreaDrawingEvent`](#)

[`sysNotifyInputAreaPendownEvent`](#)

[`sysNotifySelectDay`](#)

Additionally, the following notification is documented in the book *Applications and Dynamic Input Areas*.

`sysNotifyDisplayResizedEvent`

### Existing Functions that Changed

The following functions that existed prior to 5.3SC have changed in release 5.3SC:

The `capsLock` and `numLock` parameters to [`GrfSetState\(\)`](#) and [`GrfGetState\(\)`](#) now apply to the Graffiti 2 recognizer. In the Palm OS 5 operating system, Graffiti 2 was introduced in Palm OS 5.2. In that initial implementation, these two parameters did not apply.

In Palm OS 5.2, [`GrfInitState\(\)`](#) was deprecated and nonfunctional. This function is now supported again in Palm OS

## Compatibility Guide

### 5.3SC New Feature Set

---

5.3SC. (Actually, it was reinstated in Palm OS version 5.2.1 and later.)

In the following functions, the `numOfElements` parameter was changed to a `UInt16` type: [SysBinarySearch](#), [SysInsertionSort](#), and [SysQSort](#).

# 1.0 Float Manager

---

This section provides reference material for the Palm OS 1.0 float manager. In Palm OS 1.0, the float manager API is declared in the header file `FloatMgr.h`. In Palm OS 2.0, this file was renamed to `FloatMgrOld.h`. In Palm OS 3.5, this file was made private.

---

**NOTE:** New applications should no longer use the 1.0 Float Manager. See [Chapter 32, “Float Manager,”](#) on page 667 for the functions now provided by the Float Manager.

---

## Float Manager Functions

### FplAdd Function

|                      |                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Add two floating-point numbers (returns $a + b$ ).                                                                                                                                                       |
| <b>Prototype</b>     | <code>FloatType FplAdd (FloatType a, FloatType b)</code>                                                                                                                                                 |
| <b>Parameters</b>    | <code>a</code> , <code>b</code><br>The floating-point numbers.                                                                                                                                           |
| <b>Returns</b>       | Returns the normalized floating-point result of the addition.                                                                                                                                            |
| <b>Comments</b>      | Under Palm OS® 2.0 and later, most applications will want to use the arithmetic symbols instead. See the <a href="#">“Floating-Point”</a> section in the <i>Palm OS Programmer’s Companion</i> , vol. I. |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ).                                                                                                                          |

## 1.0 Float Manager

*FplAToF*

---

### FplAToF Function

|                      |                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert a zero-terminated ASCII string to a floating-point number. The string must be in the format: [-]x[.]yyyyyyyy[e[-]zz] |
| <b>Prototype</b>     | FloatType FplAToF (char* s)                                                                                                  |
| <b>Parameters</b>    | s<br>Pointer to the ASCII string.                                                                                            |
| <b>Returns</b>       | Returns the floating-point number.                                                                                           |
| <b>Comments</b>      | The mantissa of the number is limited to 32 bits.                                                                            |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ).                                              |
| <b>See Also</b>      | <a href="#">FplFToA()</a> , <a href="#">FplFree()</a> , <a href="#">FplInit()</a>                                            |

### FplBase10Info Function

|                   |                                                                                                                                                                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Extract detailed information on the base 10 form of a floating-point number: the base 10 mantissa, exponent, and sign.                                                                                                                                                 |
| <b>Prototype</b>  | Err FplBase10Info (FloatType a, ULong* mantissaP,<br>Int* exponentP, Int* signP)                                                                                                                                                                                       |
| <b>Parameters</b> | a<br>The floating-point number.<br>mantissaP<br>The base 10 mantissa (return value).<br>exponentP<br>The base 10 exponent (return value).<br>signP<br>The sign, 1 or -1 (return value).                                                                                |
| <b>Returns</b>    | Returns an error code, or 0 if no error.                                                                                                                                                                                                                               |
| <b>Comments</b>   | The mantissa is normalized so it contains at least kMaxSignificantDigits significant digits when printed as an integer value.<br><br>FplBase10Info reports that zero is "negative"; that is, it returns a one for xSign. If this is a problem, a simple workaround is: |

---

```
if (xMantissa == 0) {  
    xSign = 0;  
}
```

---

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

## FplDiv Function

**Purpose** Divide two floating-point numbers (result = dividend/divisor).

**Prototype** FloatType FplDiv (FloatType dividend,  
FloatType divisor)

**Parameters** dividend  
Floating-point dividend.  
divisor  
Floating-point divisor.

**Returns** Returns the normalized floating-point result of the division.  
Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the [“Floating-Point”](#) section in the *Palm OS Programmer’s Companion*, vol. I.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

## FplFloatToLong Function

**Purpose** Convert a floating-point number to a long integer.

**Prototype** Long FplFloatToLong (FloatType f)

**Parameters** f  
Floating-point number to be converted.

**Returns** Returns the long integer.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

**See Also** [FplLongToFloat\(\)](#), [FplFloatToULong\(\)](#)

## 1.0 Float Manager

### *FplFloatToULong*

---

#### **FplFloatToULong Function**

|                      |                                                                                 |
|----------------------|---------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert a floating-point number to an unsigned long integer.                    |
| <b>Prototype</b>     | <code>ULong FplFloatToULong (FloatType f)</code>                                |
| <b>Parameters</b>    | <div><code>f</code><br/>Floating-point number to be converted.</div>            |
| <b>Returns</b>       | Returns an unsigned long integer.                                               |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ). |
| <b>See Also</b>      | <a href="#">FplLongToFloat()</a> , <a href="#">FplFloatToLong()</a>             |

#### **FplFree Function**

|                      |                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Release all memory allocated by the floating-point initialization.                                           |
| <b>Prototype</b>     | <code>void FplFree()</code>                                                                                  |
| <b>Parameters</b>    | None.                                                                                                        |
| <b>Returns</b>       | Returns nothing.                                                                                             |
| <b>Comments</b>      | Applications must call this routine after they've called other functions that are part of the float manager. |
| <b>Compatibility</b> | If <a href="#">5.0 New Feature Set</a> is present, this function acts as a NOP.                              |
| <b>See Also</b>      | <a href="#">FplInit()</a>                                                                                    |

#### **FplFToA Function**

|                   |                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Convert a floating-point number to a zero-terminated ASCII string in exponential format: <code>[-]x.yyyyyyye[-]zz</code>          |
| <b>Prototype</b>  | <code>Err FplFToA (FloatType a, char* s)</code>                                                                                   |
| <b>Parameters</b> | <div><code>a</code><br/>Floating-point number.</div> <div><code>s</code><br/>Pointer to buffer to contain the ASCII string.</div> |
| <b>Returns</b>    | Returns an error code, or 0 if no error.                                                                                          |

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

**See Also** [FplAToF\(\)](#), [FplFree\(\)](#), [FplInit\(\)](#)

## **FplInit Function**

**Purpose** Initialize the floating-point conversion routines.

Allocate space in the system heap for floating-point globals.

Initialize the `tenPowers` array in the globals area to the powers of 10 from -99 to +99 in floating-point format.

**Prototype** `Err FplInit()`

**Parameters** None.

**Returns** Returns an error code, or 0 if no error.

**Comments** Applications must call this routine before calling any other Fpl function.

**Compatibility** If [5.0 New Feature Set](#) is present, this function acts as a NOP.

**See Also** [FplFree\(\)](#)

## **FplLongToFloat Function**

**Purpose** Convert a long integer to a floating-point number.

**Prototype** `FloatType FplLongToFloat (Long x)`

**Parameters** `x`  
A long integer.

**Returns** Returns the floating-point number.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

## 1.0 Float Manager

### *FplMul*

---

#### **FplMul Function**

|                      |                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Multiply two floating-point numbers.                                                                                                                                                                    |
| <b>Prototype</b>     | <code>FloatType FplMul (FloatType a, FloatType b)</code>                                                                                                                                                |
| <b>Parameters</b>    | <code>a, b</code><br>The floating-point numbers.                                                                                                                                                        |
| <b>Returns</b>       | Returns the normalized floating-point result of the multiplication.                                                                                                                                     |
| <b>Comments</b>      | Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the <a href="#">“Floating-Point”</a> section in the <i>Palm OS Programmer’s Companion</i> , vol. I. |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ).                                                                                                                         |

#### **FplSub Function**

|                      |                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Subtract two floating-point numbers (returns <code>a - b</code> ).                                                                                                                                      |
| <b>Prototype</b>     | <code>FloatType FplSub (FloatType a, FloatType b)</code>                                                                                                                                                |
| <b>Parameters</b>    | <code>a, b</code><br>The floating-point numbers.                                                                                                                                                        |
| <b>Returns</b>       | Returns the normalized floating-point result of the subtraction.                                                                                                                                        |
| <b>Comments</b>      | Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the <a href="#">“Floating-Point”</a> section in the <i>Palm OS Programmer’s Companion</i> , vol. I. |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ).                                                                                                                         |

# Palm OS Error Codes

---

This appendix lists most of the error codes used by the Palm OS, and is sorted by value to serve as an aid to debugging.

| Code   | Identifier               | Description                                                                   |
|--------|--------------------------|-------------------------------------------------------------------------------|
| 0x0000 | errNone                  | No error                                                                      |
| 0x0000 | hostErrBase              | No error                                                                      |
| 0x0000 | inetErrNone              | No error                                                                      |
| 0x0100 | memErrorClass            | Memory Manager errors                                                         |
| 0x0101 | memErrChunkLocked        | The associated memory chunk is locked.                                        |
| 0x0102 | memErrNotEnoughSpace     | A memory error occurred.                                                      |
| 0x0103 | memErrInvalidParam       | One of the function's parameters is invalid or the requested size is too big. |
| 0x0104 | memErrChunkNotLocked     |                                                                               |
| 0x0105 | memErrCardNotPresent     | The specified card can't be found.                                            |
| 0x0106 | memErrNoCardHeader       |                                                                               |
| 0x0107 | memErrInvalidStoreHeader | The specified card has no storage RAM.                                        |
| 0x0108 | memErrRAMOnlyCard        | The specified card has no storage RAM.                                        |
| 0x0109 | memErrWriteProtect       |                                                                               |
| 0x010a | memErrNoRAMOnCard        |                                                                               |
| 0x010b | memErrNoStore            |                                                                               |
| 0x010c | memErrROMOnlyCard        |                                                                               |
| 0x0200 | dmErrorClass             | Data Manager errors                                                           |

## Palm OS Error Codes

---

| Code   | Identifier             | Description                                                                                                      |
|--------|------------------------|------------------------------------------------------------------------------------------------------------------|
| 0x0201 | dmErrMemError          | A memory error occurred.                                                                                         |
| 0x0202 | dmErrIndexOutOfRange   | The specified index is out of range.                                                                             |
| 0x0203 | dmErrInvalidParam      | The function received an invalid parameter.                                                                      |
| 0x0204 | dmErrReadOnly          | You've attempted to write to or modify a database that is in read-only mode.                                     |
| 0x0205 | dmErrDatabaseOpen      | The function cannot be performed on an open database, and the database is open.                                  |
| 0x0206 | dmErrCantOpen          | The database cannot be opened.                                                                                   |
| 0x0207 | dmErrCantFind          | The specified resource can't be found.                                                                           |
| 0x0208 | dmErrRecordInWrongCard | You've attempted to attach a record to a database when the record and database reside on different memory cards. |
| 0x0209 | dmErrCorruptDatabase   | The database is corrupted.                                                                                       |
| 0x020a | dmErrRecordDeleted     | The record has been deleted.                                                                                     |
| 0x020b | dmErrRecordArchived    | The function requires that the record not be archived, but it is.                                                |
| 0x020c | dmErrNotRecordDB       | You've attempted to perform a record function on a resource database.                                            |
| 0x020d | dmErrNotResourceDB     | You've attempted to perform a resource manager function on a record database.                                    |
| 0x020e | dmErrROMBased          | You've attempted to delete or modify a ROM-based database.                                                       |
| 0x020f | dmErrRecordBusy        | The function requires that the record not be busy, but it is.                                                    |
| 0x0210 | dmErrResourceNotFound  | The resource can't be found.                                                                                     |
| 0x0211 | dmErrNoOpenDatabase    | The function is to search all open databases, but there are none.                                                |

| Code   | Identifier                | Description                                                                                                       |
|--------|---------------------------|-------------------------------------------------------------------------------------------------------------------|
| 0x0212 | dmErrInvalidCategory      |                                                                                                                   |
| 0x0213 | dmErrNotValidRecord       | The record handle is invalid.                                                                                     |
| 0x0214 | dmErrWriteOutOfBounds     | A write operation exceeded the bounds of the record.                                                              |
| 0x0215 | dmErrSeekFailed           | The operation of seeking the next record in the category failed.                                                  |
| 0x0216 | dmErrAlreadyOpenForWrites | The database is already open with write access.                                                                   |
| 0x0217 | dmErrOpenedByAnotherTask  | You've attempted to open a database that another task already has open.                                           |
| 0x0218 | dmErrUniqueIDNotFound     | A record with the specified unique ID can't be found.                                                             |
| 0x0219 | dmErrAlreadyExists        | Another database with the same name already exists in RAM store.                                                  |
| 0x021a | dmErrInvalidDatabaseName  | The name you've specified for the database is invalid.                                                            |
| 0x021b | dmErrDatabaseProtected    | The database is marked as protected.                                                                              |
| 0x021c | dmErrDatabaseNotProtected | <a href="#">DmDatabaseProtect()</a> failed to protect the specified database.                                     |
| 0x0300 | serErrorClass             | Serial Manager errors                                                                                             |
| 0x0301 | serErrBadParam            | One of the function's parameters is invalid. See the Serial Manager function's description for additional detail. |
| 0x0302 | serErrBadPort             | The specified port doesn't exist.                                                                                 |
| 0x0303 | serErrNoMem               |                                                                                                                   |
| 0x0304 | serErrBadConnID           |                                                                                                                   |
| 0x0305 | serErrTimeOut             | Unable to receive data within the specified timeout period.                                                       |

## Palm OS Error Codes

---

| Code   | Identifier                | Description                                                                                                                                                                                     |
|--------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0306 | serErrLineErr             | A line error occurred during the receipt of data. Use <a href="#">SrmGetStatus()</a> to obtain the exact line error.                                                                            |
| 0x0307 | serErrAlreadyOpen         | The Serial Manager already has a port open, or the specified port already has an installed foreground or background owner.                                                                      |
| 0x0308 | serErrStillOpen           |                                                                                                                                                                                                 |
| 0x0309 | serErrNotOpen             | The serial port is not open.                                                                                                                                                                    |
| 0x030a | serErrNotSupported        | The specified port is not the foreground port, the specified op code is not supported in the current configuration, the port is a yielded port, or the feature isn't supported by the hardware. |
| 0x030b | serErrNoDevicesAvail      | No serial devices could be found.                                                                                                                                                               |
| 0x030c | serErrConfigurationFailed | The port needs time to configure, and the configuration has failed.                                                                                                                             |
| 0x0400 | slkErrorClass             | Serial Link Manager errors                                                                                                                                                                      |
| 0x0401 | slkErrChecksum            |                                                                                                                                                                                                 |
| 0x0402 | slkErrFormat              |                                                                                                                                                                                                 |
| 0x0403 | slkErrBuffer              |                                                                                                                                                                                                 |
| 0x0404 | slkErrTimeOut             |                                                                                                                                                                                                 |
| 0x0405 | slkErrHandle              |                                                                                                                                                                                                 |

| 0x2900 | expErrorClass                            | Expansion Manager and Slot Driver<br>Library errors |

| Code   | Identifier                  | Description                                                                                          |
|--------|-----------------------------|------------------------------------------------------------------------------------------------------|
| 0x2901 | expErrUnsupportedOperation  | The operation is unsupported or undefined.                                                           |
| 0x2902 | expErrNotEnoughPower        | The required power is not available.                                                                 |
| 0x2903 | expErrCardNotPresent        | There is no card present in the given slot.                                                          |
| 0x2904 | expErrInvalidSlotRefNum     | The slot reference number is not valid.                                                              |
| 0x2905 | expErrSlotDeallocated       | The slot reference number is within the valid range, but the slot has been deallocated.              |
| 0x2906 | expErrCardNoSectorReadWrite | The card does not support the slot driver block read/write API.                                      |
| 0x2907 | expErrCardReadOnly          | The card supports the slot driver block read/write API but the card is read only.                    |
| 0x2908 | expErrCardBadSector         | The card supports the slot driver block read/write API but the sector is bad.                        |
| 0x2909 | expErrCardProtectedSector   | The card supports the slot driver block read/write API but the sector is protected.                  |
| 0x290a | expErrNotOpen               | The slot driver library has not been opened.                                                         |
| 0x290b | expErrStillOpen             | The slot driver library is still open; it may have been opened more than once.                       |
| 0x290c | expErrUnimplemented         | The call is unimplemented.                                                                           |
| 0x290d | expErrEnumerationEmpty      | There are no values remaining to enumerate.                                                          |
| 0x290e | expErrIncompatibleAPIVer    | The API version of the underlying slot driver is not supported by this version of Expansion Manager. |
| 0x2a00 | vfsErrorClass               | Virtual Filesystem Manager and Filesystem Library errors                                             |
| 0x2a01 | vfsErrBufferOverflow        | The supplied buffer is too small.                                                                    |
| 0x2a02 | vfsErrFileGeneric           | Generic file error.                                                                                  |

## Palm OS Error Codes

---

| Code   | Identifier                 | Description                                                                                                |
|--------|----------------------------|------------------------------------------------------------------------------------------------------------|
| 0x2a03 | vfsErrFileBadRef           | The file reference is invalid: it has been closed or was not obtained from <a href="#">VFSFileOpen()</a> . |
| 0x2a04 | vfsErrFileStillOpen        | Returned from the underlying file system's delete function if the file is still open.                      |
| 0x2a05 | vfsErrFilePermissionDenied | The requested permissions could not be granted.                                                            |
| 0x2a06 | vfsErrFileAlreadyExists    | A file with this name exists already in this location.                                                     |
| 0x2a07 | vfsErrFileEOF              | The file pointer is at the end of the file.                                                                |
| 0x2a08 | vfsErrFileNotFound         | The file was not found at the specified location.                                                          |
| 0x2a09 | vfsErrVolumeBadRef         | The volume reference number is invalid.                                                                    |
| 0x2a0a | vfsErrVolumeStillMounted   | Returned from the underlying file system's format function if the volume is still mounted.                 |
| 0x2a0b | vfsErrNoFileSystem         | None of the installed file systems support this operation.                                                 |
| 0x2a0c | vfsErrBadData              | The operation could not be completed because of invalid data.                                              |
| 0x2a0d | vfsErrDirNotEmpty          | The directory is not empty and therefore cannot be deleted.                                                |
| 0x2a0e | vfsErrBadName              | Invalid filename, path, or volume label.                                                                   |
| 0x2a0f | vfsErrVolumeFull           | There is insufficient space left on the volume.                                                            |
| 0x2a10 | vfsErrUnimplemented        |                                                                                                            |
| 0x2a11 | vfsErrNotADirectory        | This operation can only performed on a directory.                                                          |

| Code   | Identifier                  | Description                                                                                        |
|--------|-----------------------------|----------------------------------------------------------------------------------------------------|
| 0x2a12 | vfsErrIsADirectory          | This operation can only be performed on a regular file, not a directory.                           |
| 0x2a13 | vfsErrDirectoryNotFound     | Returned when the path leading up to the file does not exist.                                      |
| 0x2a14 | vfsErrNameShortened         | A volume name or filename was automatically shortened to conform to the file system specification. |
| 0x2b00 | lmErrorClass                | Locale Manager errors                                                                              |
| 0x2b01 | lmErrUnknownLocale          | The locale could not be found.                                                                     |
| 0x2b02 | lmErrBadLocaleIndex         | The locale index is out of range.                                                                  |
| 0x2b03 | lmErrBadLocaleSettingChoice | The locale setting choice parameter contains an unknown or unsupported value.                      |
| 0x2b04 | lmErrSettingDataOverflow    | The output buffer is too small to hold the setting's value.                                        |
