**Purpose** This enumeration defines a set of commands that tell [SndPlaySmf\(\)](#) whether it should play the file or simply return the duration of the file in milliseconds.

**Prototype**

```
enum SndSmfCmdEnumTag {  
    sndSmfCmdPlay = 1,  
    sndSmfCmdDuration,  
}
```

### **Value Descriptions**

|                   |                                                                            |
|-------------------|----------------------------------------------------------------------------|
| sndSmfCmdPlay     | Play the specified Standard MIDI File.                                     |
| sndSmfCmdDuration | Return the duration, in milliseconds, of the specified Standard MIDI File. |

## **sndSmfPlayAllMilliSec**

Represents the (temporal) far end of a MIDI file. You can use this constant as the value of the dwEndMilliSec field of the [SndSmfOptionsType](#) structure before passing the structure to [SndPlaySmf\(\)](#). This setting tells the function to play the entire file.

```
#define sndSmfPlayAllMilliSec 0xFFFFFFFFFUL
```

## **System Beeps Enum**

**Purpose** This enumeration declares a set of constants that represent pre-defined system beeps. In order to play one of these sounds, pass the corresponding value to [SndPlaySystemSound\(\)](#).

**Prototype**

```
typedef enum SndSysBeepTag {  
    sndInfo = 1,  
    sndWarning,  
    sndError,  
    sndStartUp,  
    sndAlarm,  
}
```

```
    sndConfirmation,  
    sndClick  
}
```

### Value Descriptions

|                              |                                                                               |
|------------------------------|-------------------------------------------------------------------------------|
| <code>sndInfo</code>         | Heralds non-crucial information.                                              |
| <code>sndWarning</code>      | Grabs the user's attention                                                    |
| <code>sndError</code>        | Indicates an illegal operation.                                               |
| <code>sndStartUp</code>      | Played at device start up time.                                               |
| <code>sndAlarm</code>        | Generic alarm sound; note that this is <i>not</i> the Datebook's alarm sound. |
| <code>sndConfirmation</code> | Indicates approval or acceptance.                                             |
| <code>sndClick</code>        | The button click sound.                                                       |

## Simple Sound Functions

### SndCreateMidiList Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Generate a list of MIDI records.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Boolean SndCreateMidiList (UInt32 creator,<br/>    Boolean multipleDBs, UInt16 *recordCount,<br/>    MemHandle *recordList)</pre>                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>creator</i><br/>Creator ID of the database in which the function looks for MIDI records. Pass 0 to search all databases.</p> <p>→ <i>multipleDBs</i><br/>Pass true to search multiple databases for MIDI records.<br/>Pass false to search only in the first database that meets the search criteria.</p> <p>← <i>recordCount</i><br/>Returns the number of MIDI records that were found.</p> |

|                      |                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <i>← recordList</i><br>Returns a pointer to an array of <a href="#">SndMidiListItemType</a> structures, one structure for each record that was found. |
| <b>Returns</b>       | Returns <code>true</code> if records were found, <code>false</code> otherwise.                                                                        |
| <b>Compatibility</b> | Implemented in Palm OS 3.0 and later.                                                                                                                 |

## SndDoCmd Function

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Ask the Sound Manager to perform a simple sound synthesis operation.                                                                                 |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                              |
| <b>Prototype</b>   | <code>Err SndDoCmd (void* channelP,<br/>SndCommandPtr commandP, Boolean noWait)</code>                                                               |
| <b>Parameters</b>  | <i>→ channelP</i><br>Pointer to the sound channel on which you want to perform the operation. Pass <code>NULL</code> for the “shared” sound channel. |

---

**IMPORTANT:** The Sound Manager only supports one channel of sound synthesis: You must pass `NULL` as the value of `channelP`.

---

|                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>→ commandP</i><br>Pointer to a <a href="#">SndCommandType</a> structure that describes the operation and contains any associated parameters. See the Comments section, below, for the set of sound commands and their associated parameters. |
| <i>→ noWait</i><br>Sets the function to be asynchronous ( <code>true</code> ) or synchronous ( <code>false</code> ) with respect to the caller.                                                                                                 |

---

**IMPORTANT:** `SndDoCmd` is always synchronous: The `noWait` value is currently ignored.

---

|                |                                                                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b> | Returns <code>errNone</code> if the operation completed successfully, or one of the following if an error occurred:<br><br><code>sndErrBadParam</code><br>Invalid parameter. |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# Sound Manager

## SndDoCmd

sndErrBadChannel  
Invalid channel pointer.

sndErrQFull  
The sound queue is full.

**Comments** The sound operations that are performed by SndDoCmd are encapsulated in the [SndCommandType](#) structure. The cmd field represents the operation, while the param fields are data that's passed to the operation. The operations and data that SndDoCmd supports are described in the following table.

**Table 45.1 SndDoCmd commands and parameters**

| Command               | Function                                                                                                                                      | Parameters                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sndCmdFreqDurationAmp | Plays a tone. SndDoCmd blocks until the tone has finished.                                                                                    | param1 is the tone's frequency in Hertz.<br><br>param2 is its duration in milliseconds<br><br>param3 is its amplitude in the range [0, sndMaxAmp]. If the amplitude is 0, the sound isn't played and the function returns immediately. |
| sndCmdFrqOn           | Initiates a tone. SndDoCmd returns immediately while the tone plays in the background. Subsequent sound playback requests interrupt the tone. | param1 is the tone's frequency in Hertz.<br><br>param2 is its duration in milliseconds<br><br>param3 is its amplitude in the range [0, sndMaxAmp]. If the amplitude is 0, the sound isn't played and the function returns immediately. |

**Table 45.1 SndDoCmd commands and parameters (*continued*)**

| Command                   | Function                                                                                                                                                                | Parameters                                                                                                                                                                                                                                      |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sndCmdNoteOn</code> | Initiates a MIDI-defined tone. <code>SndDoCmd</code> returns immediately while the tone plays in the background. Subsequent sound playback requests interrupt the tone. | <p><code>param1</code> is the tone's pitch given as a MIDI key number in the range [0, 127].</p> <p><code>param2</code> is the tone's duration in milliseconds</p> <p><code>param3</code> is its amplitude given as MIDI velocity [0, 127].</p> |
| <code>sndCmdQuiet</code>  | Stops the playback of the currently generated tone.                                                                                                                     | All parameter values are ignored.                                                                                                                                                                                                               |

**Compatibility** Commands other than `sndCmdFreqDurationAmp` are implemented in Palm OS 3.0 and later. In OS versions earlier than 3.0, `SndDoCmd` will crash with a fatal error if you pass a command other than `sndCmdFreqDurationAmp`.

**See Also** [SndPlaySmf\(\)](#)

## SndGetDefaultVolume Function

**Purpose** Return volume levels cached by the Sound Manager.

**Declared In** `SoundMgr.h`

**Prototype** `void SndGetDefaultVolume (UInt16 *alarmAmpP, UInt16 *sysAmpP, UInt16 *masterAmpP)`

**Parameters**

- ← *alarmAmpP*  
Pointer to the alarm amplitude.
- ← *sysAmpP*  
Pointer to the system sound amplitude.
- ← *masterAmpP*  
Pointer to the master amplitude.

**Comments** Pass `NULL` for those settings that you don't care about.

## Sound Manager

### *SndInterruptSmfIrregardless*

---

**Compatibility** Never call this function in Palm OS 5. To retrieve default volume levels, you should ask for the user's preferences settings.

**See Also** [SndSetDefaultVolume\(\)](#)

## SndInterruptSmfIrregardless Function

**Purpose** Stop the currently playing MIDI file, even if the performance was declared to be intolerant of interruptions.

**Declared In** `SoundMgr.h`

**Prototype** `Err SndInterruptSmfIrregardless (void)`

**Returns** Always returns `errNone`.

**Compatibility** Implemented in Palm OS 4.0 and later.

**See Also** [SndPlaySmf\(\)](#), [SndPlaySmfResourceIrregardless\(\)](#)

## SndPlaySmf Function

**Purpose** Perform a Standard MIDI File, or returns the duration of the file.

**Declared In** `SoundMgr.h`

**Prototype** `Err SndPlaySmf (void *channelP,  
SndSmfCmdEnum command, UInt8 *midiDataP,  
SndSmfOptionsType *optionsP,  
SndSmfChanRangeType *channelRangeP,  
SndSmfCallbacksType *callbacksP,  
Boolean noWait)`

**Parameters** → *channelP*

A pointer to the sound channel on which you want to perform the MIDI file. Pass NULL for the "shared" sound channel.

---

**IMPORTANT:** The Sound Manager only supports one channel of sound synthesis: You must pass NULL as the value of `channel`.

---

→ *command*

One of the [SndPlaySmf Commands](#): either `SndSmfCmdPlay` (play the file) or `SndSmfCmdDuration` (return the duration of the file in milliseconds).

→ *mididataP*

The MIDI data; this can point to an [SndMidiRecHdrType](#) structure, or it can point directly to the actual MIDI data bytes in memory.

→ *optionsP*

A pointer to a [SndSmfOptionsType](#) structure that defines performance parameters, such as volume, starting offset, and interruption tolerance. For default behavior, pass `NULL`. For more information, including default settings, see [SndSmfOptionsType](#).

→ *channelRangeP*

A pointer to a [SndSmfChanRangeType](#) structure that specifies the range of MIDI channels (in the SMF data) to use during playback. To play all channels, pass `NULL`.

→ *callbacksP*

A pointer to a [SndSmfCallbacksType](#) structure that holds your callback functions. Pass `NULL` if you don't want any callbacks.

*noWait*

This value is ignored. This function always finishes playing the SMF selection before returning (but see the Comments section, below).

**Returns** Returns `errNone` if the operation completed successfully, or one of the following if there was an error:

`sndErrBadParam`

Invalid value passed to this function.

`sndErrBadChannel`

Invalid sound channel.

`sndErrMemory`

Insufficient memory.

`sndErrOpen`

Tried to open channel that's already open.

## Sound Manager

### *SndPlaySmf*

---

`sndErrQFull`

Can't accept more notes.

`sndErrFormat`

Unsupported data format.

`sndErrBadStream`

Invalid data stream.

`sndErrInterrupted`

Play was interrupted.

#### **Comments**

Although this call is always synchronous, you can register a “blocking” function that’s called periodically as the MIDI file is playing. See [SndBlockingFuncType\(\)](#) for more information.

Normally, playback is halted by events generated by user interaction with the screen, digitizer, or hardware-based buttons. You can override this behavior by setting the `interruptible` field of the `optionsP` argument to `false`.

This function waits until any currently-playing simple sound has finished before starting playback of the requested MIDI data. A similar function, [SndPlaySmfIrregardless\(\)](#), doesn’t wait: it interrupts the current performance and immediately begins playback of the requested data.

#### **Compatibility**

Implemented in Palm OS 3.0 and later.

## SndPlaySmfIrregardless Function

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Like <a href="#">SndPlaySmf()</a> , but interrupts any currently playing simple sound, regardless of that sound's declared interruption tolerance.                                                                                                        |
| <b>Declared In</b> | SoundMgr.h                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err SndPlaySmfIrregardless (void *channelP,<br/>    SndSmfCmdEnum command, UInt8 *midiDataP,<br/>    SndSmfOptionsType *optionsP,<br/>    SndSmfChanRangeType *channelRangeP,<br/>    SndSmfCallbacksType *callbacksP,<br/>    Boolean noWait)</pre> |
| <b>Parameters</b>  | <p>→ <i>channelP</i></p> <p>A pointer to the sound channel on which you want to perform the MIDI file. Pass NULL for the “shared” sound channel.</p>                                                                                                      |

---

**IMPORTANT:** The Sound Manager only supports one channel of sound synthesis: You must pass NULL as the value of *channel*.

---

- *command*
- One of the [SndPlaySmf Commands](#): either `SndSmfCmdPlay` (play the file) or `SndSmfCmdDuration` (return the duration of the file in milliseconds).
- *midiDataP*
- The MIDI data; this can point to an [SndMidiRecHdrType](#) structure, or it can point directly to the actual MIDI data bytes in memory.
- *optionsP*
- A pointer to a [SndSmfOptionsType](#) structure that defines performance parameters, such as volume, starting offset, and interruption tolerance. For default behavior, pass NULL. For more information, including default settings, see [SndSmfOptionsType](#).
- *channelRangeP*
- A pointer to a [SndSmfChanRangeType](#) structure that specifies the range of MIDI channels (in the SMF data) to use during playback. To play all channels, pass NULL.

→ *callbacksP*

A pointer to a [SndSmfCallbacksType](#) structure that holds your callback functions. Pass NULL if you don't want any callbacks.

*noWait*

This value is ignored. This function always finishes playing the SMF selection before returning.

**Returns** Returns `errNone` if the operation completed successfully, or one of the following if there was an error:

`sndErrBadParam`

Invalid value passed to this function.

`sndErrBadChannel`

Invalid sound channel.

`sndErrMemory`

Insufficient memory.

`sndErrOpen`

Tried to open channel that's already open.

`sndErrQFull`

Can't accept more notes.

`sndErrFormat`

Unsupported data format.

`sndErrBadStream`

Invalid data stream.

`sndErrInterrupted`

Play was interrupted.

**Comments** Although this call is always synchronous, you can register a "blocking" function that's called periodically as the MIDI file is playing. See [SndBlockingFuncType\(\)](#) for more information.

Normally, playback is halted by events generated by user interaction with the screen, digitizer, or hardware-based buttons. You can override this behavior by setting the `interruptible` field of the `optionsP` argument to `false`.

This function doesn't wait for any currently-playing simple sound to finish before starting playback of the requested MIDI data: it interrupts the current performance and immediately begins playback of the requested data. A similar function, [SndPlaySmf\(\)](#),

waits for any currently-playing simple sound to finish before starting playback of the requested MIDI data.

**Compatibility** Implemented in Palm OS 4.0 and later.

## **SndPlaySmfResource Function**

**Purpose** Play a MIDI track read out of an open resource database.

**Declared In** `SoundMgr.h`

**Prototype** `Err SndPlaySmfResource (UInt32 resType,  
Int16 resID, SystemPreferencesChoice volume)`

**Parameters**

- *resType*  
SMF resource type.
- *resID*  
SMF resource ID.
- *volume*  
Volume setting; one of `prefSysSoundVolume`, `prefGameSoundVolume`, or `prefAlarmSoundVolume` (all defined in `Preferences.h`).

**Returns** Returns `errNone` if the track was played successfully, or one of the following if an error occurred:

`sndErrBadParam`  
The `volumeSelector` parameter is invalid or the SMF resource has invalid data.

`dmErrCantFind`  
The specified resource doesn't exist.

*other values*  
See [SndPlaySmf\(\)](#)

**Comments** This function plays the entire MIDI file using all MIDI channels. Playback is interrupted by a key down or digitizer event. No callbacks are specified.

This function waits until any currently playing simple sound has finished before starting playback of the requested MIDI data. A similar function, [SndPlaySmfResourceIrregardless\(\)](#), doesn't wait: It interrupts the current performance and immediately begins playback of the requested data.

**Compatibility**    Implemented in Palm OS 3.2 and later.

## **SndPlaySmfResourceIrregardless Function**

- Purpose**    Like [SndPlaySmfResource\(\)](#), but interrupts any currently playing simple sound, regardless of that sound's declared tolerance for interruption.
- Declared In**    `SoundMgr.h`
- Prototype**    `Err SndPlaySmfResourceIrregardless (`  
                  `UInt32 resType, Int16 resID,`  
                  `SystemPreferencesChoice volumeSelector)`
- Parameters**    `→ resType`  
                  SMF resource type.
- `→ resID`  
                  SMF resource ID.
- `→ volume`  
                  Volume setting; one of `prefSysSoundVolume`, `prefGameSoundVolume`, or `prefAlarmSoundVolume`.
- Returns**    Returns `errNone` if the track was played successfully, or one of the following if an error occurred:
- `sndErrBadParam`  
                  The `volumeSelector` parameter is invalid or the SMF resource has invalid data.
- `dmErrCantFind`  
                  The specified resource doesn't exist.
- other values*  
                  See [SndPlaySmf\(\)](#)
- Comments**    This function plays the entire MIDI file using all MIDI channels. Playback is interrupted by a key down or digitizer event. No callbacks are specified.
- This function doesn't wait for any currently playing simple sound to finish before starting playback of the requested MIDI data: it interrupts the current performance and immediately begins playback of the requested data. A similar function, [SndPlaySmfResource\(\)](#), does wait.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## **SndPlaySystemSound Function**

**Purpose**            Play a pre-defined (simple) system sound.

**Declared In**      `SoundMgr.h`

**Prototype**        `void SndPlaySystemSound (SndSysBeepType beepID)`

**Parameters**       `→ beepID`  
                      One of the system beep sound constants defined in the [System Beeps](#) enum.

**Comments**        If you're playing an alarm (`sndAlarm`), the user's alarm volume preference setting is used. For all other system sounds, the system volume preference is used.

                      Alarm sounds (`sndAlarm`) are played synchronously: `SndPlaySystemSound` blocks until the sound has been played. All other sounds are played asynchronously.

## **SndSetDefaultVolume Function**

**Purpose**            Set the default sound volume levels cached by the Sound Manager.

**Declared In**      `SoundMgr.h`

**Prototype**        `void SndSetDefaultVolume (UInt16 *alarmAmpP,  
                              UInt16 *sysAmpP, UInt16 *masterAmpP)`

**Parameters**       `→ alarmAmpP`  
                      Pointer to the alarm amplitude.

`→ sysAmpP`  
                      Pointer to the system sound amplitude.

`→ masterAmpP`  
                      Pointer to the master amplitude.

**Returns**           Returns nothing.

**Comments**        Any of the arguments may be NULL. In that case, the corresponding setting is not altered.

## Sound Manager

### Simple Sound Application-Defined Functions

---

**Compatibility** Never call this function in Palm OS 5.

**See Also** [SndGetDefaultVolume\(\)](#)

## Simple Sound Application-Defined Functions

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | A callback function that is invoked periodically during SMF playback.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | SoundMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | Boolean SndBlockingFuncType (void *channelP,<br>UInt32 userData, Int32 time)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>channelP</i><br/>A pointer to the sound channel on which the file is being played. Currently always NULL.</p> <p>→ <i>userData</i><br/>Application-defined data that's specified when the callback function is registered.</p> <p>→ <i>time</i><br/>The amount of time, in milliseconds, available for completion of this function.</p>                                                                                                                                                                                                                                                                        |
| <b>Returns</b>     | Return true from your callback if playback is to continue. Return false if playback is to be aborted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Comments</b>    | <p>Your application's blocking callback is called whenever the MIDI parser is "between notes." Your application can do whatever it wants during this period, as long as it doesn't take more than <i>time</i> milliseconds.</p> <p>Specify your blocking callback function using the <i>blocking</i> field of the <a href="#">SndSmfCallbacksType</a> structure that you pass to <a href="#">SndPlaySmf()</a>. Note that the <i>blocking</i> field is a <a href="#">SndCallbackInfoType</a> structure; it contains a pointer to your callback function and a 32-bit value that is passed, as-is, to your callback.</p> |
| <b>See Also</b>    | <a href="#">SndComplFuncType()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## SndComplFuncType Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | A callback function that is invoked immediately after a MIDI file (SMF) finishes playing.                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Prototype</b>   | <code>void SndComplFuncType (void* channelP,<br/>                          UInt32 userData)</code>                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p>→ <i>channelP</i><br/>A pointer to the sound channel on which the file was played; currently always NULL.</p> <p>→ <i>userData</i><br/>Application-defined data that's specified when the callback function is registered.</p>                                                                                                                                                                |
| <b>Comments</b>    | Specify your blocking callback function using the <code>completion</code> field of the <a href="#">SndSmfCallbacksType</a> structure that you pass to <a href="#">SndPlaySmf()</a> . Note that the <code>completion</code> field is a <a href="#">SndCallbackInfoType</a> structure; it contains a pointer to your callback function and a 32-bit value that is passed, as-is, to your callback. |

## Sampled Sound Data Structures

### SndFormatType Typedef

|                  |                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>   | Data type used to contain the encoding format of the data that you propose to pour through the stream with <a href="#">SndStreamCreateExtended()</a> . See “ <a href="#">Sound Data Encoding Formats</a> ” on page 851 for the set of values that this type can contain. |
| <b>Prototype</b> | <code>typedef UInt32 SndFormatType;</code>                                                                                                                                                                                                                               |

### SndPtr Typedef

|                |                                                                                           |
|----------------|-------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Type used to cast a pointer to the sound data used by <a href="#">SndPlayResource()</a> . |
|----------------|-------------------------------------------------------------------------------------------|

## Sound Manager

### *SndSampleType*

---

- Prototype** `typedef void *SndPtr;`
- Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

### **SndSampleType Typedef**

- Purpose** Data type used to specify the sample format (size, data type, endianness) of a sampled sound stream. Used by [SndStreamCreate\(\)](#). See “[SndSampleTag](#)” on page 852 for the set of values that this type can contain.
- Prototype** `typedef Enum16 SndSampleType;`
- Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

### **SndStreamMode Typedef**

- Purpose** Data type used to specify the “direction” (input or output) of a sampled sound stream. Used by the [SndStreamCreate\(\)](#) function. See “[SndStreamModeTag](#)” on page 854 for the set of values that this type can contain.
- Prototype** `typedef Enum8 SndStreamMode;`
- Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

### **SndStreamRef Typedef**

- Purpose** Data type that represents a sampled stream. You create an `SndStreamRef` with [SndStreamCreate\(\)](#).
- Prototype** `typedef UInt32 SndStreamRef;`
- Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

### **SndStreamWidth Typedef**

- Purpose** Data type that specifies whether a sampled data stream is in stereo or mono. This data type is used by the [SndStreamCreate\(\)](#) function. See “[SndStreamWidthTag](#)” on page 855 for the set of values that this type can contain.

**Prototype**    `typedef Enum8 SndStreamWidth;`  
**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## Sampled Sound Constants

### Sound Stream Feature Constants

To detect the presence of the [Sound Stream Feature Set](#) you check for the Sound Manager's version number feature. If the Sound Manager's version feature is defined, the Sound Stream feature set is supported.

| Constant                      | Value | Description                                                                                                                                                                       |
|-------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sndFtrIDVersion</code>  | 0     | The feature number to supply to <a href="#">FtrGet()</a> , along with a creator ID of <code>sysFileCSoundMgr</code> , when attempting to obtain the version of the Sound Manager. |
| <code>sndMgrVersionNum</code> | (100) | The current version of the Sound Manager.                                                                                                                                         |

### Sound Data Encoding Formats Enum

**Purpose**    The `SndFormatTag` enum defines a set of constants that represent various sound data encoding formats. Pass one of these constants as the `encodingFormat` argument to [SndStreamCreateExtended\(\)](#).

**Prototype**

```
enum SndFormatTag {  
    sndFormatPCM = 0,  
    sndFormatIMA_ADPCM = 'APCM',  
    sndFormatDVI_ADPCM = 'DPCM',  
    sndFormatMP3 = 'MPG3',  
    sndFormatAAC = 'DAAC',  
    sndFormatOGG = 'OGGV'  
}
```

## Sound Manager

### *SndSampleTag*

---

#### Value Descriptions

|                                 |                                                                                                                                                                                                 |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sndFormatPCM</code>       | Pulse Code Modulation format. This is the “no encoding” format; the data is a series of samples that are linear with regard to amplitude quantization and regular with regard to sampling rate. |
| <code>sndFormatIMA_ADPCM</code> | The Interactive Multimedia Association’s implementation of “adaptive delta” encoding. The sampling rate is constant, but the quantization is non-linear.                                        |
| <code>sndFormatDVI_ADPCM</code> | Microsoft’s adaptive delta implementation. This is the same as IMA ADPCM.                                                                                                                       |
| <code>sndFormatMP3</code>       | Motion Picture Group Audio Layer III.                                                                                                                                                           |
| <code>sndFormatAAC</code>       | Dolby Advanced Audio Coding.                                                                                                                                                                    |
| <code>sndFormatOGG</code>       | OGG Vorbis encoding.                                                                                                                                                                            |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present. The Palm OS 5 implementation of [SndStreamCreateExtended\(\)](#) supports `sndFormatPCM` data only. To play ADPCM data, use [SndPlayResource\(\)](#).

## SndSampleTag Enum

**Purpose** The `SndSampleTag` enum defines a set of constants that represent the sample format (size, data type, endianness) of a sampled sound stream. These constant values are used with [SndStreamCreate\(\)](#). The lower four bits of these constants gives the size (in bytes) of a single sample, as shown here:

---

```
UInt8 byteSize = formatConstant & 0x0f
```

---

**Prototype**

```
enum SndSampleTag {  
    sndInt8 = 0x01,  
    sndUInt8 = 0x11,  
    sndInt16Big = 0x02,
```

```

    sndInt16Little = 0x12,
    sndInt32Big = 0x04,
    sndInt32Little = 0x14,
    sndFloatBig = 0x24,
    sndFloatLittle = 0x34,
#if CPU_ENDIAN == CPU_ENDIAN_BIG
    sndInt16 = sndInt16Big,
    sndInt16Opposite = sndInt16Little,
    sndInt32 = sndInt32Big,
    sndInt32Opposite = sndInt32Little,
    sndFloat = sndFloatBig,
    sndFloatOpposite= sndFloatLittle
#else
    sndInt16 = sndInt16Little,
    sndInt16Opposite = sndInt16Big,
    sndInt32 = sndInt32Little,
    sndInt32Opposite= sndInt32Big,
    sndFloat = sndFloatLittle,
    sndFloatOpposite= sndFloatBig
#endif
}

```

### Value Descriptions

|                               |                                                                              |
|-------------------------------|------------------------------------------------------------------------------|
| <code>sndFloat</code>         | Signed floating-point data in the device's native endianness.                |
| <code>sndFloatBig</code>      | Signed floating-point data in big-endian format.                             |
| <code>sndFloatLittle</code>   | Signed floating-point data in little-endian format.                          |
| <code>sndFloatOpposite</code> | Signed floating-point data in the endianness opposite to that of the device. |
| <code>sndInt16</code>         | Signed 16-bit integer data in the device's native endianness.                |
| <code>sndInt16Big</code>      | Signed 16-bit integer data in big-endian format.                             |

## Sound Manager

### *SndStreamModeTag*

---

|                               |                                                                              |
|-------------------------------|------------------------------------------------------------------------------|
| <code>sndInt16Little</code>   | Signed 16-bit integer data in little-endian format.                          |
| <code>sndInt16Opposite</code> | Signed 16-bit integer data in the endianness opposite to that of the device. |
| <code>sndInt32</code>         | Signed 32-bit integer data in the device's native endianness.                |
| <code>sndInt32Big</code>      | Signed 32-bit integer data in big-endian format.                             |
| <code>sndInt32Little</code>   | Signed 32-bit integer data in little-endian format.                          |
| <code>sndInt32Opposite</code> | Signed 32-bit integer data in the endianness opposite to that of the device. |
| <code>sndInt8</code>          | Signed 8-bit data.                                                           |
| <code>sndUInt8</code>         | Unsigned 8-bit data.                                                         |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present. In Palm OS 5, the 32-bit and floating point formats aren't supported.

## SndStreamModeTag Enum

**Purpose** The `SndStreamModeTag` enum defines constants that represent the "direction" (input or output) of a sampled sound stream. Use these constants with the [SndStreamCreate\(\)](#) function.

**Prototype**

```
enum SndStreamModeTag {  
    sndInput,  
    sndOutput  
}
```

### Value Descriptions

|                        |                                  |
|------------------------|----------------------------------|
| <code>sndInput</code>  | Input stream used for recording. |
| <code>sndOutput</code> | Output stream used for playback. |

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamWidthTag Enum

**Purpose**    The SndStreamWidthTag defines constants that represent mono and stereo sampled data streams. Use these constants with the [SndStreamCreate\(\)](#) function.

**Prototype**

```
enum SndStreamWidthTag {  
    sndMono,  
    sndStereo  
}
```

### Value Descriptions

|           |                              |
|-----------|------------------------------|
| sndMono   | Mono (one channel) stream.   |
| sndStereo | Stereo (two channel) stream. |

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## Sound Resource Playback Flags

Use these flags when calling [SndPlayResource\(\)](#) to specify various settings. Currently, the only setting is function synchronization.

| Constant      | Value       | Description                                                                                                                                                                           |
|---------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sndFlagSync   | 0x00000000  | Tells SndPlayResource to wait until all sound data has been fed to the DAC before returning (meaning that the function will return just a bit before the sound has finished playing). |
| sndFlagAsync  | 0x00000001  | Tells SndPlayResource to return immediately while playback continues in a separate thread.                                                                                            |
| sndFlagNormal | sndFlagSync | A shorthand for the set of “normal” flag settings.                                                                                                                                    |

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## Stereo Pan Constants

These constants define the extremes and the midpoint when altering the stream's stereo balance with [SndStreamSetPan\(\)](#). SndStreamSetPan allows you to set the balance to one of these values, or any integral value between sndPanFullLeft and sndPanFullRight.

| Constant        | Value   | Description                                           |
|-----------------|---------|-------------------------------------------------------|
| sndPanCenter    | (0)     | The stereo balance is centered.                       |
| sndPanFullLeft  | (-1024) | The stereo balance is panned completely to the left.  |
| sndPanFullRight | (1024)  | The stereo balance is panned completely to the right. |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## Volume Constants Enum

**Purpose** Use the volume constants defined in this enum with [SndStreamSetVolume\(\)](#) and [SndPlayResource\(\)](#). The constants tell the functions to retrieve the named sound volume preference (as set by the user) and apply it as a volume setting.

**Prototype**

```
enum {  
    sndSystemVolume = -1,  
    sndGameVolume = -2,  
    sndAlarmVolume = -3  
}
```

### Value Descriptions

|                 |                                     |
|-----------------|-------------------------------------|
| sndSystemVolume | The user's system sound preference. |
| sndGameVolume   | The user's game sound preference.   |
| sndAlarmVolume  | The uer's alarm sound preference.   |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## Sampled Sound Functions

### SndPlayResource Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Play formatted sound data read from a resource or file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <code>Err SndPlayResource (SndPtr soundP, Int32 volume, UInt32 flags)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p>→ <i>soundP</i><br/>A pointer to the beginning of the formatted sound (including the header). Currently, only WAVE data is recognized (see the Comments section, below); in this case, <i>soundP</i> must point to the “RIFF” ID (byte 0 in a simple .wav file).</p> <p>→ <i>volume</i><br/>Amplitude scalar, in the range [0, 32k]. See <a href="#">SndStreamSetVolume()</a> for information on how amplitude scalar values are applied.</p> <p>→ <i>flags</i><br/>One of the “<a href="#">Sound Resource Playback Flags</a>” on page 855. Currently, the only setting is function synchronization: use <code>sndFlagSync</code> to have the function wait until all sound data has been fed to the DAC before returning, or <code>sndFlagAsync</code> flag to have the function return immediately while playback continues in a separate thread.</p> |
| <b>Returns</b>     | <p>Returns <code>errNone</code> if the operation completed successfully, or one of the following if there was an error:</p> <p><code>sndErrBadParam</code><br/>The specified resource or file contains no data.</p> <p><code>sndErrFormat</code><br/>The data is in an unsupported format.</p> <p><code>sndErrMemory</code><br/>The function couldn’t allocate sufficient memory.</p> <p><i>other errors</i><br/>The device couldn’t allocate system resources for the sound.</p>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>    | The supported WAVE parameters are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Sound Manager

### *SndStreamCreate*

---

- Uncompressed (PCM) or IMA 4-bit adaptive differential (IMA ADPCM). The ADPCM type is also known as DVI ADPCM; in a WAVE file, it's known as format 0x11.
- One or two-channels
- All normal sampling rates (8k, 11k, 22.05k, 44.1k, 48, 96k).

You can't interrupt or abort a resource playback once it's been initiated. The resource always plays to the end of the data.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamCreate Function

**Purpose** Create a new audio data stream that can be used to record or play back uncompressed, sampled audio data.

**Declared In** `SoundMgr.h`

**Prototype**

```
Err SndStreamCreate (SndStreamRef *streamP,  
                    SndStreamMode mode, UInt32 sampleRate,  
                    SndSampleType type, SndStreamWidth width,  
                    SndStreamBufferCallback callback,  
                    void *callbackArgP, UInt32 bufferSize,  
                    Boolean callbackIsARM)
```

**Parameters**

- ← *streamP*  
Token that represents the newly created stream.
- *mode*  
One of the [SndStreamModeTag](#) constants that represents the “direction” of the data stream. Either `sndInput` (for recording), or `sndOutput` (for playback).
- *sampleRate*  
Sampling rate, in frames-per-second. Specify the native rate of the data, such as 22050, 44100, or 48000. The maximum rate is 96000.
- *type*  
Sample quantization and endianness (but see the section on “[Data Formats](#),” below). Supply one of the values documented under “[SndSampleTag](#)” on page 852.

→ *width*

One of the constants documented under “[SndStreamWidthTag](#)” on page 855 that represents the number of channels of data in the stream.

→ *callback*

A callback function that gets called when another buffer is needed. See [SndStreamBufferCallback\(\)](#) for a description of the callback function that you must implement.

→ *callbackArgP*

Caller-defined data that gets passed to callback.

→ *bufferSize*

Preferred size (in frames) for the buffers that are passed to callback. Note that the actual buffer size (as allocated by the Sound Manager) may be different from this request.

→ *callbackIsARM*

Pass true if the callback function is written in ARM-native code, or false if it is written in 68k code.

**Returns** Returns `errNone` if the operation completed successfully, or one of the following if there was an error:

`sndErrBadParam`

`streamP` is invalid, `callback` is NULL, the sampling rate is too high (greater than 96000), or the device doesn’t like some other sound parameter value.

`sndErrorMemory`

All streams are being used (there is a maximum of 16), or memory for this stream couldn’t otherwise be allocated.

*other errors*

The device couldn’t allocate system resources for the stream.

**Comments** This function creates a new audio stream into which you can write (playback) or from which you can read (record) buffers of uncompressed, sampled audio data. The stream’s “direction”—whether it will be used for recording or playback—is described by the mode argument.

You can create one input stream and as many as 15 output streams. The “active” end of a stream is hardwired to read from or write to the device’s sound driver. This means you can’t “redirect” an input

stream to read from a file (for example), nor can you connect one output stream to another output stream in an attempt to create a filter chain. You can, however, collect data from the input stream, manipulate it, and then write it to an output stream.

### Data Formats

The format of the data that flows through the stream is described by the `sampleRate`, `type`, and `width` arguments. If you're using an "extended" stream (see [SndStreamCreateExtended\(\)](#)), you can also declare the data's encoding.

If you look at the [SndSampleTag](#) constants, you'll see four flavors for each quantization type: a big-endian version, a little-endian version, a native-endian version (defined as one of the other two), and an "opposite" version, which has endianness opposite that of the native version. In general, you should use the native-endian version when choosing a value for the `type` parameter. The one exception to this (in Palm OS 5) is if your application is written for 68k, but uses an ARM callback function (i.e. `callbackIsARM == true`). In this case you should use one of the little-endian formats as the `type` value when you create your stream.

### Running the Stream

The new stream starts running when you pass the `stream` token returned by this function to the [SndStreamStart\(\)](#) function. This initiates a series of calls to your `callback` function, which is where the action is: Each `callback` invocation is passed a buffer into which you write or from which you read a chunk of audio data. The `callback` function is also passed the `callbackArg` that you supply here. See [SndStreamBufferCallback\(\)](#) for more information on the callback function.

### Buffering and Latency

Currently, audio streams are double-buffered. With regard to playback, this means that while one buffer (buffer A) is being played, your callback function is placing data in the other buffer (B). When A is "empty," the Sound Manager seamlessly starts playing buffer B, and passes buffer A back to your callback; when B is empty, it starts playing A, and passes back B, and so on. It's important that your `callback` function fills the data buffers as

quickly as possible—certainly no longer than it takes to play a buffer of data. This same double-buffer scheme is also applied to sound recording although, of course, for recording you’re emptying each buffer (and doing something with the data) in your callback function.

Regarding latency, you can use the `bufferSize` argument to suggest a buffer size and thereby increase or decrease latency, but you can’t change the number of buffers. Keep in mind that the actual buffer size that’s used may not be the same as the size you suggest; hardware and memory limitations may enforce a maximum or minimum buffer size. Also keep in mind that the `bufferSize` is measures in frames (not bytes).

**See Also**    [SndStreamStart\(\)](#), [SndStreamDelete\(\)](#),  
[SndStreamBufferCallback\(\)](#)

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamCreateExtended Function

**Purpose**    Create a new audio data stream that can be used to record or play back audio data.

**Declared In**    `SoundMgr.h`

**Prototype**    `Err SndStreamCreate (SndStreamRef *streamP,  
                             SndStreamMode mode,  
                             SndFormatType encodingFormat,  
                             UInt32 sampleRate, SndSampleType type,  
                             SndStreamWidth width,  
                             SndStreamVariableBufferCallback callback,  
                             void *callbackArgP, UInt32 bufferSize,  
                             Boolean callbackIsARM)`

**Parameters**     $\leftarrow streamP$   
                    Token that represents the newly created stream.  
  
                     $\rightarrow mode$   
                    One of the [SndStreamModeTag](#) constants that represents the “direction” of the data stream. Either `sndInput` (for recording), or `sndOutput` (for playback).

## Sound Manager

### *SndStreamCreateExtended*

---

→ *encodingFormat*

Constant that represents the encoding format of the data that you propose to pour through the stream. See [SndFormatType](#) for a list of eligible values. Currently, only `sndFormatPCM` is supported.

→ *sampleRate*

Sampling rate, in frames-per-second. Specify the native rate of the data, such as 22050, 44100, or 48000. The maximum rate is 96000.

→ *type*

Sample quantization and endianness (see “[Data Formats](#)” on page 860 for advice on choosing this value). Supply one of the values documented under “[SndSampleTag](#)” on page 852.

→ *width*

One of the constants documented under “[SndStreamWidthTag](#)” on page 855 that represents the number of channels of data in the stream.

→ *callback*

A callback function that gets called when another buffer of data is needed. As implied by the name of the data type, the function accepts variable-sized buffers. See [SndStreamVariableBufferCallback\(\)](#) for a description of the callback function that you must implement.

→ *callbackArgP*

Caller-defined data that gets passed to callback.

→ *bufferSize*

Preferred size (in frames) for the buffers that are passed to callback. Note that the actual buffer size (as allocated by the Sound Manager) may be different from this request.

→ *callbackIsARM*

Pass `true` if the callback function is written in ARM-native code, or `false` if it is written in 68k code.

**Returns** Returns `errNone` if the operation completed successfully, or one of the following if there was an error:

`sndErrBadParam`

`streamP` is invalid, `callback` is NULL, the sampling rate is too high (greater than 96000), or the device doesn't like some other sound parameter value.

`sndErrorMemory`

All streams are being used (there is a maximum of 16), or memory for this stream couldn't otherwise be allocated.

*other errors*

The device couldn't allocate system resources for the stream.

### Comments

With a few minor exceptions, this function is equivalent to [SndStreamCreate\(\)](#); see that function's Comments section for a description of how the stream creation functions generally work.

One difference between standard and extended streams: If you're using an extended stream, you can also declare the data's encoding. When selecting that encoding, be aware of the following:

- The data format that you specify for an input stream must match the data that's produced by the audio hardware.
- For an output stream, you can specify any of the formats that the Sound Manager supports; the data is automatically converted to the output hardware's native audio format. Whether your stream's format setting actually affects the hardware is undefined. For example, if you set an output stream to use a 48k sampling rate, that doesn't mean that the DAC will be set to 48k.
- Currently, only `sndFormatPCM` is supported.

Extended streams also allow for variable-sized buffers, as opposed to the fixed-sized buffers used by `SndStreamCreate`. This enables support for variable-length encoded data (such as MP3). To accommodate the variable-sized buffer, the callback function's prototype changes slightly for an extended stream: see [SndStreamVariableBufferCallback\(\)](#) for a full description of the callback function you use with `SndStreamCreateExtended`.

## **SndStreamDelete Function**

|                      |                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Stop the stream and destroy it.                                                                                                                               |
| <b>Declared In</b>   | SoundMgr.h                                                                                                                                                    |
| <b>Prototype</b>     | Err SndStreamDelete (SndStreamRef stream)                                                                                                                     |
| <b>Parameters</b>    | → <i>stream</i><br>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a> .                            |
| <b>Returns</b>       | Returns errNone if the operation completed successfully. Returns sndErrBadParam if the stream argument is invalid.                                            |
| <b>Comments</b>      | SndStreamDelete calls <a href="#">SndStreamStop()</a> before destroying the stream. You should never call SndStreamDelete from within your callback function. |
| <b>Compatibility</b> | Implemented if <a href="#">Sound Stream Feature Set</a> is present.                                                                                           |

## **SndStreamGetPan Function**

|                      |                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Retrieve a stream's stereo balance.                                                                                                                                                                                                            |
| <b>Declared In</b>   | SoundMgr.h                                                                                                                                                                                                                                     |
| <b>Prototype</b>     | Err SndStreamGetPan (SndStreamRef stream,<br>Int32 *panP)                                                                                                                                                                                      |
| <b>Parameters</b>    | → <i>stream</i><br>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a> .<br><br>← <i>panP</i><br>Pan value in the range [-1024 (hard left), 1024 (hard right)]. Center balance is 0. |
| <b>Returns</b>       | Returns errNone if the operation completed successfully. Returns sndErrBadParam if stream is invalid or panP is NULL.                                                                                                                          |
| <b>Compatibility</b> | Implemented if <a href="#">Sound Stream Feature Set</a> is present.                                                                                                                                                                            |

## SndStreamGetVolume Function

|                      |                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Retrieve the amplitude scalar for a sound stream.                                                                                                                                                                                                                             |
| <b>Declared In</b>   | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                       |
| <b>Prototype</b>     | <code>Err SndStreamGetVolume (SndStreamRef stream,<br/>Int32 *volumeP)</code>                                                                                                                                                                                                 |
| <b>Parameters</b>    | <p>→ <i>stream</i><br/>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a>.</p> <p>← <i>volumeP</i><br/>Amplitude scalar, in the range [0, 32k]. See <a href="#">SndStreamSetVolume()</a> for more information.</p> |
| <b>Returns</b>       | Returns <code>errNone</code> if the operation completed successfully. Returns <code>sndErrBadParam</code> if <i>stream</i> is invalid or <i>volumeP</i> is <code>NULL</code> .                                                                                                |
| <b>See Also</b>      | <a href="#">SndStreamSetVolume()</a>                                                                                                                                                                                                                                          |
| <b>Compatibility</b> | Implemented if <a href="#">Sound Stream Feature Set</a> is present.                                                                                                                                                                                                           |

## SndStreamPause Function

|                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Pause or resume a sample stream.                                                                                                                                                                                                                                       |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <code>Err SndStreamPause (SndStreamRef stream,<br/>Boolean pause)</code>                                                                                                                                                                                               |
| <b>Parameters</b>  | <p>→ <i>stream</i><br/>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a>.</p> <p>→ <i>pause</i><br/>If <code>true</code>, the function pauses the stream; if <code>false</code>, it resumes the stream</p> |
| <b>Returns</b>     | Returns <code>errNone</code> if the operation completed successfully (which includes the situation where the stream is already in the requested state). Returns <code>sndErrBadParam</code> if <i>stream</i> is invalid.                                               |
| <b>Comments</b>    | Currently, <code>SndStreamPause</code> simply calls <a href="#">SndStreamStop()</a> (if <i>pause</i> is <code>true</code> ) or <a href="#">SndStreamStart()</a> (if <i>pause</i> is <code>false</code> ). See                                                          |

## Sound Manager

### *SndStreamSetPan*

---

those functions for details about “pausing” and “resuming” a sound stream.

You can’t nest pauses; a single resume request is effective, regardless of the number of times the stream has been told to pause.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamSetPan Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sets a stream’s stereo balance.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <pre>Err SndStreamSetPan (SndStreamRef stream,<br/>                    Int32 pan);</pre>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>→ <i>stream</i></p> <p>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a>.</p> <p>→ <i>pan</i></p> <p>Pan value in the range [-1024 (full left), 1024 (full right)]. Center balance is 0. As a convenience, you can use the values described in “<a href="#">Stereo Pan Constants</a>.” Note that values outside of the valid range may yield unexpected results (but don’t generate an error).</p> |
| <b>Returns</b>     | Returns <code>errNone</code> if the operation completed successfully. Returns <code>sndErrBadParam</code> if <i>stream</i> is invalid.                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>    | The pan value is used as a scalar on a channel’s volume such that a channel increases from 0 (inaudible) to full volume as the pan value moves from an extreme to 0. Graphically, it looks like this:                                                                                                                                                                                                                                                             |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**See Also** [SndStreamGetPan\(\)](#)

## SndStreamSetVolume Function

**Purpose** Sets the amplitude scalar for a sound stream.

**Declared In** `SoundMgr.h`

**Prototype** `Err SndStreamSetVolume (SndStreamRef stream,  
 Int32 volume);`

**Parameters**  $\rightarrow$  *stream*

Stream token, as returned from [SndStreamCreate\(\)](#) or [SndStreamCreateExtended\(\)](#).

$\rightarrow$  *volume*

Amplitude scalar in the range [0, 32k]. Values less than 0 are converted to 1024 (unity gain).

**Returns** Returns `errNone` if the operation completed successfully. Returns `sndErrBadParam` if *stream* is invalid.

**Comments** The volume value is applied as an amplitude scalar on the samples that this stream's callback function produces. The scalar is in the range [0, 32k], where 1024 is unity gain (i.e. the samples are multiplied by 1.0). The mapping of *volume* to a scalar is linear; thus a volume of 512 scales the samples by  $\sim 0.5$ , 2048 scales by  $\sim 2.0$ , and so on.

## Sound Manager

### *SndStreamStart*

---

To specify a user preference volume setting, supply one of the constants documented under “[Volume Constants](#)” on page 856. These values are guaranteed to be less than unity gain.

If the stream is stereo, both channels are scaled by the same amplitude scalar. To adjust the balance between the channels, use [SndStreamSetPan\(\)](#).

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamStart Function

**Purpose** Start a sample stream running.

**Declared In** `SoundMgr.h`

**Prototype** `Err SndStreamStart (SndStreamRef stream)`

**Parameters** `→ stream`  
Stream token, as returned from [SndStreamCreate\(\)](#) or [SndStreamCreateExtended\(\)](#).

**Returns** Returns `errNone` if the operation completed successfully (`errNone` is returned even if the stream is already running). Returns `sndErrBadParam` if `stream` is invalid.

**Comments** If the stream is already running, `SndStreamStart` returns immediately (with `errNone`). If it isn’t running, the function starts the stream by initiating invocations of its callback function. If the stream is paused (through [SndStreamPause\(\)](#)), the stream is resumed.

You can call this function from within another stream’s callback function. This allows one stream to tell another stream to start playing.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## SndStreamStop Function

|                      |                                                                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Stop a sample stream from running.                                                                                                                                                                                                                                                                         |
| <b>Declared In</b>   | SoundMgr.h                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | Err SndStreamStop (SndStreamRef stream)                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | <p>→ <i>stream</i></p> <p>Stream token, as returned from <a href="#">SndStreamCreate()</a> or <a href="#">SndStreamCreateExtended()</a>.</p>                                                                                                                                                               |
| <b>Returns</b>       | <p>Returns errNone if the operation completed successfully (errNone is returned even if the stream is already stopped).</p> <p>Returns sndErrBadParam if stream is invalid.</p>                                                                                                                            |
| <b>Comments</b>      | <p>Stops a running sound stream by neglecting to call the stream's callback function. The stream remains in this suspended state until you call <a href="#">SndStreamStart()</a>.</p> <p>You can call this function from the stream's own callback function. In other words, a stream can stop itself.</p> |
| <b>Compatibility</b> | Implemented if <a href="#">Sound Stream Feature Set</a> is present.                                                                                                                                                                                                                                        |

## Sampled Sound Application-Defined Functions

### SndStreamBufferCallback Function

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | In input mode, delivers a data buffer to your application. In output mode, allows your application to supply the next buffer's worth of data.                                                                                     |
| <b>Declared In</b> | SoundMgr.h                                                                                                                                                                                                                        |
| <b>Prototype</b>   | Err (*SndStreamBufferCallback) (void *userDataP, SndStreamRef stream, void *bufferP, UInt32 frameCount);                                                                                                                          |
| <b>Parameters</b>  | <p>→ <i>userDataP</i></p> <p>Caller-defined data, as provided in the callbackArg parameter to <a href="#">SndStreamCreate()</a>.</p> <p>→ <i>stream</i></p> <p>Token that represents the stream to which this buffer belongs.</p> |

## Sound Manager

### *SndStreamBufferCallback*

---

→ *bufferP*

The data buffer.

→ *frameCount*

Number of sample frames the buffer contains.

**Returns** Currently, the return value is ignored.

**Comments** The `SndStreamBufferCallback` function that you create is invoked in input (recording) mode when the Sound Manager wants to deliver a new buffer of sound data to your application. In output (playback) mode, it is invoked when the Sound Manager needs another buffer of sound data. You associate your callback function with a given stream when you call [SndStreamCreate\(\)](#).

In input mode, your callback function should read the data from the data buffer. In output mode, your callback function should write data into the data buffer (and it must fill the entire buffer with data). In either case, you want to do this as quickly as possible to avoid data underflow.

Note that the arguments passed to your callback function tell you nothing about the format of the data. You can use the `userDataP` argument to pass this information into the function.

The callback function is executed in a task that's created and managed by the Sound Manager. Because of this, the function doesn't have access to the symbols that you create in your application. Again, use the `userDataP` argument if you need to pass pointers to your symbols.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**See Also** [SndStreamCreate\(\)](#),  
[SndStreamVariableBufferCallback\(\)](#)

## SndStreamVariableBufferCallback Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | In input mode, delivers a variable-length data buffer to your application. In output mode, allows your application to supply the next buffer's worth of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | <code>SoundMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Parameters</b>  | <p>→ <i>userDataP</i><br/>    Caller-defined data, as provided by the <code>callbackArg</code> parameter to <a href="#">SndStreamCreateExtended()</a>.</p> <p>→ <i>stream</i><br/>    Token that represents the stream that this buffer belongs to.</p> <p>→ <i>bufferP</i><br/>    The data buffer.</p> <p>↔ <i>bufferSizeP</i><br/>    Size of the buffer, in bytes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Returns</b>     | Currently, the return value is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | <p>The <code>SndStreamVariableBufferCallback</code> function that you create is invoked in input (recording) mode when the Sound Manager wants to deliver a new buffer of sound data to your application. In output (playback) mode, it is invoked when the Sound Manager needs another buffer of sound data. You associate your callback function with a given stream when you call <a href="#">SndStreamCreateExtended()</a>.</p> <p>In input mode, your callback function should read the data from the data buffer. In output mode, your callback function should write data into the data buffer and then reset <code>*bufferSizeP</code> to the amount of data that was actually written. Unlike <a href="#">SndStreamBufferCallback()</a>, your callback function is not required to fill the entire buffer with data. Moreover, the data that it writes to the buffer doesn't have to meet any other threshold or requirement—for example, the buffer doesn't have to represent a certain amount of playback time. This flexibility is provided in order to support variable-length encoded data (such as MP3).</p> |

## Sound Manager

### *SndStreamVariableBufferCallback*

---

Whether your callback is reading from the buffer or writing to it, it should do this as quickly as possible to avoid data underflow.

Note that the arguments passed to your callback function tell you nothing about the format of the data. You can use the `userDataP` argument to pass this information into the function.

The callback function is executed in a task that's created and managed by the Sound Manager. Because of this, the function doesn't have access to the symbols that you create in your application. Again, use the `userDataP` argument if you need to pass pointers to your symbols.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

# Standard IO

---

This chapter provides reference material for the standard IO API:

- [Standard IO Functions and Macros](#)
- [Standard IO Provider Functions](#)
- [Application-Defined Function](#)

The header files `StdIOPalm.h` and `StdIOProvider.h` declare the standard IO API. For more information on using the standard IO API, see the chapter “[Standard IO Applications](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Standard IO Functions and Macros

The macros and functions in this section enable standard IO.

### fgetc Macro

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Siofgetc()</a> to return the next character from the input stream.                                                                                                                    |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                                                                                |
| <b>Prototype</b>   | <code>#define fgetc (fs)</code>                                                                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>fs</i></p> <p>An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented.</p> |
| <b>Returns</b>     | The next character from the input stream. The return value <code>EOF</code> indicates an error occurred.                                                                                                |

### **fgets Macro**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Siofgets()</a> to return a string from the input stream.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | #define fgets (strP, maxChars, fs)                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <div><div>← <i>strP</i></div><div>A pointer to the returned string.</div><div>→ <i>maxChars</i></div><div>The number of characters to read from the input stream, plus one for the null terminator.</div><div>→ <i>fs</i></div><div>An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented.</div></div> |
| <b>Returns</b>     | A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns <code>NULL</code> .                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | The returned string is always terminated by a null character.                                                                                                                                                                                                                                                                                                                                                                 |

### **fprintf Macro**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Siofprintf()</a> to write formatted output to an output stream.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | #define fprintf (fs, formatP, ...)                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <div><div>→ <i>fs</i></div><div>An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented.</div><div>→ <i>formatP</i></div><div>A pointer to a format string that controls how subsequent arguments are converted for output.</div><div>→ ...</div><div>Zero or more parameters to be formatted as specified by the <code>formatP</code> string.</div></div> |

- Returns** Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.
- Comments** This function internally calls [StrVPrintf\(\)](#) to do the formatting. See that function for details on which format specifications are supported.

### fputc Macro

- Purpose** Calls [Siofputc\(\)](#) to write a character to the output stream.
- Declared In** StdIOPalm.h
- Prototype** #define fputc (c, fs)
- Parameters** → *c*  
A character to write to the output stream.
- *fs*  
An output stream to which to write the character. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.
- Returns** The character that was written. If an error occurs, the value EOF is returned.

### fputs Macro

- Purpose** Calls [Siofputs\(\)](#) to write a string to the output stream.
- Declared In** StdIOPalm.h
- Prototype** #define fputs (strP, fs)
- Parameters** → *strP*  
A pointer to the string to write.
- *fs*  
An output stream to which to write the string. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.
- Returns** Returns 0 on success and the value EOF on error.

**getchar Macro**

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Siofgetc()</a> to read the next character from the <code>stdin</code> input stream.    |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                 |
| <b>Prototype</b>   | <code>#define getchar ()</code>                                                                          |
| <b>Returns</b>     | The next character from the input stream. The return value <code>EOF</code> indicates an error occurred. |

**gets Macro**

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Siogets()</a> to read a string from the <code>stdin</code> input stream.                                                             |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                               |
| <b>Prototype</b>   | <code>#define gets (strP)</code>                                                                                                                       |
| <b>Parameters</b>  | $\leftarrow strP$<br>A pointer to the returned string.                                                                                                 |
| <b>Returns</b>     | A pointer to the string read from the input stream. If an error or <code>EOF</code> occurs before any characters are read, returns <code>NULL</code> . |
| <b>Comments</b>    | The returned string does not include a null terminator. You must ensure that the input line, if any, is sufficiently short to fit in the string.       |

**printf Macro**

|                    |                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Sioprintf()</a> to write formatted output to the <code>stdout</code> output stream.                                                                                                                                     |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                                                                                                                  |
| <b>Prototype</b>   | <code>#define printf (formatP, ...)</code>                                                                                                                                                                                                |
| <b>Parameters</b>  | $\rightarrow formatP$<br>A pointer to a format string that controls how subsequent arguments are converted for output.<br>$\rightarrow \dots$<br>Zero or more parameters to be formatted as specified by the <code>formatP</code> string. |

- Returns** Returns the number of characters written out (not including the null terminator used to end output strings).
- Comments** This function internally calls [StrVPrintf\(\)](#) to do the formatting. See that function for details on which format specifications are supported. Returns a negative number if there is an error.

### **putc Macro**

- Purpose** Calls [Siofputc\(\)](#) to write a character to the output stream.
- Declared In** StdIOPalm.h
- Prototype** `#define putc (c, fs)`
- Parameters**  $\rightarrow c$   
A character to write to the output stream.
- $\rightarrow fs$   
An output stream to which to write the character. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.
- Returns** The character that was written. If an error occurs, the value EOF is returned.

### **putchar Macro**

- Purpose** Calls [Siofputc\(\)](#) to write a character to the `stdout` output stream.
- Declared In** StdIOPalm.h
- Prototype** `#define putchar (c)`
- Parameters**  $\rightarrow c$   
A character to write to the `stdout` output stream.
- Returns** The character that was written. If an error occurs, the value EOF is returned.

### puts Macro

|                    |                                                                                |
|--------------------|--------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">Sioputs()</a> to write a string to the output stream stdout. |
| <b>Declared In</b> | StdIOPalm.h                                                                    |
| <b>Prototype</b>   | #define puts (strP)                                                            |
| <b>Parameters</b>  | → <i>strP</i><br>A pointer to the string to write to stdout.                   |
| <b>Returns</b>     | Returns a nonnegative value on success and the value EOF on error.             |

### SioAddCommand Function

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Adds a built-in command that is supplied by the standard IO provider application.                                                                                                                                                                       |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | void SioAddCommand (const Char *cmdStr,<br>SioMainProcPtr cmdProcP)                                                                                                                                                                                     |
| <b>Parameters</b>  | → <i>cmdStr</i><br>Pointer to a string that is the command name.<br><br>→ <i>cmdProcP</i><br>Pointer to the command entry point function (the <a href="#">SioMain()</a> function).                                                                      |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                        |
| <b>Comments</b>    | This routine is useful for registering a command that is inside the standard IO provider application instead of in its own database.<br><br>This routine must be used to test commands under the Simulator since it can't launch application databases. |

## Siofgetc Function

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the next character from the input stream.                                                                                                                                                        |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                             |
| <b>Prototype</b>   | Int16 Siofgetc (FILE *fs)                                                                                                                                                                               |
| <b>Parameters</b>  | <p>→ <i>fs</i></p> <p>An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented.</p> |
| <b>Returns</b>     | The next character from the input stream. The return value EOF indicates an error occurred.                                                                                                             |

## Siofgets Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a string from the input stream.                                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | Char *Siofgets (Char *strP, UInt16 maxChars, FILE *fs)                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>← <i>strP</i></p> <p>A pointer to the returned string.</p> <p>→ <i>maxChars</i></p> <p>The number of characters to read from the input stream, plus one for the null terminator.</p> <p>→ <i>fs</i></p> <p>An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented.</p> |
| <b>Returns</b>     | A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns NULL.                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | The returned string is always terminated by a null character.                                                                                                                                                                                                                                                                                                                                   |
| <b>See Also</b>    | <a href="#">fgets()</a>                                                                                                                                                                                                                                                                                                                                                                         |

## **Siofprintf Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write formatted output to an output stream.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <pre>Int16 Siofprintf (FILE *fs, const Char *formatP,<br/>...)</pre>                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p>→ <i>fs</i><br/>An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented.</p> <p>→ <i>formatP</i><br/>A pointer to a format string that controls how subsequent arguments are converted for output.</p> <p>→ ...<br/>Zero or more parameters to be formatted as specified by the <i>formatP</i> string.</p> |
| <b>Returns</b>     | Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.                                                                                                                                                                                                                                                                          |
| <b>Comments</b>    | This function internally calls <a href="#">StrVPrintf()</a> to do the formatting. See that function for details on which format specifications are supported.                                                                                                                                                                                                                                                                         |
| <b>See Also</b>    | <a href="#">fprintf()</a>                                                                                                                                                                                                                                                                                                                                                                                                             |

## **Sioputc Function**

|                    |                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write a character to the output stream.                                                                                                                                                                                                                           |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | <pre>Int16 Sioputc (Int16 c, FILE *fs)</pre>                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>c</i><br/>A character to write to the output stream.</p> <p>→ <i>fs</i><br/>An output stream to which to write the character. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented.</p> |

**Returns** The character that was written. If an error occurs, the value EOF is returned.

**See Also** [fputc\(\)](#)

## Siofputs Function

**Purpose** Write a string to the output stream.

**Declared In** StdIOPalm.h

**Prototype** `Int16 Siofputs (const Char *strP, FILE *fs)`

**Parameters**  $\rightarrow$  *strP*

A pointer to the string to write.

$\rightarrow$  *fs*

An output stream to which to write the string. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.

**Returns** Returns 0 on success and the value EOF on error.

**See Also** [fputs\(\)](#)

## Siogets Function

**Purpose** Read a string from the `stdin` input stream.

**Declared In** StdIOPalm.h

**Prototype** `Char *Siogets (Char *strP)`

**Parameters**  $\leftarrow$  *strP*

A pointer to the returned string.

**Returns** A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns NULL.

**Comments** The returned string does not include a null terminator. You must ensure that the input line, if any, is sufficiently short to fit in the string.

**See Also** [gets\(\)](#)

## Sioprintf Function

|                    |                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write formatted output to the stdout output stream.                                                                                                                                                                           |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                   |
| <b>Prototype</b>   | Int16 Sioprintf (const Char *formatP, ...)                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>formatP</i><br/>A pointer to a format string that controls how subsequent arguments are converted for output.</p> <p>→ ...<br/>Zero or more parameters to be formatted as specified by the <i>formatP</i> string.</p> |
| <b>Returns</b>     | Returns the number of characters written out (not including the null terminator used to end output strings).                                                                                                                  |
| <b>Comments</b>    | This function internally calls <a href="#">StrVPrintf()</a> to do the formatting. See that function for details on which format specifications are supported. Returns a negative number if there is an error.                 |
| <b>See Also</b>    | <a href="#">printf()</a>                                                                                                                                                                                                      |

## Sioputs Function

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Purpose</b>     | Write a string to the output stream stdout.                          |
| <b>Declared In</b> | StdIOPalm.h                                                          |
| <b>Prototype</b>   | Int16 Sioputs (const Char *strP)                                     |
| <b>Parameters</b>  | <p>→ <i>strP</i><br/>A pointer to the string to write to stdout.</p> |
| <b>Returns</b>     | Returns a nonnegative value on success and the value EOF on error.   |
| <b>See Also</b>    | <a href="#">puts()</a>                                               |

## Siosystem Function

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Execute another Stdio command.                                                                                                                                                                                                                           |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | Int16 Siosystem (const Char *cmdStrP)                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>cmdStrP</i></p> <p>A pointer to a string containing the command line to execute.</p>                                                                                                                                                             |
| <b>Returns</b>     | Returns a value $\geq 0$ on success or $< 0$ on failure.                                                                                                                                                                                                 |
| <b>Comments</b>    | This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with the name "Cmd- <i>cmdname</i> " where <i>cmdname</i> is the first word in the command string <i>cmdStrP</i> . |
| <b>See Also</b>    | <a href="#"><u>SioExecCommand()</u></a> , <a href="#"><u>system()</u></a>                                                                                                                                                                                |

## Siovfprintf Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write formatted output to the stdout output stream.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | Int16 Siovfprintf (FILE *fs, const Char *formatP, _Palm_va_list args)                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>fs</i></p> <p>An output stream to which to write the formatted output. ## Standard IO

### *sprintf*

---

- Comments** This function internally calls [StrVPrintf\(\)](#) to do the formatting. See that function for details on which format specifications are supported.
- See Also** [vfprintf\(\)](#)

### **sprintf Macro**

- Purpose** Calls [StrPrintf\(\)](#) to write formatted output to the stdout output stream.
- Declared In** StdIOPalm.h
- Prototype** `#define sprintf (formatP, ...)`
- Parameters**   
→ *formatP*  
A pointer to a format string that controls how subsequent arguments are converted for output.  
  
→ ...  
Zero or more parameters to be formatted as specified by the *formatP* string.
- Returns** Returns the number of characters written out (not including the null terminator used to end output strings).
- Comments** See [StrVPrintf\(\)](#) for details on which format specifications are supported. Returns a negative number if there is an error.

### **system Macro**

- Purpose** Calls [Siosystem\(\)](#) to execute another Stdio command.
- Declared In** StdIOPalm.h
- Prototype** `#define system (cmdStrP)`
- Parameters**   
→ *cmdStrP*  
A pointer to a string containing the command line to execute.
- Returns** Returns a value  $\geq 0$  on success or  $< 0$  on failure.
- Comments** This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with

the name "Cmd-*cmdname*" where *cmdname* is the first word in the command string *cmdStrP*.

**See Also**     [SioExecCommand\(\)](#)

## **vfprintf Macro**

**Purpose**        Calls [Siovfprintf\(\)](#) to write formatted output to the stdout output stream.

**Declared In**   *StdIOPalm.h*

**Prototype**    `#define vfprintf (fs, formatP, args)`

**Parameters**    $\rightarrow fs$

An output stream to which to write the formatted output. You can specify only the value *stdout* for this parameter; alternate streams are not currently implemented.

$\rightarrow formatP$

A pointer to a format string that controls how subsequent arguments are converted for output.

$\rightarrow args$

A pointer to a list of zero or more parameters to be formatted as specified by the *formatP* string.

**Returns**       Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.

**Comments**     This function internally calls [StrVPrintf\(\)](#) to do the formatting. See that function for details on which format specifications are supported.

### **vsprintf Macro**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Calls <a href="#">StrVPrintf()</a> to write formatted output to the stdout output stream.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <code>#define vsprintf (fs, formatP, args)</code>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <i>fs</i><br/>An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented.</p> <p>→ <i>formatP</i><br/>A pointer to a format string that controls how subsequent arguments are converted for output.</p> <p>→ <i>args</i><br/>A pointer to a list of zero or more parameters to be formatted as specified by the <i>y</i> string.</p> |
| <b>Returns</b>     | Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.                                                                                                                                                                                                                                                                                                   |
| <b>Comments</b>    | See <a href="#">StrVPrintf()</a> for details on which format specifications are supported.                                                                                                                                                                                                                                                                                                                                                                     |

## Standard IO Provider Functions

These functions are used by a standard IO provider application.

### **SioClearScreen Function**

|                    |                                             |
|--------------------|---------------------------------------------|
| <b>Purpose</b>     | Clears the entire standard IO output field. |
| <b>Declared In</b> | StdIOProvider.h                             |
| <b>Prototype</b>   | <code>void SioClearScreen (void)</code>     |
| <b>Parameters</b>  | None.                                       |
| <b>Returns</b>     | Returns nothing.                            |

## SioExecCommand Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Executes a command line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b> | StdIOProvider.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | Int16 SioExecCommand (const Char *cmd)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | → <i>cmd</i><br>A pointer to a string containing the command line to execute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Returns</b>     | Returns a value $\geq 0$ on success or $< 0$ on failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | <p>This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with the name "Cmd-<i>cmdname</i>" where <i>cmdname</i> is the first word in the command string <i>cmd</i>.</p> <p>If you pass the string "help" or "?" for the <i>cmd</i> parameter, SioExecCommand causes a help string to be printed for each built-in command. It actually executes each built-in command, passing the string "?" as <i>argv[1]</i>. Each command should handle this argument by printing a help line.</p> <p>The SioExecCommand function is faster than calling <a href="#">system()</a> to execute a command. However, SioExecCommand can be called only by the standard IO provider application, not the standard IO application.</p> |

## SioFree Function

|                    |                                      |
|--------------------|--------------------------------------|
| <b>Purpose</b>     | Closes down the standard IO manager. |
| <b>Declared In</b> | StdIOProvider.h                      |
| <b>Prototype</b>   | Err SioFree (void)                   |
| <b>Parameters</b>  | None.                                |
| <b>Returns</b>     | Returns 0 on success.                |

## **SioHandleEvent Function**

|                    |                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Handles an event in the form that contains the standard IO output field and scroll arrows if the event belongs to the text field or scroll arrows.                |
| <b>Declared In</b> | <code>StdIOProvider.h</code>                                                                                                                                      |
| <b>Prototype</b>   | <code>Boolean SioHandleEvent (SysEventType *event)</code>                                                                                                         |
| <b>Parameters</b>  | <code>→ event</code><br>Pointer to an <code>EventType</code> structure.                                                                                           |
| <b>Returns</b>     | Returns <code>true</code> if the event was handled and should not be processed by the application's own form event handler; returns <code>false</code> otherwise. |
| <b>Comments</b>    | This function must be called from the form event handler before it does its own processing with any of the objects unrelated to standard IO in the form.          |

## **SioInit Function**

|                    |                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Initializes the standard IO manager.                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>StdIOProvider.h</code>                                                                                                                                                                                                                                  |
| <b>Prototype</b>   | <code>Err SioInit (UInt16 formID, UInt16 fieldID, UInt16 scrollerID)</code>                                                                                                                                                                                   |
| <b>Parameters</b>  | <code>→ formID</code><br>The ID of the form that contains the input/output field.<br><code>→ fieldID</code><br>The ID of the field to be used for input/output.<br><code>→ scrollerID</code><br>The ID of the scroller associated with the input/output form. |
| <b>Returns</b>     | Returns 0 on success.                                                                                                                                                                                                                                         |

## **Application-Defined Function**

You must supply this function in your stdio application.

## **SioMain Function**

|                    |                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The main entry point for the stdio application.                                                                                                                                                   |
| <b>Declared In</b> | StdIOPalm.h                                                                                                                                                                                       |
| <b>Prototype</b>   | Int16 SioMain (UInt16 argc, const Char *argv[])                                                                                                                                                   |
| <b>Parameters</b>  | <div>→ <i>argc</i><br/>The number of parameters passed on the command line.</div> <div>→ <i>argv</i><br/>An array of character pointers, one for each parameter passed on the command line.</div> |
| <b>Returns</b>     | The return value from this routine is passed back to the system call that invoked it. Return 0 for no error.                                                                                      |

## Standard IO

*SioMain*

---

# String Manager

---

This chapter provides reference material for the string manager. The string manager API is declared in the header file `StringMgr.h`.

For more information, see [Chapter 8](#), “Text,” on page 255 of the *Palm OS Programmer’s Companion*, vol. I.

## String Manager Functions

### StrATol Function

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a string to an integer.                                      |
| <b>Declared In</b> | <code>StringMgr.h</code>                                             |
| <b>Prototype</b>   | <code>Int32 StrAToI (const Char *str)</code>                         |
| <b>Parameters</b>  | <code>→ str</code><br>Pointer to a string to convert.                |
| <b>Returns</b>     | Returns the integer.                                                 |
| <b>Comments</b>    | Use this function instead of the standard <code>atoi</code> routine. |

### StrCaselessCompare Function

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Compare two strings with case and accent insensitivity.                                |
| <b>Declared In</b> | <code>StringMgr.h</code>                                                               |
| <b>Prototype</b>   | <code>Int16 StrCaselessCompare (const Char *s1,<br/>const Char *s2)</code>             |
| <b>Parameters</b>  | <code>→ s1</code><br>Pointer to a string.<br><code>→ s2</code><br>Pointer to a string. |

## String Manager

### *StrCat*

---

**Returns** Returns 0 if the strings match.  
Returns a positive number if `s1 > s2`.  
Returns a negative number if `s1 < s2`.

**Comments** Use this function instead of the standard `strcmp` routine.  
To support systems that use multi-byte character encodings, consider using [`TxtCaselessCompare\(\)`](#) instead of this function (or [`TxtCompare\(\)`](#) for a case-sensitive comparison). Both functions can match single-byte characters with their multi-byte equivalents, but `TxtCaselessCompare` can also return the length of the matching text.

**See Also** [`StrNCaselessCompare\(\)`](#), [`TxtCaselessCompare\(\)`](#), [`StrCompare\(\)`](#), [`StrNCompare\(\)`](#)

## StrCat Function

**Purpose** Concatenate one null-terminated string to another.

**Declared In** `StringMgr.h`

**Prototype** `Char *StrCat (Char *dst, const Char *src)`

**Parameters**  $\rightarrow$  *dst*  
Pointer to the null-terminated destination string.  
 $\rightarrow$  *src*  
Pointer to the null-terminated source string.

**Returns** Returns a pointer to the destination string.

**Comments** Use this function instead of the standard `strcat` routine.

## StrChr Function

**Purpose** Look for a character within a string.

**Declared In** `StringMgr.h`

**Prototype** `Char *StrChr (const Char *str, WChar chr)`

**Parameters**  $\rightarrow$  *str*  
Pointer to the string to be searched.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | → <i>chr</i><br>Character to search for.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Returns</b>       | Returns a pointer to the first occurrence of character in <i>str</i> . Returns NULL if the character is not found.                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>      | Use this function instead of the standard <i>strchr</i> routine.<br><br>This function can handle both single-byte characters and multi-byte characters correctly. However, you should make sure that you pass a <i>WChar</i> variable to <i>StrChr</i> instead of a <i>Char</i> . If you pass a <i>Char</i> variable, the function sign-extends the variable to a <i>WChar</i> , which causes problems if the value is 0x80 or higher. |
| <b>Compatibility</b> | This routine does not correctly find a '\0' character on Palm OS® version 1.0.                                                                                                                                                                                                                                                                                                                                                         |
| <b>See Also</b>      | <a href="#">StrStr()</a>                                                                                                                                                                                                                                                                                                                                                                                                               |

## StrCompare Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Compare two strings.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Declared In</b> | <i>StringMgr.h</i>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>Int16 StrCompare (const Char *s1, const Char *s2)</code>                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | → <i>s1</i><br>Pointer to a string.<br><br>→ <i>s2</i><br>Pointer to a string.                                                                                                                                                                                                                                                                                                                                                            |
| <b>Returns</b>     | Returns 0 if the strings match.<br><br>Returns a positive number if <i>s1</i> sorts after <i>s2</i> alphabetically.<br><br>Returns a negative number if <i>s1</i> sorts before <i>s2</i> alphabetically.                                                                                                                                                                                                                                  |
| <b>Comments</b>    | Use this function or <a href="#">StrCompareAscii()</a> instead of the standard <i>strcmp</i> routine. This function is case sensitive.<br><br>To support systems that use multi-byte character encodings, consider using <a href="#">TxtCompare()</a> instead of this function. Both functions can match single-byte characters with their multi-byte equivalents, but <i>TxtCompare</i> can also return the length of the matching text. |

## String Manager

### *StrCompareAscii*

---

- Compatibility** Prior to Palm OS 4.0, `StrCompare` and [TxtCompare\(\)](#) only performed one level of comparison and returned as soon as they found two unequal characters. For example, if you compared the string “celery” with the string “Cauliflower,” both functions returned a value indicating that “celery” should appear before “Cauliflower” because they sorted “c” before “C.”
- In Palm OS 4.0, `StrCompare` calls `TxtCompare`, and `TxtCompare` performs a comparison using up to six comparison tables for sorting with increasing precision. As a result, in Palm OS 4.0 and higher, `StrCompare` sorts “Cauliflower” before “celery.”
- See Also** [StrNCompare\(\)](#), [StrNCaselessCompare\(\)](#), [TxtCaselessCompare\(\)](#)

## StrCompareAscii Function

- Purpose** Compare two ASCII strings.
- Declared In** `StringMgr.h`
- Prototype**

```
Int16 StrCompareAscii (const Char *s1,
                      const Char *s2)
```
- Parameters**
- *s1*  
Pointer to a string.
  - *s2*  
Pointer to a string.
- Returns**
- Returns 0 if the strings match.
  - Returns a positive number if *s1* sorts after *s2* alphabetically.
  - Returns a negative number if *s1* sorts before *s2* alphabetically.
- Comments** Use this function instead of the standard `strcmp` routine. Use it to do case-sensitive comparisons on strings that are guaranteed to be 7-bit ASCII strings. This function performs a fast, simple byte-to-byte comparison that is guaranteed never to change.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [StrCompare\(\)](#), [StrNCompare\(\)](#), [TxtCompare\(\)](#), [StrCaselessCompare\(\)](#), [StrNCaselessCompare\(\)](#), [TxtCaselessCompare\(\)](#), [StrNCompareAscii\(\)](#)

## StrCopy Function

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy one string to another.                                                                                                              |
| <b>Declared In</b> | StringMgr.h                                                                                                                              |
| <b>Prototype</b>   | Char *StrCopy (Char *dst, const Char *src)                                                                                               |
| <b>Parameters</b>  | <p>→ <i>dst</i><br/>Pointer to the destination string.</p> <p>→ <i>src</i><br/>Pointer to the source string.</p>                         |
| <b>Returns</b>     | Returns a pointer to the destination string.                                                                                             |
| <b>Comments</b>    | Use this function instead of the standard <code>strcpy</code> routine.<br>This function does not work properly with overlapping strings. |

## StrDelocalizeNumber Function

|                    |                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Delocalize a number passed in as a string. Convert the number from any localized notation to US notation (decimal point and thousandth comma). The current thousand and decimal separators have to be passed in.                     |
| <b>Declared In</b> | StringMgr.h                                                                                                                                                                                                                          |
| <b>Prototype</b>   | Char *StrDelocalizeNumber (Char *s,<br>Char thousandSeparator, Char decimalSeparator)                                                                                                                                                |
| <b>Parameters</b>  | <p>↔ <i>s</i><br/>Pointer to the number as an ASCII string.</p> <p>→ <i>thousandSeparator</i><br/>Current thousand separator.</p> <p>→ <i>decimalSeparator</i><br/>Current decimal separator.</p>                                    |
| <b>Returns</b>     | Returns a pointer to the changed number and modifies the string in <i>s</i> .                                                                                                                                                        |
| <b>Comments</b>    | The current <code>thousandSeparator</code> and <code>decimalSeparator</code> can be determined by obtaining the value of the <code>prefNumberFormat</code> preference using <a href="#">PrefGetPreference()</a> and then passing the |

## String Manager

### *StrIToA*

---

returned [NumberFormatType](#) to [LocGetNumberSeparators\(\)](#).  
For example:

---

```
Char *localizedNum;  
NumberFormatType numFormat;  
Char thousandsSeparator, decimalSeparator;  
  
numFormat = (NumberFormatType)  
    PrefGetPreference(prefNumberFormat);  
LocGetNumberSeparators(numFormat,  
    &thousandsSeparator, &decimalSeparator);  
StrDelocalizeNumber(localizedNum,  
    thousandsSeparator, decimalSeparator);
```

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [StrLocalizeNumber\(\)](#), [LocGetNumberSeparators\(\)](#)

## StrIToA Function

**Purpose** Convert an integer to ASCII.

**Declared In** StringMgr.h

**Prototype** Char \*StrIToA (Char \*s, Int32 i)

**Parameters**

- ← *s*  
Pointer to a string of size maxStrIToALen in which to store the results.
- *i*  
Integer to convert.

**Returns** Returns a pointer to the result string.

**See Also** [StrAToI\(\)](#), [StrIToH\(\)](#)

## StrToH Function

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert an integer to hexadecimal ASCII.                                                                                                                  |
| <b>Declared In</b> | StringMgr.h                                                                                                                                               |
| <b>Prototype</b>   | Char *StrToH (Char *s, UInt32 i)                                                                                                                          |
| <b>Parameters</b>  | <div><math>\leftarrow s</math><br/>Pointer to a string in which to store the results.</div> <div><math>\rightarrow i</math><br/>Integer to convert.</div> |
| <b>Returns</b>     | Returns the string pointer s.                                                                                                                             |
| <b>See Also</b>    | <a href="#">StrIToA()</a>                                                                                                                                 |

## StrLen Function

|                      |                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Compute the length of a string.                                                                                                                                                                                                                     |
| <b>Declared In</b>   | StringMgr.h                                                                                                                                                                                                                                         |
| <b>Prototype</b>     | UInt16 StrLen (const Char *src)                                                                                                                                                                                                                     |
| <b>Parameters</b>    | <div><math>\rightarrow src</math><br/>Pointer to a string.</div>                                                                                                                                                                                    |
| <b>Returns</b>       | Returns the length of the string in bytes.                                                                                                                                                                                                          |
| <b>Comments</b>      | <p>Use this function instead of the standard strlen routine.</p> <p>This function returns the length of the string in bytes. On systems that support multi-byte characters, the number returned does not always equal the number of characters.</p> |
| <b>Compatibility</b> | In Palm OS 3.5 and Palm OS 4.x this function was declared to return an Int16. In Palm OS 5, and prior to Palm OS 3.5, this function returns a UInt16.                                                                                               |

## StrLocalizeNumber Function

- Purpose** Convert a number (passed in as a string) to localized format, using a specified thousands separator and decimal separator.
- Declared In** StringMgr.h
- Prototype**

```
Char *StrLocalizeNumber (Char *s,  
                        Char thousandSeparator, Char decimalSeparator)
```

**Parameters**     $\leftrightarrow s$

Numeric ASCII string to localize.

$\rightarrow$  *thousandSeparator*

Localized thousand separator.

$\rightarrow$  *decimalSeparator*

Localized decimal separator.

**Returns**    Returns a pointer to the changed number. Converts the number string in *s* by replacing all occurrences of “,” with *thousandSeparator* and all occurrences of “.” with *decimalSeparator*.

**Comments**    The current *thousandSeparator* and *decimalSeparator* can be determined by obtaining the value of the *prefNumberFormat* preference using [PrefGetPreference\(\)](#) and then passing the returned [NumberFormatType](#) to [LocGetNumberSeparators\(\)](#). For example:

---

```
Char *localizedNum;  
NumberFormatType numFormat;  
Char thousandsSeparator, decimalSeparator;  
  
numFormat = (NumberFormatType)  
    PrefGetPreference(prefNumberFormat);  
LocGetNumberSeparators(numFormat,  
    &thousandsSeparator, &decimalSeparator);  
StrLocalizeNumber(localizedNum,  
    thousandsSeparator, decimalSeparator);
```

---

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present.

**See Also**    [StrDelocalizeNumber\(\)](#)

## StrNCaselessCompare Function

|                      |                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Compares two strings out to <i>n</i> characters with case and accent insensitivity.                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b>   | StringMgr.h                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | Int16 StrNCaselessCompare (const Char *s1,<br>const Char *s2, Int32 n)                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <p>→ <i>s1</i><br/>Pointer to the first string.</p> <p>→ <i>s2</i><br/>Pointer to the second string.</p> <p>→ <i>n</i><br/>Length in bytes of the text to compare.</p>                                                                                                                                                                                                 |
| <b>Returns</b>       | Returns 0 if the strings match.<br>Returns a positive number if <i>s1</i> > <i>s2</i> .<br>Returns a negative number if <i>s1</i> < <i>s2</i> .                                                                                                                                                                                                                        |
| <b>Comments</b>      | To support systems that use multi-byte character encodings, consider using <a href="#">TxtCaselessCompare()</a> instead of this function (or <a href="#">TxtCompare()</a> for a case-sensitive comparison). Both functions can match single-byte characters with their multi-byte equivalents, but TxtCaselessCompare can also return the length of the matching text. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present. As of Palm OS 4.0, both <i>s1</i> and <i>s2</i> must be null-terminated strings.                                                                                                                                                                                                                   |
| <b>See Also</b>      | <a href="#">StrNCompare()</a> , <a href="#">StrCaselessCompare()</a> ,<br><a href="#">TxtCaselessCompare()</a> , <a href="#">StrCompare()</a>                                                                                                                                                                                                                          |

## StrNCat Function

|                |                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Concatenates one string to another clipping the destination string to a maximum of <i>n</i> bytes (including the null character at the end). |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|

---

**IMPORTANT:** The Palm OS implementation of StrNCat differs from the implementation in the standard C library. See the Comments section for details.

| <b>Returns</b>       | Returns a pointer to the destination string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Comment</b>       | <p>This function differs from the standard C <code>strncat</code> function in these ways:</p> <ul style="list-style-type: none"><li>• <code>StrNCat</code> treats the parameter <i>n</i> as the maximum length in bytes for <i>dst</i>. That means it will copy at most <code>n - StrLen(dst) - 1</code> bytes from <i>src</i>. The standard C function always copies <i>n</i> bytes from <i>src</i> into <i>dst</i>. (It copies the entire <i>src</i> into <i>dst</i> if the length of <i>src</i> is less than <i>n</i>).</li><li>• If the length of the destination string reaches <i>n</i> - 1, <code>StrNCat</code> stops copying bytes from <i>src</i> and appends the terminating null character to <i>dst</i>. If the length of the destination string is already greater than or equal to <i>n</i> - 1 before the copying begins, <code>StrNCat</code> does not copy any data from <i>src</i>.</li><li>• In the standard C function, if <i>src</i> is less than <i>n</i>, the entire <i>src</i> string is copied into <i>dst</i> and then the remaining space is filled with null characters. <code>StrNCat</code> does not fill the remaining space with null characters in released ROMs. In debug ROMs, <code>StrNCat</code> fills the remaining bytes with the value 0xFE.</li></ul> <p>On systems with multi-byte character encodings, this function makes sure that it does not copy part of a multi-byte character. If the last byte copied from <i>src</i> contains the high-order or middle byte of a multi-byte character, <code>StrNCat</code> backs up in <i>dst</i> until the byte after the end of the previous character, and replaces that byte with a null character.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## StrNCompare Function

|                      |                                                                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Compare two strings out to <i>n</i> bytes. This function is case and accent sensitive.                                                                                                                                                                                               |
| <b>Declared In</b>   | StringMgr.h                                                                                                                                                                                                                                                                          |
| <b>Prototype</b>     | Int16 StrNCompare (const Char *s1, const Char *s2, Int32 n)                                                                                                                                                                                                                          |
| <b>Parameters</b>    | <div>→ <i>s1</i><br/>Pointer to a string.</div> <div>→ <i>s2</i><br/>Pointer to a string.</div> <div>→ <i>n</i><br/>Length in bytes of text to compare.</div>                                                                                                                        |
| <b>Returns</b>       | Returns 0 if the strings match.<br>Returns a positive number if <i>s1</i> > <i>s2</i> .<br>Returns a negative number if <i>s1</i> < <i>s2</i> .                                                                                                                                      |
| <b>Comments</b>      | To support systems that use multi-byte character encodings, consider using <a href="#">TxtCompare()</a> instead of this function. Both functions can match single-byte characters with their multi-byte equivalents, but TxtCompare can also return the length of the matching text. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present. As of Palm OS 4.0, both <i>s1</i> and <i>s2</i> must be null-terminated strings.                                                                                                                                 |
| <b>See Also</b>      | <a href="#">StrCompare()</a> , <a href="#">StrNCaselessCompare()</a> , <a href="#">StrCaselessCompare()</a> , <a href="#">TxtCaselessCompare()</a> , <a href="#">StrNCompareAscii()</a>                                                                                              |

## StrNCompareAscii Function

|                      |                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Compare two ASCII strings out to $n$ bytes.                                                                                                                                                                                                                                 |
| <b>Declared In</b>   | StringMgr.h                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | <pre>Int16 StrNCompareAscii (const Char *s1,<br/>                        const Char *s2, Int32 n)</pre>                                                                                                                                                                     |
| <b>Parameters</b>    | <p>→ <math>s1</math><br/>Pointer to a string.</p> <p>→ <math>s2</math><br/>Pointer to a string.</p> <p>→ <math>n</math><br/>Length in bytes of text to compare.</p>                                                                                                         |
| <b>Returns</b>       | <p>Returns 0 if the strings match.</p> <p>Returns a positive number if <math>s1</math> sorts after <math>s2</math> alphabetically.</p> <p>Returns a negative number if <math>s1</math> sorts before <math>s2</math> alphabetically.</p>                                     |
| <b>Comments</b>      | Use this function instead of the standard <code>strncmp</code> routine. Use it to do case-sensitive comparisons on strings that are guaranteed to be 7-bit ASCII strings. This function performs a fast, simple byte-to-byte comparison that is guaranteed never to change. |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                         |
| <b>See Also</b>      | <a href="#">StrCompare()</a> , <a href="#">StrNCompare()</a> , <a href="#">TxtCompare()</a> ,<br><a href="#">StrCaselessCompare()</a> , <a href="#">StrNCaselessCompare()</a> ,<br><a href="#">TxtCaselessCompare()</a> , <a href="#">StrCompareAscii()</a>                 |

## StrNCopy Function

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copies up to $n$ bytes from a source string to the destination string. Terminates <code>dst</code> string at index $n-1$ if the source string length was $n-1$ or less. |
| <b>Declared In</b> | StringMgr.h                                                                                                                                                             |
| <b>Prototype</b>   | <pre>Char *StrNCopy (Char *dst, const Char *src,<br/>               Int16 n)</pre>                                                                                      |
| <b>Parameters</b>  | <p>→ <math>dst</math><br/>Pointer to the destination string.</p>                                                                                                        |

## String Manager

### *StrNCopy*

---

→ *src*

Pointer to the source string.

→ *n*

Maximum number of bytes to copy from *src* string.

**Returns** Returns nothing.

**Comments** On systems with multi-byte character encodings, this function makes sure that it does not copy part of a multi-byte character. If the *n*th byte of *src* contains the high-order or middle byte of a multi-byte character, *StrNCopy* backs up in *dst* until the byte after the end of the previous character, and replaces the remaining bytes (up to *n*-1) with nulls.

Be aware that the *n*th byte of *dst* upon return may contain the last byte of a multi-byte character. If you plan to terminate the string by setting its last character to NULL, you must not pass the entire length of the string to *StrNCopy*. If you do, your code may overwrite the final byte of the last character.

---

```
// WRONG! You may overwrite part of multi-byte
// character.
Char dst[n];
StrNCopy(dst, src, n);
dst[n-1] = chrNull;
```

---

Instead, if you write to the last byte of the destination string, pass one less than the size of the string to *StrNCopy*.

---

```
// RIGHT. Instead pass n-1 to StrNCopy.
Char dst[n];
StrNCopy(dst, src, n-1);
dst[n-1] = chrNull;
```

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## StrPrintF Function

|                      |                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Implements a subset of the ANSI C <code>sprintf</code> call, which writes formatted output to a string.                                                                                                                                                     |
| <b>Declared In</b>   | <code>StringMgr.h</code>                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <code>Int16 StrPrintF (Char *s,<br/>                  const Char *formatStr, ...)</code>                                                                                                                                                                    |
| <b>Parameters</b>    | <p>→ <i>s</i><br/>    Pointer to a string into which the results are written.</p> <p>→ <i>formatStr</i><br/>    Pointer to the format specification string.</p> <p>...<br/>    Zero or more arguments to be formatted as specified by <i>formatStr</i>.</p> |
| <b>Returns</b>       | Number of characters written to destination string. Returns a negative number if there is an error.                                                                                                                                                         |
| <b>Comments</b>      | This function internally calls <a href="#">StrVPrintf()</a> to do the formatting. See that function's description—specifically, <a href="#">Table 47.1</a> on page 908—for details on which format specifications are supported.                            |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                         |
| <b>See Also</b>      | <a href="#">StrVPrintf()</a>                                                                                                                                                                                                                                |

## StrStr Function

|                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Look for a substring within a string.                                                                                                |
| <b>Declared In</b> | <code>StringMgr.h</code>                                                                                                             |
| <b>Prototype</b>   | <code>Char *StrStr (const Char *str, const Char *token)</code>                                                                       |
| <b>Parameters</b>  | <p>→ <i>str</i><br/>    Pointer to the string to be searched.</p> <p>→ <i>token</i><br/>    Pointer to the string to search for.</p> |
| <b>Returns</b>     | Returns a pointer to the first occurrence of <i>token</i> in <i>str</i> or NULL if not found.                                        |
| <b>Comments</b>    | Use this function instead of the standard <code>strstr</code> routine.                                                               |

## String Manager

### *StrToLower*

---

On systems with multi-byte character encodings, this function makes sure that it does not match only part of a multi-byte character. If the matching strings begins at an inter-character boundary, then this function returns `NULL`.

---

**NOTE:** If the value of the `token` parameter is the empty string, this function returns `NULL`. This is different than the standard `strstr` function, which returns `str` when `token` is the empty string.

---

## StrToLower Function

|                      |                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert all the characters in a string to lowercase.                                                                                                                                                                                |
| <b>Declared In</b>   | <code>StringMgr.h</code>                                                                                                                                                                                                            |
| <b>Prototype</b>     | <code>Char *StrToLower (Char *dst, const Char *src)</code>                                                                                                                                                                          |
| <b>Parameters</b>    | <div>→ <i>dst</i><br/>Pointer to a string.</div> <div>→ <i>src</i><br/>Pointer to a null-terminated string.</div>                                                                                                                   |
| <b>Returns</b>       | Returns a pointer to the destination string.                                                                                                                                                                                        |
| <b>Compatibility</b> | Prior to Palm OS version 3.5, this function only converted accented characters on Japanese devices. On Palm OS version 3.5 and higher, all characters are appropriately lowercased, including accented characters on Latin devices. |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Implements a subset of the ANSI C <code>vsprintf</code> call, which writes formatted output to a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | <code>StringMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <code>Int16 StrVPrintf (Char *s, const Char *formatStr, va_list arg)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><math>\leftarrow s</math><br/>Pointer to a string into which the results are written. This string is always terminated by a null terminator.</p> <p><math>\rightarrow formatStr</math><br/>Pointer to the format specification string.</p> <p><math>\rightarrow arg</math><br/>Pointer to a list of zero or more parameters to be formatted as specified by the <code>formatStr</code> string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Returns</b>     | Number of characters written to destination string, not including the null terminator. Returns a negative number if there is an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>    | <p>Like the C <code>vsprintf</code> function, this function is designed to be called by your own function that takes a variable number of arguments and passes them to this function. For details on how to use it, see <a href="#">“Using the StrVPrintf Function”</a> on page 271 of the <i>Palm OS Programmer’s Companion</i>, vol. I, or refer to <code>vsprintf</code> in a standard C reference book.</p> <p>Currently, only the conversion specifications <code>%d</code>, <code>%i</code>, <code>%u</code>, <code>%x</code>, <code>%s</code>, and <code>%c</code> are implemented by <code>StrVPrintf</code> (and related functions). Optional modifiers that are supported include: <code>+</code>, <code>-</code>, <code>&lt;space&gt;</code>, <code>*</code>, <code>&lt;digits&gt;</code>, <code>h</code> and <code>l</code> (long). Following is a brief description of how these format specifications work (see a C book for more details).</p> <p>Each conversion specification begins with the <code>%</code> character. Following the <code>%</code> character, there may be one or more of the characters list in <a href="#">Table 47.1</a>, in sequence.</p> |

**Table 47.1 StrVPrintf Format Specification**

| Character | Description                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| +         | <p>Specifies that a sign always be placed before a number produced by a signed conversion. A + overrides a space if both are used. Example:</p> <pre>StrPrintf(s, "%+d %+d", 4, -5);</pre> <p>Output to s:</p> <pre>+4 -5</pre>                                             |
| -         | <p>Specifies that the printed value is left justified within the field width allowed for it. Example:</p> <pre>StrPrintf(s, "%5d%-5d", 6, 9, 8);</pre> <p>Output to s:</p> <pre>69      8</pre>                                                                             |
| <space>   | <p>Specifies that a minus sign always be placed before a negative number and a space before a positive number. Example:</p> <pre>StrPrintf(s, "% d % d", 4, -5);</pre> <p>Output to s:</p> <pre>4 -5</pre>                                                                  |
| *         | <p>Indicates that the next argument (must be an integer) in the list specifies the field width. In this case, the argument following that one is used for the value of this field. Example:</p> <pre>StrPrintf(s, "%*d", 4, 8, 5);</pre> <p>Output to s:</p> <pre>8 5</pre> |

**Table 47.1 StrVPrintf Format Specification (*continued*)**

| Character    | Description                                                                                                                                                                                                                                                                                                                        |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <number>     | <p>Specifies a minimum field width. If the converted value has fewer characters than the field width, it will be padded with spaces on the left (or right, if the left justified flag is also specified) to fill out the field width. Example:</p> <pre>StrPrintf(s, "%d%5d", 4, 3);</pre> <p>Output to s:</p> <pre>4      3</pre> |
| h            | <p>Specifies that the following d, i, u, or x conversion corresponds to a short or unsigned short argument. Example:</p> <pre>StrPrintf(s, "%hd", 401);</pre> <p>Output to s:</p> <pre>401</pre>                                                                                                                                   |
| l or L       | <p>Specifies that the following d, i, u, x, or c conversion corresponds to a long or unsigned long</p> <pre>StrPrintf(s, "%ld", 999999999);</pre> <p>Output to s:</p> <pre>999999999</pre>                                                                                                                                         |
| <character>  | <p>A character that indicates the type of conversion to be performed. The supported conversion characters include:</p>                                                                                                                                                                                                             |
| d<br>or<br>i | <p>A signed integer argument is converted to decimal notation. Example:</p> <pre>StrPrintf(s, "%d    %d", 4, -4);</pre> <p>Output to s:</p> <pre>4      -4</pre>                                                                                                                                                                   |

**Table 47.1 StrVPrintf Format Specification (*continued*)**

| Character | Description                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u         | <p>An unsigned integer argument is converted to decimal notation. Example:</p> <pre>StrPrintf(s, "%u    %u", 4, -4);</pre> <p>Output to s:</p> <pre>4    65532</pre>                                                                             |
| x         | <p>An integer argument is converted to hexadecimal notation. Example:</p> <pre>StrPrintf(s, "%x", 125);</pre> <p>Output to s:</p> <pre>0000007D</pre>                                                                                            |
| s         | <p>A string (char *) argument is copied to the destination string. Example:</p> <pre>StrPrintf(s, "ABC%s", "DEF");</pre> <p>Output to s:</p> <pre>ABCDEF</pre>                                                                                   |
| c or C    | <p>A single character argument is copied to the destination string. If C is used or if the l modifier is used, the argument must be a WChar. Example:</p> <pre>StrPrintf(s, "Telephone%c", 's');</pre> <p>Output to s:</p> <pre>Telephones</pre> |
| %         | <p>A % character is copied to the destination string. Example:</p> <pre>StrPrintf(s, "%%");</pre> <p>Output to s:</p> <pre>%</pre>                                                                                                               |

**Example** Here's an example of how to use this call:

---

```
#include <unix_stdarg.h>
void MyPrintf(Char *s, Char *formatStr, ...)
{
    va_list args;
    Char text[0x100];
    va_start(args, formatStr);
    StrVPrintf(text, formatStr, args);
    va_end(args);
    MyPutS(text);
}
```

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **String Manager**

*StrVPrintf*

---

# System Event Manager

---

This chapter describes functions available in the system event manager. The system event manager API is declared in the header files `Event.h` and `SysEvtMgr.h`.

For more information on the system event manager, see the chapter “[Event Loop](#)” in the *Palm OS Programmer’s Companion*, vol. I. The reference for specific events sent by the system are documented in “[Palm OS Events](#).”

## System Event Manager Data Structures

The following system event manager data structures are documented in the “Palm OS Events” chapter:

- [eventsEnum](#)
- [EventType](#)
- [EventPtr](#)

## System Event Manager Functions

### EvtAddEventToQueue Function

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Purpose</b>     | Add an event to the event queue.                                    |
| <b>Declared In</b> | <code>Event.h</code>                                                |
| <b>Prototype</b>   | <code>void EvtAddEventToQueue (const EventType *event)</code>       |
| <b>Parameters</b>  | → <i>event</i><br>Pointer to the structure that contains the event. |
| <b>Returns</b>     | Returns nothing.                                                    |

## System Event Manager

### *EvtAddUniqueEventToQueue*

---

**Comments** This function makes a copy of the structure that you pass in and adds it to the event queue.

## EvtAddUniqueEventToQueue Function

**Purpose** Add an event to the event queue, replacing one of the same type if it is found.

**Declared In** `Event.h`

**Prototype**

```
void EvtAddUniqueEventToQueue
    (const EventType *eventP, UInt32 id,
     Boolean inplace)
```

**Parameters**

- *eventP*  
Pointer to the structure that contains the event.
- *id*  
ID of the event. 0 means match only on the type.
- *inPlace*  
If `true`, any existing event is replaced. If `false`, the existing event is deleted and a new event is added to end of queue.

**Returns** Returns nothing.

**Comments** This function looks for an event in the event queue of the same event type and ID (if specified). The routine replaces it with the new event, if found.

If no existing event is found, the new event is copied to the queue.

If an existing event is found, the routine proceeds as follows:

- If `inPlace` is `true`, the existing event is replaced with a copy of the new event.
- If `inPlace` is `false`, the existing event is removed and the new event is added to the end of the queue.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## EvtCopyEvent Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy an event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | Event.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>void EvtCopyEvent (const EventType *source,<br/>                  EventType *dest)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>source</i><br/>Pointer to the structure containing the event to copy.</p> <p>← <i>dest</i><br/>Pointer to the structure to copy the event to.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>Use this function only if you want to create an event that has the same type as the source event. The data field in an <a href="#">EventType</a> structure is specific to events of a given type. If you were to use this function to copy a <a href="#">keyDownEvent</a> and then change it to a <a href="#">frmLoadEvent</a>, the resulting frmLoadEvent would not have the proper data field.</p> <p>If you want to create an event of a different type, do not use EvtCopyEvent. First clear the EventType structure using <a href="#">MemSet ()</a> and then change the event type:</p> <hr/> <pre>MemSet (&amp;event, sizeof (EventType), 0);<br/>event.eType = frmLoadEvent;<br/>event.data.frmLoad.formID = formID;<br/>EvtAddEventToQueue (&amp;event);</pre> <hr/> |

## EvtDequeuePenPoint Function

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Get the next pen point out of the pen queue. This function is called by recognizers. |
| <b>Declared In</b> | SysEvtMgr.h                                                                          |
| <b>Prototype</b>   | <pre>Err EvtDequeuePenPoint (PointType *retP)</pre>                                  |
| <b>Parameters</b>  | ← <i>retP</i><br>Return point.                                                       |
| <b>Returns</b>     | Always returns 0.                                                                    |

## System Event Manager

### *EvtDequeuePenStrokeInfo*

---

**Comments**      Called by a recognizer that wishes to extract the points of a stroke. Returns the point (-1, -1) at the end of a stroke.

Before calling this routine, you must call [EvtDequeuePenStrokeInfo\(\)](#).

## EvtDequeuePenStrokeInfo Function

**Purpose**            Initiate the extraction of a stroke from the pen queue.

**Declared In**      `SysEvtMgr.h`

**Prototype**        `Err EvtDequeuePenStrokeInfo (PointType *startPtP, PointType *endPtP)`

**Parameters**       `← startPtP`  
                      Start point returned here.

`← endPtP`  
                      End point returned here.

**Returns**           Always returns 0.

**Comments**        Called by the system function `EvtGetSysEvent` when a [penUpEvent](#) is being generated. This routine must be called before [EvtDequeuePenPoint\(\)](#) is called.

Subsequent calls to `EvtDequeuePenPoint` return points at the starting point in the stroke and including the end point. After the end point is returned, the next call to [EvtDequeuePenPoint\(\)](#) returns the point -1, -1.

**See Also**         [EvtDequeuePenPoint\(\)](#)

## EvtEnableGraffiti Function

**Purpose**            Enable or disable Graffiti® or Graffiti 2 handwriting recognition.

**Declared In**      `SysEvtMgr.h`

**Prototype**        `void EvtEnableGraffiti (Boolean enable)`

**Parameters**       `→ enable`  
                      true to enable handwriting recognition, false to disable it.

**Returns**           Returns nothing.

## EvtEnqueueKey Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Place keys into the key queue.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <code>Err EvtEnqueueKey (WChar ascii, UInt16 keycode, UInt16 modifiers)</code>                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>ascii</i><br/>Character code for the key.</p> <p>→ <i>keycode</i><br/>Virtual key code of key. This is the <code>keyCode</code> field of the <a href="#">keyDownEvent</a> and is currently unused.</p> <p>→ <i>modifiers</i><br/>Modifiers for <code>keyDownEvent</code>.</p>                                                                                                                            |
| <b>Returns</b>     | Returns 0 if successful, or <code>evtErrParamErr</code> if an error occurs.                                                                                                                                                                                                                                                                                                                                      |
| <b>Comments</b>    | <p>This function disables interrupts while the queue header is being modified because both interrupt- and non-interrupt-level code can post keys into the queue.</p> <p>Entries in the key queue only take 1 byte if the <code>ascii</code> parameter has a value less than 256 and the <code>keycode</code> and <code>modifiers</code> parameters are both zero. Otherwise an entry can take up to 7 bytes.</p> |

---

**IMPORTANT:** Make sure you pass a `WChar` as the `ascii` parameter, not a `Char`. If you pass a high-ASCII `Char`, the compiler sign-extends it to be a 16-bit value, resulting in the wrong character being added to the key queue.

---

## EvtEventAvail Function

|                      |                                                                                   |
|----------------------|-----------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return <code>true</code> if an event is available.                                |
| <b>Declared In</b>   | <code>Event.h</code>                                                              |
| <b>Prototype</b>     | <code>Boolean EvtEventAvail (void)</code>                                         |
| <b>Parameters</b>    | <code>None</code> .                                                               |
| <b>Returns</b>       | Returns <code>true</code> if an event is available, <code>false</code> otherwise. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.               |

### **EvtFlushKeyQueue Function**

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Purpose</b>     | Flush all keys out of the key queue.                           |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                       |
| <b>Prototype</b>   | <code>Err EvtFlushKeyQueue (void)</code>                       |
| <b>Parameters</b>  | None.                                                          |
| <b>Returns</b>     | Always returns 0.                                              |
| <b>Comments</b>    | Called by the system function <code>EvtSetPenQueuePtr</code> . |

### **EvtFlushNextPenStroke Function**

|                    |                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Flush the next stroke out of the pen queue.                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | <code>Err EvtFlushNextPenStroke ()</code>                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | None.                                                                                                                                                                                                                                                                                |
| <b>Returns</b>     | Always returns 0.                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | Called by recognizers that need only the start and end points of a stroke. If a stroke has already been partially dequeued (by <a href="#">EvtDequeuePenStrokeInfo()</a> ) this routine finishes the stroke dequeuing. Otherwise, this routine flushes the next stroke in the queue. |
| <b>See Also</b>    | <a href="#">EvtDequeuePenPoint()</a>                                                                                                                                                                                                                                                 |

| <b>Parameters</b>  | <p><math>\leftarrow event</math><br/>Pointer to the structure to hold the event returned.</p> <p><math>\rightarrow timeout</math><br/>Maximum number of ticks to wait before an event is returned (<code>evtWaitForever</code> means wait indefinitely).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | <p>Pass <code>evtWaitForever</code> as the timeout in most instances. When running on the device, this makes the CPU go into doze mode until the user provides input. For applications that do animation, pass a timeout value greater than or equal to zero.</p> <p>Note that a timeout value greater than or equal to zero is simply the <i>maximum</i> number of ticks which can elapse before <code>EvtGetEvent</code> returns an event. If any other event—including a <code>nilEvent</code>—occurs before this time has elapsed, <code>EvtGetEvent</code> will return that event. Otherwise, once the specified time has elapsed <code>EvtGetEvent</code> generates and returns a <code>nilEvent</code>. If you supply a value of zero for the timeout parameter, <code>EvtGetEvent</code> returns the event currently in the queue, or, if there aren't any events in the queue, it immediately generates and returns a <code>nilEvent</code>.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## EvtGetPen Function

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the current status of the pen.                                                                                                                   |
| <b>Declared In</b> | <code>Event.h</code>                                                                                                                                    |
| <b>Prototype</b>   | <pre>void EvtGetPen (Int16 *pScreenX, Int16 *pScreenY,<br/>                Boolean *pPenDown)</pre>                                                     |
| <b>Parameters</b>  | <p><math>\leftarrow pScreenX</math><br/>x location relative to display.</p> <p><math>\leftarrow pScreenY</math><br/>y location relative to display.</p> |

## System Event Manager

### *EvtGetPenBtnList*

---

$\leftarrow pPenDown$   
true or false.

**Returns** Returns nothing.

**Comments** Called by various UI routines.

**See Also** [EvtGetPenNative\(\)](#), [KeyCurrentState\(\)](#)

## EvtGetPenBtnList Function

**Purpose** Return a pointer to the silk-screen button array.

**Declared In** `SysEvtMgr.h`

**Prototype** `const PenBtnInfoType *EvtGetPenBtnList  
(UInt16 *numButtons)`

**Parameters**  $\leftarrow numButtons$   
The number of elements in the returned array.

**Returns** Returns a pointer to an array of the silk-screen buttons.

**Comments** This function returns an array of `PenBtnInfoType` structures:

**Prototype**

```
typedef struct PenBtnInfoType {  
    RectangleType  boundsR;  
    WChar          asciiCode;  
    UInt16         keyCode;  
    UInt16         modifiers;  
} PenBtnInfoType;
```

The fields in the `PenBtnInfoType` contain the following information:

|                        |                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>boundsR</code>   | The button's bounding rectangle.                                                                                  |
| <code>asciiCode</code> | The character code generated when the button is tapped. This is typically a virtual character.                    |
| <code>keyCode</code>   | Currently unused.                                                                                                 |
| <code>modifiers</code> | Modifiers for the key down event. (See the description of the modifiers field for <a href="#">keyDownEvent</a> .) |

The number of buttons is device-dependent. Even devices with the same Palm OS® version may have differing numbers of silk-screen buttons. For example, Japanese devices typically have four extra silk-screen buttons used to transliterate characters into different alphabets.

**See Also**     [EvtProcessSoftKeyStroke\(\)](#)

## EvtGetPenNative Function

**Purpose**     Get the current status of the pen using a window's active coordinate system.

**Declared In**     `Window.h`

**Prototype**     `void EvtGetPenNative (WinHandle winH,  
                          Int16 *pScreenX, Int16 *pScreenY,  
                          Boolean *pPenDown)`

**Parameters**      $\rightarrow winH$   
                    Handle to a valid window.  
  
                     $\leftarrow pScreenX$   
                    x location relative to the window.  
  
                     $\leftarrow pScreenY$   
                    y location relative to the window.  
  
                     $\leftarrow pPenDown$   
                    true if the pen is down, false otherwise.

**Returns**     Returns nothing.

**Comments**     This function is a variation on [EvtGetPen\(\)](#). `EvtGetPen` returns a pen sample using the standard coordinate system, relative to the draw window, whereas `EvtGetPenNative` returns a pen sample using the active coordinate system of `winH`, relative to the window origin. If the active coordinate system is high density, the returned pen sample uses high-density coordinates.

On a debug ROM this function displays an error if `winH` doesn't reference a valid window object.

**Compatibility**     Implemented only if the [High-Density Display Feature Set](#) is present.

## EvtGetSilkscreenAreaList Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |        |                    |          |                                                                                                                                                                                                                                                         |       |                                                                                                                                                                                                                                      |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|--------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Returns a pointer to the silk-screen area array. This array contains the bounds of each silk-screen area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |        |                    |          |                                                                                                                                                                                                                                                         |       |                                                                                                                                                                                                                                      |
| <b>Declared In</b> | SysEvtMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |                    |          |                                                                                                                                                                                                                                                         |       |                                                                                                                                                                                                                                      |

| index              | If the area type is silkscreenRectGraffiti, this field is either alphaGraffitiSilkscreenArea to represent the portion where letters are entered or numericGraffitiSilkscreenArea to represent the portion where numbers are entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |        |                    |          |                                                                                                                                                                                                                                                         |       |                                                                                                                                                                                                                                      |

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. If [5.0 New Feature Set](#) is present, this function should be considered “System Use Only”; applications should do what they can to avoid using it.

## **EvtKeydownIsVirtual Macro**

**Purpose** Indicates if eventP is a pointer to a virtual character key down event.

**Declared In** `Event.h`

**Prototype** `#define EvtKeydownIsVirtual (eventP)`

**Parameters** `→ eventP`  
Pointer to an [EventType](#) structure.

**Returns** Returns `true` if the character is a letter in an alphabet or a numeric digit, `false` otherwise.

**Comments** The macro assumes that the caller has already determined the event is a `keyDownEvent`.

This macro is intended for use by the system. Applications should use [TxtGlueCharIsVirtual\(\)](#), contained in the [PalmOSGlue Library](#).

**Compatibility** Implemented in the Palm OS 3.5 SDK.

**See Also** [TxtGlueCharIsVirtual\(\)](#)

## **EvtKeyQueueEmpty Function**

**Purpose** Return `true` if the key queue is currently empty.

**Declared In** `SysEvtMgr.h`

**Prototype** `Boolean EvtKeyQueueEmpty (void)`

**Parameters** `None.`

**Returns** Returns `true` if the key queue is currently empty, otherwise returns `false`.

**Comments** Usually called by the key manager to determine if it should enqueue auto-repeat keys.

### **EvtKeyQueueSize Function**

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the size of the current key queue in bytes.                          |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                    |
| <b>Prototype</b>   | <code>UInt32 EvtKeyQueueSize (void)</code>                                  |
| <b>Parameters</b>  | None.                                                                       |
| <b>Returns</b>     | Returns size of queue in bytes.                                             |
| <b>Comments</b>    | Called by applications that wish to see how large the current key queue is. |

### **EvtPenQueueSize Function**

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Purpose</b>     | Return the size of the current pen queue in bytes.            |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                      |
| <b>Prototype</b>   | <code>UInt32 EvtPenQueueSize (void)</code>                    |
| <b>Parameters</b>  | None.                                                         |
| <b>Returns</b>     | Returns size of queue in bytes.                               |
| <b>Comments</b>    | Call this function to see how large the current pen queue is. |

### **EvtProcessSoftKeyStroke Function**

|                    |                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Translate a stroke in the system area of the digitizer and enqueue the appropriate key events in to the key queue. |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                                           |
| <b>Prototype</b>   | <code>Err EvtProcessSoftKeyStroke (PointType *startPtP,<br/>PointType *endPtP)</code>                              |
| <b>Parameters</b>  | <code>→ startPtP</code><br>Start point of stroke.<br><code>→ endPtP</code><br>End point of stroke.                 |
| <b>Returns</b>     | Returns 0 if recognized, -1 if not recognized.                                                                     |

## **EvtResetAutoOffTimer Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Reset the auto-off timer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <code>Err EvtResetAutoOffTimer (void)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Returns</b>     | Always returns 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>Called by the serial link manager; can be called periodically by other managers.</p> <p><code>EvtResetAutoOffTimer</code> resets the auto-off timer so that the device does not turn off until at least the default amount of idle time has passed. You can use this function to ensure that the device doesn't automatically power off during a long operation without user input (for example, when there is a lot of serial port activity).</p> <p>If you need more control over the auto-off timer and the <a href="#">3.5 New Feature Set</a> is present, consider using <a href="#"><code>EvtSetAutoOffTimer()</code></a> instead of this function.</p> |
| <b>See Also</b>    | <a href="#"><code>SysSetAutoOffTime()</code></a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## **EvtSetAutoOffTimer Function**

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the auto-off timer.                                                                                                                                                                                  |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Err EvtSetAutoOffTimer (EvtSetAutoOffCmd cmd, UInt16 timeout)</code>                                                                                                                               |
| <b>Parameters</b>  | <p>→ <i>cmd</i><br/>One of the defined commands.</p> <p>→ <i>timeout</i><br/>A new timeout value in seconds. If <i>cmd</i> is <code>ResetTimer</code>, this parameter is ignored.</p>                    |
| <b>Returns</b>     | Always returns <code>errNone</code> .                                                                                                                                                                    |
| <b>Comments</b>    | Use <code>EvtSetAutoOffTimer</code> to ensure that the device doesn't automatically power off during a long operation that has no user input (for example, when there is a lot of serial port activity). |

## System Event Manager

### *EvtSetNullEventTick*

---

The `cmd` parameter specifies the operation you want to perform. It takes one of the following `EvtSetAutoOffCmd` constants:

|                         |                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>SetAtLeast</code> | Make sure that the device won't turn off until <code>timeout</code> seconds of idle time has passed.<br><br>(This operation only changes the current value if it's less than the value you specify.) |
| <code>SetExactly</code> | Set the timer to turn off in <code>timeout</code> seconds                                                                                                                                            |
| <code>SetAtMost</code>  | Make sure the device will turn before <code>timeout</code> seconds has passed. (This operation only changes the current value if it's greater than the value you specify.)                           |
| <code>SetDefault</code> | Change the default auto-off timeout to <code>timeout</code> seconds.                                                                                                                                 |
| <code>ResetTimer</code> | Reset the auto-off timer so that the device does not turn off until at least the default seconds of idle time has passed.                                                                            |

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [EvtResetAutoOffTimer\(\)](#), [SysSetAutoOffTime\(\)](#)

## EvtSetNullEventTick Function

**Purpose** Make sure a [nilEvent](#) occurs in at least the specified number of ticks.

**Declared In** `SysEvtMgr.h`

**Prototype** `Boolean EvtSetNullEventTick(UInt32 tick)`

**Parameters**  $\rightarrow tick$

Maximum number of system ticks that should elapse before a `nilEvent` is added to the queue.

**Returns** Returns `true` if timeout value changed, or `false` if it did not change.

**Compatibility** In versions prior to Palm OS 3.5, this function was implemented as a macro.

## **EvtSysEventAvail Function**

|                      |                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return <code>true</code> if a low-level system event (such as a pen or key event) is available.                                                   |
| <b>Declared In</b>   | <code>SysEvtMgr.h</code>                                                                                                                          |
| <b>Prototype</b>     | <code>Boolean EvtSysEventAvail (Boolean ignorePenUps)</code>                                                                                      |
| <b>Parameters</b>    | <code>ignorePenUps</code><br>If <code>true</code> , this routine ignores pen-up events when determining if there are any system events available. |
| <b>Returns</b>       | Returns <code>true</code> if a system event is available.                                                                                         |
| <b>Comment</b>       | Call <a href="#">EvtEventAvail()</a> to determine whether high-level software events are available.                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                               |

## **EvtWakeup Function**

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Force the event manager to wake up and send a <a href="#">nilEvent</a> to the current application. |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                           |
| <b>Prototype</b>   | <code>Err EvtWakeup (void)</code>                                                                  |
| <b>Parameters</b>  | None.                                                                                              |
| <b>Returns</b>     | Always returns 0.                                                                                  |
| <b>Comments</b>    | Called by interrupt routines, like the sound manager and alarm manager.                            |
| <b>See Also</b>    | <a href="#">EvtWakeupWithoutNilEvent()</a>                                                         |

## **EvtWakeupWithoutNilEvent Function**

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Force the event manager to wake up without sending a <code>nilEvent</code> to the current application. |
| <b>Declared In</b> | <code>SysEvtMgr.h</code>                                                                               |
| <b>Prototype</b>   | <code>Err EvtWakeupWithoutNilEvent()</code>                                                            |
| <b>Parameters</b>  | None.                                                                                                  |

## System Event Manager

*EvtWakeupWithoutNilEvent*

---

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Returns</b>       | Always returns 0.                                                   |
| <b>Comments</b>      | Called by interrupt routines.                                       |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">EvtWakeup()</a>                                         |

# System Manager

---

This chapter provides reference material for the system manager. The system manager API is declared in the header files `SystemMgr.h` and `SysUtils.h`.

For more information on the system manager, see the chapters “[Application Startup and Stop](#)” and “[Palm System Support](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## System Manager Data Structures

### SysDBListItemType Struct

**Purpose** The `SysDBListItemType` structure describes a single database or panel. The [SysCreateDataBaseList\(\)](#) and [SysCreatePanelList\(\)](#) functions each create and return an array of `SysDBListItemType` structures.

**Prototype**

```
typedef struct {
    Char          name [dmDBNameLength] ;
    UInt32        creator;
    UInt32        type;
    UInt16        version;
    LocalID       dbID;
    UInt16        cardNo;
    BitmapPtr     iconP;
} SysDBListItemType;
```

## System Functions

### SysAppLaunch Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Launch a specified application as a subroutine of the caller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b> | <code>SystemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err SysAppLaunch (UInt16 cardNo, LocalID dbID,<br/>                  UInt16 launchFlags, UInt16 cmd, MemPtr cmdPBP,<br/>                  UInt32 *resultP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>cardNo</i>, <i>dbID</i><br/>The card number and ID of the resource database of the application to launch.</p> <p>→ <i>launchFlags</i><br/>Set to 0.</p> <p>→ <i>cmd</i><br/>Launch code.</p> <p>→ <i>cmdPBP</i><br/>Launch code parameter block.</p> <p>← <i>resultP</i><br/>The value returned from the application's <a href="#">PilotMain()</a> routine.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Returns</b>     | Returns 0 if no error, or one of <code>sysErrParamErr</code> , <code>memErrNotEnoughSpace</code> , or <code>sysErrOutOfOwnerIDs</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>Applications can use <code>SysAppLaunch</code> to send a specific launch code to another application and have control return to the calling application when finished. This function in effect makes the specified application a subroutine of the caller. If you want to actually close your application and call another application, use <a href="#">SysUIAppSwitch()</a> instead of this function. <code>SysUIAppSwitch</code> sends the current application an <code>appStopEvent</code> and then starts the specified application.</p> <p>Do not use this function to open the system-supplied Application Launcher application. If another application has replaced the default launcher with one of its own, this function will open the custom launcher instead of the system-supplied one. To open the</p> |

system-supplied launcher reliably, enqueue a `keyDownEvent` that contains a `launchChr`, as shown in the section “[Application Launcher](#)” of the user interface chapter in the *Palm OS Programmer’s Companion*, vol. I.

---

**NOTE:** For important information regarding the correct use of this function, see the “[Application Startup and Stop](#)” chapter in the *Palm OS Programmer’s Companion*, vol. I.

---

**See Also** [SysBroadcastActionCode\(\)](#), [SysUIAppSwitch\(\)](#), [SysCurAppDatabase\(\)](#)

## SysBatteryInfo Function

**Purpose** Retrieve settings for the batteries. Set `set` to `false` to retrieve battery settings. (Applications should **not** change any of the settings).

---

**WARNING!** Use this function only to **retrieve** settings!

---

**Declared In** `SystemMgr.h`

**Prototype**

```
UInt16 SysBatteryInfo (Boolean set,
    UInt16 *warnThresholdP,
    UInt16 *criticalThresholdP, Int16 *maxTicksP,
    SysBatteryKind *kindP, Boolean *pluggedIn,
    UInt8 *percentP)
```

**Parameters**

`set`  
 If `false`, parameters with non-NULL pointers are retrieved. Never set this parameter to `true`.

`warnThresholdP`  
 Pointer to battery voltage warning threshold in volts\*100, or NULL.

`criticalThresholdP`  
 Pointer to the battery voltage critical threshold in volts\*100, or NULL.

`maxTicksP`  
 Pointer to the battery timeout, or NULL.

## System Manager

### *SysBatteryInfoV20*

---

kindP

Pointer to the battery kind, or NULL.

pluggedIn

Pointer to pluggedIn return value, or NULL.

percentP

Percentage of power remaining in the battery.

#### Returns

Returns the current battery voltage in volts\*100.

#### Comments

Call this function to make sure an upcoming activity won't be interrupted by a low battery warning.

warnThresholdP and maxTicksP are the battery-warning voltage threshold and time out. If the battery voltage falls below the threshold, or the timeout expires, a lowBatteryChr key event is put on the queue. Normally, applications call [SysHandleEvent\(\)](#) which calls SysBatteryDialog in response to this event.

criticalThresholdP is the battery voltage threshold. If battery voltage falls below this level, the system turns itself off without warning and doesn't turn on until battery voltage is above it again.

#### Compatibility

This function was revised for Palm OS® 3.0. In Palm OS 3.0, the percentP parameter was added. This enhancement is implemented only if [3.0 New Feature Set](#) is present.

| <b>Prototype</b>     | <pre> UInt16 SysBatteryInfoV20 (Boolean set,     UInt16 *warnThresholdP,     UInt16 *criticalThresholdP, Int16 *maxTicksP,     SysBatteryKind *kindP, Boolean *pluggedIn) </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>    | <p><b>set</b><br/>         If false, parameters with non-NULL pointers are retrieved. Never set this parameter to true.</p> <p><b>warnThresholdP</b><br/>         Pointer to battery voltage warning threshold in volts*100, or NULL.</p> <p><b>criticalThresholdP</b><br/>         Pointer to the battery voltage critical threshold in volts*100, or NULL.</p> <p><b>maxTicksP</b><br/>         Pointer to the battery timeout, or NULL.</p> <p><b>kindP</b><br/>         Pointer to the battery kind, or NULL.</p> <p><b>pluggedIn</b><br/>         Pointer to pluggedIn return value, or NULL.</p>                                                               |
| <b>Returns</b>       | Returns the current battery voltage in volts*100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>      | <p>Call this function to make sure an upcoming activity won't be interrupted by a low battery warning.</p> <p>warnThresholdP and maxTicksP are the battery-warning voltage threshold and time out. If the battery voltage falls below the threshold, or the timeout expires, a lowBatteryChr key event is put on the queue. Normally, applications call <a href="#">SysHandleEvent()</a> which calls SysBatteryDialog in response to this event.</p> <p>criticalThresholdP is the battery voltage threshold. If battery voltage falls below this level, the system turns itself off without warning and doesn't turn on until battery voltage is above it again.</p> |
| <b>Compatibility</b> | This function corresponds to the Palm OS 2.0 version of SysBatteryInfo. Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Prototype</b>   | <pre>Boolean SysBinarySearch (void const *baseP,<br/>                          UInt16 numElements, Int16 width,<br/>                          SearchFuncPtr searchF, void const *searchData,<br/>                          Int32 other, Int32 *position,<br/>                          Boolean findFirst)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>baseP</b><br/>Base pointer to an array of elements</p> <p><b>numElements</b><br/>Number of elements to search. Must be greater than 0.</p> <p><b>width</b><br/>Width of each array element.</p> <p><b>searchF</b><br/>Search function.</p> <p><b>searchData</b><br/>Data to search for. This data is passed to the searchF function.</p> <p><b>other</b><br/>Data to be passed as the third parameter (the other parameter) to the comparison function.</p> <p><b>position</b><br/>Pointer to the position result.</p> <p><b>findFirst</b><br/>If set to true, the first matching element is returned. Use this parameter if the array contains duplicate entries to ensure that the first such entry will be the one returned.</p> |
| <b>Returns</b>     | <p>Returns true if an exact match was found. In this case, position points to the element number where the data was found.</p> <p>Returns false if an exact match was not found. If false is returned, position points to the element number where the data should be inserted if it was to be added to the array in sorted order.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | <p>The array must be sorted in ascending order prior to the search. Use <a href="#">SysInsertionSort()</a> or <a href="#">SysQSort()</a> to sort the array.</p> <p>The search starts at element 0 and ends at element (numOfElements - 1).</p> <p>The search function's (searchF) prototype is:</p> <pre>Int16 _searchF (void const *searchData,<br/>void const *arrayData, Int32 other);</pre> <p>The first parameter is the data for which to search, the second parameter is a pointer to an element in the array, and the third parameter is any other necessary data.</p> <p>The function returns:</p> <ul style="list-style-type: none"><li>• &gt; 0 if the search data is greater than the element</li><li>• &lt; 0 if the search data is less than the element</li><li>• 0 if the search data is the same as the element</li></ul> |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## SysBroadcastActionCode Function

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Send the specified action code (launch code) and parameter block to the latest version of every UI application.                                   |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                       |
| <b>Prototype</b>   | Err SysBroadcastActionCode (UInt16 cmd,<br>MemPtr cmdPBP)                                                                                         |
| <b>Parameters</b>  | <p>cmd<br/>Action code to send.</p> <p>cmdPBP<br/>Action code parameter block to send.</p>                                                        |
| <b>Returns</b>     | Returns 0 if no error, or one of the following errors: sysErrParamErr, memErrNotEnoughSpace, or sysErrOutOfOwnerIDs.                              |
| <b>See Also</b>    | <a href="#">SysAppLaunch()</a> , <a href="#">Chapter 2, "Application Startup and Stop."</a> of the <i>Palm OS Programmer's Companion</i> , vol. I |

## **SysCopyStringResource Function**

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy a resource string to a passed string.                                                                              |
| <b>Declared In</b> | SysUtils.h                                                                                                              |
| <b>Prototype</b>   | <pre>void SysCopyStringResource (Char *string,<br/>                             Int16 theID)</pre>                      |
| <b>Parameters</b>  | <p><code>string</code><br/>String to copy the resource string to.</p> <p><code>theID</code><br/>Resource string ID.</p> |
| <b>Returns</b>     | Stores a copy of the resource string in <code>string</code> .                                                           |

## **SysCreateDataBaseList Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Generate a list of databases found on the memory cards matching a specific type and return the result. If <code>lookupName</code> is <code>true</code> then a name in a <code>tAIN</code> resource is used instead of the database's name and the list is sorted. Only the last version of a database is returned. Databases with multiple versions are listed only once.                                                                                                        |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>Boolean SysCreateDataBaseList (UInt32 type,<br/>                               UInt32 creator, UInt16 *dbCount,<br/>                               MemHandle *dbIDs,<br/>                               Boolean lookupName)</pre>                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><code>type</code><br/>The type of database to find. Use 0 to find all databases.</p> <p><code>creator</code><br/>The creator ID of the database to find. Use 0 to find any creator ID.</p> <p><code>dbCount</code><br/>A pointer to an integer value that is updated by this function to the number of matching databases.</p> <p><code>dbIDs</code><br/>A pointer to a handle that gets allocated to contain the database list. Upon return, this references an array of</p> |

[SysDBListItemType](#) structures. See the Comments section below for more information.

lookupName

If true, SysCreateDatabaseList uses tAIN names and sorts the list.

**Returns** Returns false if no databases were found, and true if any databases were found. The value of dbCount is updated to reflect the number of databases that were found. If at least one database is found, dbIDs is updated to reference a array of [SysDBListItemType](#) structures; this array contains dbCount items.

**Comments** This function creates a list of unique databases, where unique is defined as having a different type and creator ID. Two or more databases with the same type and creator ID are counted as one. Thus, you cannot use SysCreateDataBaseList to build a list of databases that share a common type and creator. There are two exceptions to this rule, however. If type is 0 or if creator is not 0, the code that removes “non-unique” databases isn’t run. It also isn’t run if the type is sysFileTpqa, since web-clipping databases all have the same type and creator ID.

If this function returns true and the value of dbCount is greater than 0, than you can iterate through the list of database items, as shown in [Listing 49.1](#)

#### **Listing 49.1 Using the SysCreateDatabaseList function**

---

```

SysDBListItemType    *dbListIDsP;
MemHandle            dbListIDsH;
UInt16               dbCount = 0;
Boolean              status;
UInt16               counter;
SysDBListItemType    theItem;

status = SysCreateDatabaseList(sysFileTpqa, 0,
                               &dbCount, &dbListIDsH, false);

if (status == true && dbCount > 0)
{
    dbListIDsP = MemHandleLock (dbListIDsH);
    for (counter = 0; counter < dbCount; counter++)

```

## System Manager

### *SysCreatePanelList*

---

```
        if StrCompare(dbListIDsP[counter].name,
  "MINE") == 0
        // we found my database
        ...
    ...
    MemPtrFree (dbListIDsP);
}
```

---

**NOTE:** It is your responsibility to free the memory allocated by this function for the list of databases.

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysCreatePanelList Function

**Purpose** Generate a list of panels found on the memory cards and return the result. Multiple versions of a panel are listed once.

**Declared In** `SystemMgr.h`

**Prototype** `Boolean SysCreatePanelList (UInt16 *panelCount,  
MemHandle *panelIDs)`

**Parameters** `panelCount`

Pointer to set to the number of panels.

`panelIDs`

A pointer to a handle that gets allocated to contain the panel list. Upon return, this references an array of [SysDBListItemType](#) structures.

**Returns** Returns false if no panels were found, and true if any panels were found. The value of `panelCount` is updated to reflect the number of panels that were found. If at least one panel is found, `panelIDs` is updated to reference a array of [SysDBListItemType](#) structures; this array contains `panelCount` items.

**Comments** If this function returns true and the value of `panelCount` is greater than 0, than you can iterate through the list of panel items, as shown in [Listing 49.1](#). It is your responsibility to free the memory allocated for the panel list.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysCurAppDatabase Function

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the card number and database ID of the current application's resource database.                      |
| <b>Declared In</b> | SystemMgr.h                                                                                                 |
| <b>Prototype</b>   | <pre>Err SysCurAppDatabase (UInt16 *cardNoP,<br/>                        LocalID *dbIDP)</pre>              |
| <b>Parameters</b>  | <p>cardNoP<br/>    Pointer to the card number; 0 or 1.</p> <p>dbIDP<br/>    Pointer to the database ID.</p> |
| <b>Returns</b>     | Returns 0 if no error, or SysErrParamErr if an error occurs.                                                |
| <b>See Also</b>    | <a href="#">SysAppLaunch()</a> , <a href="#">SysUIAppSwitch()</a>                                           |

## SysErrString Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | <p>Returns text to describe an error number. This routine looks up the textual description of a system error number in the appropriate List resource and creates a string that can be used to display that error.</p> <p>The actual string will be of the form: "&lt;error message&gt; (XXXX)" where XXXX is the hexadecimal error number.</p> <p>This routine looks for a resource of type 'tstl' and resource ID of (err&gt;&gt;8). It then grabs the string at index (err &amp; 0x00FF) out of that resource.</p> <p>The first string in the resource is called index #1 by Constructor, NOT #0. For example, an error code of 0x0101 will fetch the first string in the resource.</p> |
| <b>Declared In</b> | SysUtils.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
|                      | <code>maxLen</code><br>Size of <code>strP</code> buffer.            |
| <b>Returns</b>       | Stores the error number string.                                     |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present. |

## SysFormPointerArrayToStrings Function

|                    |                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Form an array of pointers to strings in a block. Useful for setting the items of a list.                                                                                                                                              |
| <b>Declared In</b> | <code>SysUtils.h</code>                                                                                                                                                                                                               |
| <b>Prototype</b>   | <code>MemHandle SysFormPointerArrayToStrings (Char *c,<br/>Int16 stringCount)</code>                                                                                                                                                  |
| <b>Parameters</b>  | <code>c</code><br>Pointer to packed block of strings, each terminated by a null character.<br><code>stringCount</code><br>Count of strings in block.                                                                                  |
| <b>Returns</b>     | Unlocked handle to allocated array of pointers to the strings in the passed block. The returned array points to the strings in the passed packed block. Note that you'll need to free the returned handle when you no longer need it. |
| <b>See Also</b>    | <a href="#">LstSetListChoices()</a>                                                                                                                                                                                                   |

## sysFtrNumProcessorIs68K Macro

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Determines whether or not the underlying processor is part of the 68K family.                 |
| <b>Declared In</b> | <code>SystemMgr.h</code>                                                                      |
| <b>Prototype</b>   | <code>#define sysFtrNumProcessorIs68K(x)</code>                                               |
| <b>Parameters</b>  | <code>→ x</code><br>Processor type obtained from a call to <a href="#">FtrGet()</a> .         |
| <b>Returns</b>     | Returns <code>true</code> if the underlying processor is a 68K, <code>false</code> otherwise. |

**Comments** This macro is typically used in conjunction with [PceNativeCall\(\)](#).

---

**Example**

```
UInt32 processorType;

FtrGet(sysFileCSystem, sysFtrNumProcessorID, &processorType);
if (sysFtrNumProcessorIs68K(processorType)) {
    // processor is 68K
} else {
    // processor is not 68K
}
```

---

## **sysFtrNumProcessorIsARM Macro**

**Purpose** Determines whether or not the underlying processor is part of the ARM family.

**Declared In** SystemMgr.h

**Prototype** #define sysFtrNumProcessorIsARM(x)

**Parameters** → x  
Processor type obtained from a call to [FtrGet\(\)](#).

**Returns** Returns true if the underlying processor is an ARM core, false otherwise.

**Comments** This macro is typically used in conjunction with [PceNativeCall\(\)](#).

---

**Example**

```
UInt32 processorType;

FtrGet(sysFileCSystem, sysFtrNumProcessorID, &processorType);
if (sysFtrNumProcessorIsARM(processorType)) {
    // processor is ARM
} else {
    // processor is not ARM
}
```

---

## SysGetOSVersionString Function

|                      |                                                                                    |
|----------------------|------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the version number of the Palm™ operating system.                           |
| <b>Declared In</b>   | SystemMgr.h                                                                        |
| <b>Prototype</b>     | Char *SysGetOSVersionString()                                                      |
| <b>Parameters</b>    | None.                                                                              |
| <b>Returns</b>       | Returns a string such as “v. 3.0.”                                                 |
| <b>Comments</b>      | You must free the returned string using the <a href="#">MemPtrFree()</a> function. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                |

## SysGetROMToken Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return from ROM a value specified by token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | Err SysGetROMToken (UInt16 cardNo, UInt32 token,<br>UInt8 **dataP, UInt16 *sizeP)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <div>→ <i>cardNo</i><br/>The card on which the ROM to be queried resides. Currently, no Palm hardware provides multiple cards, so this value must be 0.</div> <div>→ <i>token</i><br/>The value to retrieve, as specified by one of the following tokens:<br/><br/>sysROMTokenSnum<br/>The serial number of the ROM, expressed as a text string with no null terminator.</div> <div>← <i>dataP</i><br/>Pointer to a text buffer that holds the requested value when the function returns.</div> <div>← <i>sizeP</i><br/>The number of bytes in the dataP buffer.</div> |
| <b>Returns</b>     | Returns the requested value if no error, or an error code if an error occurs. If this function returns an error, or if the returned pointer to                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                      |                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | the buffer is <code>NULL</code> , or if the first byte of the text buffer is <code>0xFF</code> , then no serial number is available.                                                                                   |
| <b>Comments</b>      | The serial number is shown to the user in the Application Launcher, along with a checksum digit you can use to validate input when your users read the ID from their device and type it in or tell it to someone else. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present. Serial numbers are available only on flash ROM-based units.                                                                                        |
| <b>See Also</b>      | <a href="#">“Retrieving the ROM Serial Number”</a> section in the <i>Palm OS Programmer’s Companion</i> , vol. I shows how to retrieve the ROM serial number and calculate its associated checksum.                    |

## SysGetStackInfo Function

|                      |                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the start and end of the current thread’s stack.                                                                                                                                                                                                    |
| <b>Declared In</b>   | <code>SystemMgr.h</code>                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>Boolean SysGetStackInfo (MemPtr *startPP,<br/>MemPtr *endPP)</code>                                                                                                                                                                                  |
| <b>Parameters</b>    | <code>startPP</code><br>Upon return, points to the start of the stack.<br><code>endPP</code><br>Upon return, points to the end of the stack.                                                                                                               |
| <b>Returns</b>       | Returns <code>true</code> if the stack has not overflowed, that is, the value of the stack overflow address has not been changed. Returns <code>false</code> if the stack overflow value has been overwritten, meaning that a stack overflow has occurred. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                        |

## SysGetTrapAddress Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the address of a function given its system trap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b>   | <code>SystemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | <code>void *SysGetTrapAddress (UInt16 trapNum)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | <p>→ <i>trapNum</i></p> <p>One of the routine selectors defined in <code>SysTraps.h</code> (<code>sysTrap...</code>) or <code>CoreTraps.h</code> on Palm OS version 3.5 and higher.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Returns</b>       | Returns the address of the corresponding function. Returns the address of the <code>sysTrapSysUnimplemented</code> routine if an invalid routine selector is passed; compare the results of this function to <code>SysGetTrapAddress(sysTrapSysUnimplemented)</code> if you need to check for an invalid routine selector.                                                                                                                                                                                                                                                                                                                                                               |
| <b>Comments</b>      | <p>Use this function for performance reasons. You can then use the address it returns to call the function without having to go through the trap dispatch table. This function is mostly useful for optimizing the performance of functions called in a tight loop.</p> <p>The Palm OS trap dispatch mechanism allows the trap table entries to be modified at any time, either as the result of a system update or a hack. For this reason, it's important to call this function <b>immediately before</b> entering the tight loop. If the trap address changes in between when you call <code>SysGetTrapAddress</code> and you use the address, the wrong function will be called.</p> |
| <b>Compatibility</b> | On Palm OS 3.0 and earlier, this function contains a bug that causes it to return a garbage value if an invalid routine selector is passed. To prevent this bug from affecting your application, use <code>SysGlueGetTrapAddress</code> in the <code>PalmOSGlue</code> library instead of calling this function directly. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                                                    |

## SysGremlins Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Query the Gremlins facility. You pass a selector for a function and parameters for that function. Gremlins performs the function call and returns the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b>   | <code>SysUtils.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>     | <code>UInt32 SysGremlins (GremlinFunctionType selector,<br/>GremlinParamsType *params)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>selector</code><br>The selector for a function to pass to Gremlins.<br><code>params</code><br>Pointer to a parameter block used to pass parameters to the function specified by <code>selector</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Returns</b>       | Returns the result of the function performed in Gremlins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>      | <p>Currently, only one selector is defined, <code>GremlinIsOn</code>, which takes no parameters. <code>GremlinIsOn</code> returns 0 if Gremlins is not running, non-zero if it is running.</p> <p>Currently, non-zero values are returned only from the version of Gremlins in the Palm OS emulator. The Gremlins running in the Simulator on a Macintosh and over the serial line via the Palm Debugger return zero for <code>GremlinIsOn</code>.</p> <p>Use this function if you need to alter the application's behavior when Gremlins is running. For example, the debug 3.0 ROM refuses to bring up the digitizer panel when Gremlins is running under the emulator.</p> |
| <b>Compatibility</b> | <p>Implemented only if <a href="#">3.0 New Feature Set</a> is present.</p> <p>In Palm OS 3.2 and later, <code>SysGremlins</code> is replaced by the functions defined in the file <code>HostControl.h</code>. Specifically, the one selector supported by <code>SysGremlins</code> is replaced with the function <code>HostGremlinIsRunning</code>. For backward compatibility, <code>SysGremlins</code> is mapped to <code>HostGremlinIsRunning</code>.</p>                                                                                                                                                                                                                  |

## SysHandleEvent Function

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Handle defaults for system events such as hard and soft key presses.                                                                                                                                                                                    |
| <b>Declared In</b> | <code>SystemMgr.h</code>                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <code>Boolean SysHandleEvent (EventPtr eventP)</code>                                                                                                                                                                                                   |
| <b>Parameters</b>  | <code>eventP</code><br>Pointer to an event.                                                                                                                                                                                                             |
| <b>Returns</b>     | Returns <code>true</code> if the system handled the event.                                                                                                                                                                                              |
| <b>Comments</b>    | Applications should call this routine immediately after calling <a href="#">EvtGetEvent()</a> unless they want to override the default system behavior. However, overriding the default system behavior is almost never appropriate for an application. |
| <b>See Also</b>    | <a href="#">EvtProcessSoftKeyStroke()</a> , <a href="#">KeyRates()</a>                                                                                                                                                                                  |

## SysInsertionSort Function

|                    |                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sort elements in an array according to the passed comparison function.                                                                                                                                                                                                                                                                |
| <b>Declared In</b> | <code>SysUtils.h</code>                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <code>void SysInsertionSort (void *baseP,<br/>                        UInt16 numElements, Int16 width,<br/>                        CmpFuncPtr comparF, Int32 other)</code>                                                                                                                                                            |
| <b>Parameters</b>  | <code>baseP</code><br>Base pointer to an array of elements.<br><code>numElements</code><br>Number of elements to sort (must be at least 2).<br><code>width</code><br>Width of an element.<br><code>comparF</code><br>Comparison function. See Comments, below.<br><code>other</code><br>Other data passed to the comparison function. |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                      |

**Comments** Only elements which are out of order move. Moved elements are moved to the end of the range of equal elements. If a large amount of elements are being sorted, try to use the quick sort (see [SysQSort\(\)](#)).

This is the insertion sort algorithm: Starting with the second element, each element is compared to the preceding element. Each element not greater than the last is inserted into sorted position within those already sorted. A binary search for the insertion point is performed. A moved element is inserted after any other equal elements.

In order to use `SysInsertionSort` you must write a comparison function with the following prototype:

```
Int16 comparF (void *p1, void *p2, Int32 other)
```

Your comparison function must return zero if `p1` equals `p2`, a positive integer value if `p1` is greater than `p2`, and a negative integer value if `p1` is less than `p2`. Note that the value of the parameter named `other` is passed through from the `SysInsertionSort` call and can be used to control the behavior of the `comparF` function if appropriate for your application.

**Compatibility** The Palm OS 2.0 comparison function (`comparF`) has this prototype:

```
Int comparF (VoidPtr, VoidPtr, Long other);
```

The Palm OS 1.0 comparison function (`comparF`) has this prototype:

```
Int comparF (BytePtr A, BytePtr B, Long other);
```

**See Also** [SysQSort\(\)](#)

## SysKeyboardDialog Function

|                      |                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Pop up the system keyboard if there is a field object with the focus. The field object's text chunk is edited directly. |
| <b>Declared In</b>   | Keyboard.h                                                                                                              |
| <b>Prototype</b>     | void SysKeyboardDialog (KeyboardType kbd)                                                                               |
| <b>Parameters</b>    | kbd<br>The keyboard type. See Keyboard.h.                                                                               |
| <b>Returns</b>       | Returns nothing. Changes the field's text chunk.                                                                        |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                     |
| <b>See Also</b>      | <a href="#">SysKeyboardDialogV10()</a> , <a href="#">FrmSetFocus()</a>                                                  |

## SysKeyboardDialogV10 Function

|                      |                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Pop up the system keyboard if there is a field object with the focus. The field object's text chunk is edited directly. |
| <b>Declared In</b>   | Keyboard.h                                                                                                              |
| <b>Prototype</b>     | void SysKeyboardDialogV10 ()                                                                                            |
| <b>Parameters</b>    | None.                                                                                                                   |
| <b>Returns</b>       | Returns nothing. The field's text chunk is changed.                                                                     |
| <b>Compatibility</b> | Corresponds to the 1.0 implementation of SysKeyboardDialog.                                                             |
| <b>See Also</b>      | <a href="#">SysKeyboardDialog()</a> , <a href="#">FrmSetFocus()</a>                                                     |

## SysLibFind Function

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a reference number for a library that is already loaded, given its name. |
| <b>Declared In</b> | SystemMgr.h                                                                     |
| <b>Prototype</b>   | Err SysLibFind (const Char *nameP,<br>UInt16 *refNumP)                          |
| <b>Parameters</b>  | nameP<br>Pointer to the name of a loaded library.                               |

`refNumP`

Pointer to a variable for returning the library reference number (on failure, this variable is undefined)

**Returns** 0 if no error; otherwise: `sysErrLibNotFound` (if the library is not yet loaded), or another error returned from the library's install entry point.

**Comments** Most built-in libraries (NetLib, serial, IR) are preloaded automatically when the system is reset. Third-party libraries must be loaded before this call can succeed (use [SysLibLoad\(\)](#)). You can check if a library is already loaded by calling `SysLibFind` and checking for a 0 error return value (it will return a non-zero value if the library is not loaded).

## SysLibInstall Function

**Purpose** Installs a library into the Library table and calls the library's install entry point.

**Declared In** `SystemMgr.h`

**Prototype** `Err SysLibInstall (SysLibEntryProcPtr libraryP,  
                  UInt16 *refNumP)`

**Parameters**  $\rightarrow$  *libraryP*

Pointer to the library being installed.

$\leftarrow$  *refNumP*

Pointer to the variable in which the installed library reference number is stored upon return.

**Returns** Returns 0 if no error, `memErrNotEnoughSpace` if an error occurs while allocating memory in the library table, or, if an error is returned by the call to the library's install entry point, that error is returned and the reference number is set to `sysInvalidRefNum`.

**Comments** This routine is largely used by the Palm OS, but can also be called by applications that need to install their own libraries.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysLibLoad Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Load a library given its database creator and type.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | SystemMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>     | Err SysLibLoad (UInt32 libType,<br>UInt32 libCreator, UInt16 *refNumP)                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | <div>libType<br/>    Type of library database.</div> <div>libCreator<br/>    Creator of library database.</div> <div>refNumP<br/>    Pointer to variable for returning the library reference number<br/>    (on failure, sysInvalidRefNum is returned in this variable)</div>                                                                                                                                                                                                                             |
| <b>Returns</b>       | 0 if no error; otherwise: sysErrLibNotFound, sysErrNoFreeRAM, sysErrNoFreeLibSlots, or other error returned from the library's install entry point.                                                                                                                                                                                                                                                                                                                                                       |
| <b>Comments</b>      | <p>Presently, the “load” functionality is <b>not</b> supported when you use the Palm OS Simulator.</p> <p>When an application no longer needs a library that it <b>successfully</b> loaded via SysLibLoad, it is responsible for unloading the library by calling <a href="#">SysLibRemove()</a> and passing it the library reference number returned by SysLibLoad. More information is available in the white paper on shared libraries, which you can find on the Palm developer support web site.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## SysLibRemove Function

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Unload a library previously loaded with <a href="#">SysLibLoad()</a> .                         |
| <b>Declared In</b> | SystemMgr.h                                                                                    |
| <b>Prototype</b>   | Err SysLibRemove (UInt16 refNum)                                                               |
| <b>Parameters</b>  | <div>→ refNum<br/>    The library reference number.</div>                                      |
| <b>Returns</b>     | 0 if no error; otherwise sysErrParamErr if the refNum is not a valid library reference number. |

**Comments** SysLibRemove releases the dynamic memory allocated to the shared library's dispatch table, resources, and global variables.

## SysQSort Function

**Purpose** Sort elements in an array according to the supplied comparison function.

**Declared In** SysUtils.h

**Prototype** void SysQSort (void \*baseP, UInt16 numElements, Int16 width, CmpFuncPtr comparF, Int32 other)

**Parameters**

baseP  
Base pointer to an array of elements.

numElements  
Number of elements to sort (must be at least 2).

width  
Width of an element.

comparF  
Comparison function. See Comments, below.

other  
Other data passed to the comparison function.

**Returns** Returns nothing.

**Comments** Equal records can be in any position relative to each other because a quick sort tends to scramble the ordering of records. As a result, calling SysQSort multiple times can result in a different order if the records are not completely unique. If you don't want this behavior, use the insertion sort instead (see [SysInsertionSort\(\)](#)).

To pick the pivot point, the quick sort algorithm picks the middle of three records picked from around the middle of all records. That way, the algorithm can take advantage of partially sorted data.

These optimizations are built in:

- The routine contains its own stack to limit uncontrolled recursion. When the stack is full, an insertion sort is used because it doesn't require more stack space.

- An insertion sort is also used when the number of records is low. This avoids the overhead of a quick sort which is noticeable for small numbers of records.
- If the records seem mostly sorted, an insertion sort is performed to move only those few records that need to be moved.

In order to use `SysQSort` you must write a comparison function with the following prototype:

```
Int16 comparF (void *p1, void *p2, Int32 other)
```

Your comparison function must return zero if `p1` equals `p2`, a positive integer value if `p1` is greater than `p2`, and a negative integer value if `p1` is less than `p2`. Note that the value of the parameter named `other` is passed through from the `SysQSort` call and can be used to control the behavior of the `comparF` function if appropriate for your application.

**Compatibility** The Palm OS 2.0 comparison function (`comparF`) has this prototype:

```
Int comparF (VoidPtr, VoidPtr, Long other);
```

The Palm OS 1.0 comparison function (`comparF`) has this prototype:

```
Int comparF (BytePtr A, BytePtr B, Long other);
```

**See Also** [SysInsertionSort\(\)](#)

## SysRandom Function

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Purpose</b>     | Return a random number anywhere from 0 to <code>sysRandomMax</code> . |
| <b>Declared In</b> | <code>SysUtils.h</code>                                               |
| <b>Prototype</b>   | <code>Int16 SysRandom (Int32 newSeed)</code>                          |
| <b>Parameters</b>  | <code>newSeed</code><br>New seed value, or 0 to use existing seed.    |
| <b>Returns</b>     | Returns a random number.                                              |

## **SysReset Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Perform a soft reset and reinitialize the globals and the dynamic memory heap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | void SysReset (void)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Returns</b>     | No return value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | <p>This routine resets the system, reinitializes the globals area and all system managers, and reinitializes the dynamic heap. All database information is preserved. This routine is called when the user presses the hidden reset switch on the device.</p> <p>When running an application using the simulator, this routine looks for two data files that represent the memory of card 0 and card 1. If these are found, the Palm OS memory image is created using them. If they are not found, they are created.</p> <p>When running an application on the device, this routine simply looks for the memory cards at fixed locations.</p> |

## **SysSetAutoOffTime Function**

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the time out value in seconds for auto-power-off. Zero means never power off. |
| <b>Declared In</b> | SystemMgr.h                                                                       |
| <b>Prototype</b>   | UInt16 SysSetAutoOffTime (UInt16 seconds)                                         |
| <b>Parameters</b>  | seconds<br>Time out in seconds, or 0 for no time out.                             |
| <b>Returns</b>     | Returns previous value of time out in seconds.                                    |

## SysSetTrapAddress Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the address of the function corresponding to a system trap.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>SystemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Err SysSetTrapAddress (UInt16 trapNum,<br/>void *procP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p>→ <i>trapNum</i><br/>One of the routine selectors defined in <code>SysTraps.h</code> (<code>sysTrap...</code>) or <code>CoreTraps.h</code> on Palm OS version 3.5 and higher.</p> <p>→ <i>procP</i><br/>Pointer to a function that the trap identified by <code>trapNum</code> is to point to.</p>                                                                                                                                                                                                    |
| <b>Returns</b>     | Returns 0 if no error, or <code>SysErrParamErr</code> if <code>trapNum</code> is greater than the number of traps in the trap table.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | This function is useful for patching a system trap, in combination with <a href="#">SysGetTrapAddress()</a> . To patch a system trap in your application, first call <code>SysGetTrapAddress</code> to get the trap address and then save this value somewhere. Next use <code>SysSetTrapAddress</code> to set the trap address to point to your function. Before your application exits, remove the patch by calling <code>SysSetTrapAddress</code> and passing in the original trap address you saved. |

---

**WARNING!** If your application patches a system trap using this function, you **must** remove the patch before your application exits. Do **not** use this mechanism to permanently patch system traps as it may cause unpredictable results for the system and other applications.

---

**Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

## SysStringByIndex Function

|                      |                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Copy a string out of a string list resource by index. String list resources are of type 'tSTL' and contain a list of strings and a prefix string.<br><br>ResEdit always displays the items in the list as starting at 1, not 0. Consider this when creating your string list. |
| <b>Declared In</b>   | SysUtils.h                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | Char *SysStringByIndex (UInt16 resID,<br>UInt16 index, Char *strP, UInt16 maxLen)                                                                                                                                                                                             |
| <b>Parameters</b>    | resID<br>Resource ID of the string list.<br><br>index<br>String to get out of the list.<br><br>strP<br>Pointer to space to form the string.<br><br>maxLen<br>Size of strP buffer.                                                                                             |
| <b>Returns</b>       | Returns a pointer to the copied string. The string returned from this call will be the prefix string appended with the designated index string. Indices are 0-based; index 0 is the first string in the resource.                                                             |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                                           |

## SysTaskDelay Function

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Purpose</b>     | Put the processor into doze mode for the specified number of ticks.         |
| <b>Declared In</b> | SystemMgr.h                                                                 |
| <b>Prototype</b>   | Err SysTaskDelay (Int32 delay)                                              |
| <b>Parameters</b>  | delay<br>Number of ticks to wait (see <a href="#">SysTicksPerSecond()</a> ) |
| <b>Returns</b>     | Returns 0 if no error.                                                      |
| <b>See Also</b>    | <a href="#">EvtGetEvent()</a>                                               |

## SysTicksPerSecond Function

|                      |                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the number of ticks per second. This routine allows applications to be tolerant of changes to the ticks per second rate in the system. |
| <b>Declared In</b>   | SystemMgr.h                                                                                                                                   |
| <b>Prototype</b>     | UInt16 SysTicksPerSecond (void)                                                                                                               |
| <b>Parameters</b>    | None                                                                                                                                          |
| <b>Returns</b>       | Returns the number of ticks per second.                                                                                                       |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                           |

## SysUIAppSwitch Function

|                    |                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Try to make the current UI application quit and then launch the UI application specified by card number and database ID.                                                                                                                                                                                                                     |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>   | Err SysUIAppSwitch (UInt16 cardNo, LocalID dbID, UInt16 cmd, MemPtr cmdPBP)                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <ul style="list-style-type: none"><li>→ <i>cardNo</i><br/>Card number for the new application; currently only card 0 is valid.</li><li>→ <i>dbID</i><br/>ID of the new application's resource database.</li><li>→ <i>cmd</i><br/>Action code (launch code).</li><li>→ <i>cmdPBP</i><br/>Action code (launch code) parameter block.</li></ul> |
| <b>Returns</b>     | Returns 0 if no error.<br><br>May display a fatal error message if the <i>cardNo</i> parameter is invalid. On debug ROMs, displays a fatal error message if there is no currently running application.                                                                                                                                       |
| <b>Comments</b>    | Do not use this function to open the system-supplied Application Launcher application. If a third-party launch is installed, you'll likely want to launch that one instead. To do this, enqueue a                                                                                                                                            |

keyDownEvent that contains a launchChr, as shown in the section “[Application Launcher](#)” of the user interface chapter in the *Palm OS Programmer’s Companion*, vol. I. This will run whatever is run whenever you tap on the Applications icon.

If you are passing a parameter block (the cmdPBP parameter), you must set the owner of the parameter block chunk to the operating system. To do this, and for more information, see [MemPtrSetOwner\(\)](#). If the parameter block structure contains references by pointer or handle to any other chunks, you also must set the owner of those chunks by using [MemHandleSetOwner\(\)](#) or MemPtrSetOwner. If you set the owner of this parameter block properly, the system maintains the parameter block and frees it when the second application quits. If you don’t set the owner of the parameter block, the system frees the parameter block as soon as the calling application quits, causing unpredictable results.

**See Also** [SysAppLaunch\(\)](#), [Chapter 2](#), “[Application Startup and Stop](#),” in the *Palm OS Programmer’s Companion*, vol. I.

## Application-Defined Functions

### PilotMain Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The entry point for all Palm OS applications, this function’s sole purpose is to receive and respond to launch codes.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | SystemMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>UInt32 PilotMain(UInt16 cmd, void *cmdPBP,                  UInt16 launchFlags)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>cmd</i></p> <p>The launch code to which your application is to respond. See <a href="#">Chapter 1</a>, “<a href="#">Application Launch Codes</a>,” on page 3 for a list of predefined launch codes. You may create additional launch codes; see “<a href="#">Creating Your Own Launch Codes</a>” on page 28 of the <i>Palm OS Programmer’s Companion</i>, vol. I.</p> <p>→ <i>cmdPBP</i></p> <p>A pointer to a structure containing any launch-command-specific parameters, or NULL if the launch code has none. See</p> |

the description of each launch code for a description of the parameter structure that accompanies it, if any.

→ *launchFlags*

Flags that indicate whether your application's global variables are available, whether your application is now the active application, whether it already was the active application, and so on. See "[Launch Flags](#)" on page 37 for a list of launch flags.

**Returns** Return `errNone` if your application processed the launch code successfully, or an appropriate error code if there was a problem. When another application invokes your application using [`SysAppLaunch\(\)`](#), this value is returned to the caller.

**Comments** See [Chapter 2, "Application Startup and Stop,"](#) on page 19 of the *Palm OS Programmer's Companion*, vol. I for a discussion on how applications receive and handle launch codes, with examples.

# Text Manager

---

This chapter provides information about the text manager API declared in `TextMgr.h` by discussing these topics:

- [Text Manager Data Structures](#)
- [Text Manager Constants](#)
- [Text Manager Functions](#)

For more information on the text manager, see the chapter “[Localized Applications](#)” on page 369 in the *Palm OS Programmer’s Companion*, vol. I.

## Text Manager Data Structures

### CharEncodingType Typedef

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>   | The <code>CharEncodingType</code> enum specifies possible character encodings. The <a href="#">Character Encoding Constants</a> define the possible values for <code>CharEncodingType</code> variables.                                                                                                                                                                                                                                                                       |
| <b>Prototype</b> | <code>UInt8 CharEncodingType;</code>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>  | A given handheld supports a single character encoding. The currently available handhelds support either the Palm™ version of Windows code page 1252 <sup>1</sup> (an extension of ISO Latin 1), the Palm version of Windows code page 932 <sup>1</sup> (an extension of Shift JIS), or GB2312. In addition, Palm OS licensees and some third-party developers provide support for additional character encodings including Big-5, Hebrew, Arabic, Thai, Korean, and Cyrillic. |

---

1. This encoding is identical to its Windows counterpart with some additional characters added in the control range.

**Compatibility** Prior to version 4.0, CharEncodingType was an enum that defined only eight character encodings. The Palm OS® 4.0 definition of CharEncodingType is compatible with the previous definition.

## TranslitOpType Typedef

**Purpose** Specifies the transliteration operation to be performed by a given call to [TxtTransliterate\(\)](#). Each character encoding contains its own set of special transliteration operations, the values for which begin at translitOpCustomBase.

**Prototype** `typedef UInt16 TranslitOpType;`

**Comments** The following operations are always available, regardless of the character encoding used on the handheld:

| Constant             | Value  | Description                                                                                                                                                                                                                 |
|----------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| translitOpUpperCase  | 0      | Converts the character to uppercase letters.                                                                                                                                                                                |
| translitOpLowerCase  | 1      | Converts the characters to lowercase letters.                                                                                                                                                                               |
| translitOpReserved2  | 2      | Reserved                                                                                                                                                                                                                    |
| translitOpReserved3  | 3      | Reserved                                                                                                                                                                                                                    |
| translitOpPreprocess | 0x8000 | A mask that , when OR'd to a transliteration operation value, indicates that TxtTransliterate should not perform the operation but should instead return (in ioDstLength) the amount of space required for the output text. |

## TxtConvertStateType Struct

**Purpose** This structure is used to maintain state across calls to [TxtConvertEncoding\(\)](#). It is essentially opaque; simply declare a structure of this type and pass a pointer to your structure when making multiple calls to TxtConvertEncoding for a single source text buffer.

**Prototype** `typedef struct {`

```
UInt8 ioSrcState[kTxtConvertStateSize];  
UInt8 ioDstState[kTxtConvertStateSize];  
} TxtConvertStateType;
```

kTxtConvertStateSize is simply a constant that determines the size of the source and destination state buffers.

## Text Manager Constants

### Character Encoding Constant Modifiers

The following flag can be OR'd with the destination character encoding constant (one of those listed in "[Character Encoding Constants](#)" on page 737) that is passed to [TxtConvertEncoding\(\)](#).

| Constant                   | Value | Description                                                                                                                                                      |
|----------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| charEncodingDstBestFitFlag | 0x80  | Causes TxtConvertEncoding to make an extra effort to convert characters in the source encoding to similar (if not equal) characters in the destination encoding. |

As an example, when converting from charEncodingUCS2 to charEncodingPalmGB, no mapping exists for 0x00A1 (INVERTED EXCLAMATION MARK), since this character doesn't exist within charEncodingPalmGB. In this instance, then TxtConvertEncoding returns txtErrNoCharMapping for this mapping. If you OR the charEncodingDstBestFitFlag with the destination character encoding, however, TxtConvertEncoding converts the character to chrExclamationMark (which is close). Generally, the operating system tries to support as many CP1252 characters as possible in the "best fit" table.

If charEncodingDstBestFitFlag is 1 and either the source or destination encoding is unknown, TxtConvertEncoding copies anything that is 7-bit ASCII from the source to the destination. It then returns txtErrUnknownEncodingFallbackCopy. The rules

## Text Manager

### Character Encoding Feature Attributes

---

for unknown characters apply during this 7-bit copy; if an unconvertible character is encountered the substitution string (if one has been specified) is used in its place and `txtErrNoCharMapping` is returned instead.

#### Compatibility

The `charEncodingDstBestFitFlag` is only supported in Palm OS versions that don't support Simplified Chinese. On Palm OS versions that don't support Simplified Chinese, use of this flag will prevent `TxtConvertEncoding` from recognizing the destination encoding. To safely use the best fit flag on a variety of Palm OS releases, call `TxtGlueConvertEncoding` instead of `TxtConvertEncoding`.

## Character Encoding Feature Attributes

To obtain the attributes of the character encoding supported by the handheld's ROM, request the value of the `sysFtrNumCharEncodingFlags` feature. You do this by calling [FtrGet\(\)](#) as follows:

---

```
err = FtrGet(sysFtrCreator, sysFtrNumEncodingFlags, &value);
```

---

Use the following bit masks to interpret value:

| Constant                                | Value                   | Description                                                                                 |
|-----------------------------------------|-------------------------|---------------------------------------------------------------------------------------------|
| <code>charEncodingOnlySingleByte</code> | <code>0x00000001</code> | The character encoding consists only of single-byte characters.                             |
| <code>charEncodingHasDoubleByte</code>  | <code>0x00000002</code> | The character encoding contains one or more double-byte characters.                         |
| <code>charEncodingHasLigatures</code>   | <code>0x00000004</code> | The character encoding has ligatures.                                                       |
| <code>charEncodingRightToLeft</code>    | <code>0x00000008</code> | The character encoding supports a writing system that primarily renders text right-to-left. |

## Character Attributes

The following constants define the flags that identify various character attributes. These replace the old flags defined in `CharAttr.h`, but are bit-compatible.

---

**NOTE:** `TextMgr.h` defines a set of functions and macros that can be used determine a character's attributes. These include [`TxtCharIsAlpha\(\)`](#), [`TxtCharIsCntrl\(\)`](#), and [`TxtCharIsValid\(\)`](#).

---

| Constant                 | Value               | Description                               |
|--------------------------|---------------------|-------------------------------------------|
| <code>charAttr_XA</code> | <code>0x0200</code> | Extra alphabetic                          |
| <code>charAttr_XS</code> | <code>0x0100</code> | Extra space                               |
| <code>charAttr_BB</code> | <code>0x0080</code> | BEL, BS, etc.                             |
| <code>charAttr_CN</code> | <code>0x0040</code> | CR, FF, HT, NL, VT                        |
| <code>charAttr_DI</code> | <code>0x0020</code> | '0'-'9'                                   |
| <code>charAttr_LO</code> | <code>0x0010</code> | 'a'-'z' and lowercase extended characters |
| <code>charAttr_PU</code> | <code>0x0008</code> | Punctuation                               |
| <code>charAttr_SP</code> | <code>0x0004</code> | Space                                     |
| <code>charAttr_UP</code> | <code>0x0002</code> | 'A'-'Z' and uppercase extended characters |
| <code>charAttr_XD</code> | <code>0x0001</code> | '0'-'9', 'A'-'F', 'a'-'f'                 |

These character attribute flags can be combined in various ways. `TextMgr.h` defines a number of standard combinations:

## Text Manager

### Character Sizes

---

| Constant                   | Value                                                                                            | Description                     |
|----------------------------|--------------------------------------------------------------------------------------------------|---------------------------------|
| <code>charAttrPrint</code> | <code>(charAttr_DI   charAttr_LO   charAttr_PU   charAttr_SP   charAttr_UP   charAttr_XA)</code> | Printable characters            |
| <code>charAttrSpace</code> | <code>(charAttr_CN   charAttr_SP   charAttr_XS)</code>                                           | Whitespace characters           |
| <code>charAttrAlNum</code> | <code>(charAttr_DI   charAttr_LO   charAttr_UP   charAttr_XA)</code>                             | Alphanumeric characters         |
| <code>charAttrAlpha</code> | <code>(charAttr_LO   charAttr_UP   charAttr_XA)</code>                                           | Alphabetic characters           |
| <code>charAttrCntrl</code> | <code>(charAttr_BB   charAttr_CN)</code>                                                         | Control characters              |
| <code>charAttrGraph</code> | <code>(charAttr_DI   charAttr_LO   charAttr_PU   charAttr_UP   charAttr_XA)</code>               | Printable, non-space characters |
| <code>charAttrDelim</code> | <code>(charAttr_SP   charAttr_PU)</code>                                                         | Delimiters                      |

## Character Sizes

These constants can be useful when working with characters of varying sizes.

| Constant                    | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sizeof7BitChar</code> | 1     | The size, in bytes, of a 7-bit character. In C, characters are treated like integers: <code>sizeof(0x0D) == 2</code> (as is <code>sizeof('a')</code> , <code>sizeof('\0')</code> , and <code>sizeof(chrNull)</code> ). Because of this, it's safest to use the <code>sizeof7BitChar</code> macro to document buffer size and string length calculations. Note that this can only be used with low-ASCII characters, as anything else might be the high byte of a double-byte character. |
| <code>maxCharBytes</code>   | 3     | Maximum size a single <code>WChar</code> character will occupy in a text string.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Text Manager Functions

### **TxtByteAttr Function**

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |                                |                                                                                  |                              |                                                                                             |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--------------------------------|----------------------------------------------------------------------------------|------------------------------|---------------------------------------------------------------------------------------------|
| <b>Purpose</b>                 | Return the possible locations of a given byte within a multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |                                |                                                                                  |                              |                                                                                             |
| <b>Declared In</b>             | TextMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |                                |                                                                                  |                              |                                                                                             |

| <b>Returns</b>                 | Returns a byte with one or more of the following bits set:<br><br>byteAttrFirst           First byte of multi-byte character.<br><br>byteAttrLast            Last byte of multi-byte character.<br><br>byteAttrMiddle          Middle byte of multi-byte character.<br><br>byteAttrSingle          Single-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |                                |                                                                                  |                              |                                                                                             |
| <b>Comments</b>                | <p>If <i>inByte</i> is valid in more than one location of a character, multiple return bits are set. For example, 0x40 in the Shift JIS character encoding is valid as a single-byte character and as the low-order byte of a double-byte character. Thus, the return value for <code>TxtByteAttr(0x40)</code> on a Shift JIS system has both the <code>byteAttrSingle</code> and <code>byteAttrLast</code> bits set. <code>TextMgr.h</code> defines two constants that represent double-byte encoding combinations:</p> <table><tr><td><code>byteAttrSingleLow</code></td><td>Either a single-byte character or the low-order byte of a double-byte character.</td></tr><tr><td><code>byteAttrHighLow</code></td><td>Either the first byte of a multi-byte character or the last byte of a multi-byte character.</td></tr></table> <p>Every byte in a stream of double-byte data must be either a single byte, a single/low byte (<code>byteAttrSingleLow</code>), or a high/low byte (<code>byteAttrHighLow</code>).</p> |  | <code>byteAttrSingleLow</code> | Either a single-byte character or the low-order byte of a double-byte character. | <code>byteAttrHighLow</code> | Either the first byte of a multi-byte character or the last byte of a multi-byte character. |
| <code>byteAttrSingleLow</code> | Either a single-byte character or the low-order byte of a double-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |                                |                                                                                  |                              |                                                                                             |
| <code>byteAttrHighLow</code>   | Either the first byte of a multi-byte character or the last byte of a multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |                                |                                                                                  |                              |                                                                                             |

Text manager functions that need to determine the byte positioning of a character use `TxtByteAttr` to do so. You rarely need to use this function yourself.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueByteAttr`. For more information, see [Chapter 75](#), “[PalmOSGlue Library](#).”

## **TxtCaselessCompare Function**

**Purpose** Perform a case-insensitive comparison of two text buffers.

**Declared In** `TextMgr.h`

**Prototype**

```
Int16 TxtCaselessCompare (const Char* s1,
                          UInt16 s1Len, UInt16* s1MatchLen,
                          const Char* s2,
                          UInt16 s2Len, UInt16* s2MatchLen)
```

**Parameters**

- *s1*  
Pointer to the first text buffer to compare.
- *s1Len*  
Length in bytes of the text pointed to by *s1*.
- ← *s1MatchLen*  
Points to the offset of the first character in *s1* that determines the sort order. Pass NULL for this parameter if you don't need to know this number.
- *s2*  
Pointer to the second text buffer to compare.
- *s2Len*  
Length in bytes of the text pointed to by *s2*.
- ← *s2MatchLen*  
Points to the offset of the first character in *s2* that determines the sort order. Pass NULL for this parameter if you don't need to know this number.

**Returns** Returns one of the following values:

- < 0 If *s1* occurs before *s2* in alphabetical order.

- > 0     If s1 occurs after s2 in alphabetical order.
- 0        If the two substrings that were compared are equal.

**Comments**     In certain character encodings (such as Shift JIS), one character may be accurately represented as either a single-byte character or a multi-byte character. TxtCaselessCompare accurately matches a single-byte character with its multi-byte equivalent. For this reason, the values returned in s1MatchLen and s2MatchLen are not always equal.

You must make sure that the parameters s1 and s2 point to the start of a valid character. That is, they must point to the first byte of a multi-byte character or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility**     Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCaselessCompare. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

In Palm OS 4.0, the TxtCaselessCompare function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameters.

**See Also**     [StrCaselessCompare\(\)](#), [TxtCompare\(\)](#), [StrCompare\(\)](#)

## **TxtCharAttr Function**

**Purpose**     Return a character's attributes.

**Declared In**     TextMgr.h

**Prototype**     UInt16 TxtCharAttr (WChar inChar)

**Parameters**     → *inChar*  
                          Any valid character.

**Returns**     Returns a 16-bit unsigned value with any of the following bits set:

|               |                              |
|---------------|------------------------------|
| charAttrPrint | Printable                    |
| charAttrSpace | Blank space, tab, or newline |

## Text Manager

### *TxtCharBounds*

---

|                            |                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>charAttrAlNum</code> | Alphanumeric                                                                                                   |
| <code>charAttrAlpha</code> | Alphabetic                                                                                                     |
| <code>charAttrCntrl</code> | Control character                                                                                              |
| <code>charAttrGraph</code> | Character that appears on the screen; that is, is not whitespace, a control character, or a virtual character. |
| <code>charAttrDelim</code> | Word delimiter (whitespace or punctuation).                                                                    |

**Comments** The character passed to this function must be a valid character given the system encoding.

This function is used in the text manager's character attribute macros ([TxtCharIsAlNum\(\)](#), [TxtCharIsCntrl\(\)](#), and so on). The macros perform operations analogous to the standard C functions `isPunct`, `isPrintable`, and so on. Usually, you'd use one of these macros instead of calling `TxtCharAttr` directly.

To obtain attributes specific to a given character encoding, use [TxtCharXAttr\(\)](#).

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharAttr`. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

**See Also** [TxtCharIsValid\(\)](#)

## TxtCharBounds Function

**Purpose** Return the boundaries of a character containing the byte at a specified offset in a string.

**Declared In** `TextMgr.h`

**Prototype**

```
WChar TxtCharBounds (const Char* inText,
                    UInt32 inOffset, UInt32* outStart,
                    UInt32* outEnd)
```

**Parameters**  $\rightarrow$  *inText*  
Pointer to the text buffer to search.

→ *inOffset*

A valid offset into the buffer *inText*. This location may contain a byte in any position (start, middle, or end) of a multi-byte character.

← *outStart*

Points to the starting offset of the character containing the byte at *inOffset*.

← *outEnd*

Points to the ending offset of the character containing the byte at *inOffset*.

**Returns** Returns the character located between the offsets *outStart* and *outEnd*.

**Comments** Use this function to determine the boundaries of a character in a string or text buffer.

If the byte at *inOffset* is valid in more than one location of a character, the function must search back toward the beginning of the text buffer until it finds an unambiguous byte to determine the appropriate boundaries. For this reason, *TxtCharBounds* is often slow and should be used only where needed.

You must make sure that the parameter *inText* points to the beginning of the string. That is, if the string begins with a multi-byte character, *inText* must point to the first byte of that character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call *TxtGlueCharBounds*. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

## TxtCharEncoding Function

**Purpose** Return the minimum encoding required to represent a character.

**Declared In** *TextMgr.h*

**Prototype** `CharEncodingType TxtCharEncoding (WChar inChar)`

**Parameters** → *inChar*

A valid character.

- Returns** A [CharEncodingType](#) value that indicates the minimum encoding required to represent `inChar`. If the character isn't recognizable, `charEncodingUnknown` is returned.
- Comments** The minimum encoding is the encoding that represents the fewest number of characters while still containing the character specified in `inChar`. For example, if the character is a blank or a tab character, the minimum encoding is `charEncodingAscii` because these characters can be represented in single-byte ASCII. If the character is a ü, the minimum encoding is `charEncodingISO8859_1`.
- This function is used by [TxtStrEncoding\(\)](#), which is the function that most applications should use to determine the character encoding for tagging text (for instance, for email).
- Use [TxtMaxEncoding\(\)](#) to determine the order of encodings.
- Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharEncoding`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)
- Palm OS only supports a single character encoding at a time. Because of this, the result of `TxtCharEncoding` is always logically equal to or less than the encoding used on the current system. That is, you'll only receive a return value of `charEncodingISO8859_1` if you're running on a US or European system and you pass a non-ASCII character.
- See Also** [TxtStrEncoding\(\)](#), [TxtMaxEncoding\(\)](#)

## TxtCharIsAlNum Macro

- Purpose** Indicates if the character is alphanumeric.
- Declared In** `TextMgr.h`
- Prototype** `#define TxtCharIsAlNum (ch)`
- Parameters** `→ ch`  
A valid character.
- Returns** Returns `true` if the character is a letter in an alphabet or a numeric digit, `false` otherwise.

- Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsAlNum. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)
- See Also** [TxtCharIsDigit\(\)](#), [TxtCharIsAlpha\(\)](#)

## **TxtCharIsAlpha Macro**

- Purpose** Indicates if a character is a letter in an alphabet.
- Declared In** TextMgr.h
- Prototype**

```
#define TxtCharIsAlpha (ch)
```
- Parameters**  $\rightarrow ch$   
A valid character.
- Returns** Returns true if the character is a letter in an alphabet, false otherwise.
- Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsAlpha. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)
- See Also** [TxtCharIsAlNum\(\)](#), [TxtCharIsLower\(\)](#), [TxtCharIsUpper\(\)](#)

## **TxtCharIsCntrl Macro**

- Purpose** Indicates if a character is a control character.
- Declared In** TextMgr.h
- Prototype**

```
#define TxtCharIsCntrl (ch)
```
- Parameters**  $\rightarrow ch$   
A valid character.
- Returns** Returns true if the character is a non-printable character, such as the bell character or a carriage return; false otherwise.
- Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsCntrl. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

## **TxtCharIsDelim Macro**

|                      |                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is a delimiter.                                                                                                                                                                                                                                                                 |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>#define TxtCharIsDelim (ch)</code>                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>→ ch</code><br>A valid character.                                                                                                                                                                                                                                                                  |
| <b>Returns</b>       | Returns <code>true</code> if the character is a word delimiter (whitespace or punctuation), <code>false</code> otherwise.                                                                                                                                                                                |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueCharIsDelim</code> . For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a> |

## **TxtCharIsDigit Macro**

|                      |                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if the character is a decimal digit.                                                                                                                                                                                                                                                           |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>#define TxtCharIsDigit (ch)</code>                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>→ ch</code><br>A valid character.                                                                                                                                                                                                                                                                  |
| <b>Returns</b>       | Returns <code>true</code> if the character is 0 through 9, <code>false</code> otherwise.                                                                                                                                                                                                                 |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueCharIsDigit</code> . For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a> |

## **TxtCharIsGraph Macro**

|                      |                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is a graphic character.                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>     | #define TxtCharIsGraph (ch)                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | → <i>ch</i><br>A valid character.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Returns</b>       | Returns true if the character is a graphic character, false otherwise.                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>      | <p>A graphic character is any character visible on the screen, in other words, letters, digits, and punctuation marks. A blank space is not a graphic character because it is not visible.</p> <p>This macro differs from <a href="#">TxtCharIsPrint()</a> in that it returns false if the character is whitespace. TxtCharIsPrint returns true if the character is whitespace.</p> |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsGraph. For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a>                                                                                          |

## **TxtCharIsHardKey Macro**

|                      |                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns true if the character is one of the hard keys on the device.                                                           |
| <b>Declared In</b>   | TextMgr.h                                                                                                                      |
| <b>Prototype</b>     | #define TxtCharIsHardKey (m, ch)                                                                                               |
| <b>Parameters</b>    | → <i>m</i><br>The modifier keys from the <a href="#">keyDownEvent</a> .<br>→ <i>ch</i><br>The character from the keyDownEvent. |
| <b>Returns</b>       | true if the character is one of the built-in hard keys on the device, false otherwise.                                         |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present.                                                            |
| <b>See Also</b>      | <a href="#">ChrIsHardKey()</a>                                                                                                 |

## **TxtCharIsHex Macro**

|                      |                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is a hexadecimal digit.                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | <code>#define TxtCharIsHex (ch)</code>                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>→ ch</code><br>A valid character.                                                                                                                                                                                                                                                                |
| <b>Returns</b>       | Returns <code>true</code> if the character is a hexadecimal digit from 0 to F, <code>false</code> otherwise.                                                                                                                                                                                           |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. ## **TxtCharIsPrint Macro**

|                      |                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is printable.                                                                                                                                                                                                                                                               |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | #define TxtCharIsPrint (ch)                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>    | → <i>ch</i><br>A valid character.                                                                                                                                                                                                                                                                    |
| <b>Returns</b>       | Returns true if the character is not a control character, false otherwise.                                                                                                                                                                                                                           |
| <b>Comments</b>      | <p>This macro differs from <a href="#">TxtCharIsGraph()</a> in that it returns true if the character is whitespace. TxtCharIsGraph returns false if the character is whitespace.</p> <p>If you are using a debug ROM and you pass a virtual character to this macro, a fatal alert is generated.</p> |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsPrint. For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a>           |
| <b>See Also</b>      | <a href="#">TxtCharIsValid()</a>                                                                                                                                                                                                                                                                     |

## **TxtCharIsPunct Macro**

|                      |                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is a punctuation mark.                                                                                                                                                                                                                                            |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>     | #define TxtCharIsPunct (ch)                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | → <i>ch</i><br>A valid character.                                                                                                                                                                                                                                                          |
| <b>Returns</b>       | Returns true if the character is a punctuation mark, false otherwise.                                                                                                                                                                                                                      |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. ## **TxtCharIsUpper Macro**

|                      |                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Indicates if a character is an uppercase letter.                                                                                                                                                                                                                                                         |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>#define TxtCharIsUpper (ch)</code>                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>→ ch</code><br>A valid character.                                                                                                                                                                                                                                                                  |
| <b>Returns</b>       | Returns <code>true</code> if the character is an uppercase letter, <code>false</code> otherwise.                                                                                                                                                                                                         |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueCharIsUpper</code> . For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a> |
| <b>See Also</b>      | <a href="#">TxtCharIsAlpha()</a> , <a href="#">TxtCharIsLower()</a>                                                                                                                                                                                                                                      |

## TxtCharIsValid Function

|                      |                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Determine whether a character is valid character given the Palm OS character encoding.                                                                                                                                                                                                              |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>     | Boolean TxtCharIsValid (WChar inChar)                                                                                                                                                                                                                                                               |
| <b>Parameters</b>    | → <i>inChar</i><br>A character.                                                                                                                                                                                                                                                                     |
| <b>Returns</b>       | Returns true if inChar is a valid character; false if inChar is not a valid character.                                                                                                                                                                                                              |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharIsValid. For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a> |
| <b>See Also</b>      | <a href="#">TxtCharAttr()</a> , <a href="#">TxtCharIsPrint()</a>                                                                                                                                                                                                                                    |

## TxtCharSize Function

|                      |                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the number of bytes required to store the character in a string.                                                                                                                                                                                                                                                                     |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | UInt16 TxtCharSize (WChar inChar)                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | → <i>inChar</i><br>A valid character.                                                                                                                                                                                                                                                                                                       |
| <b>Returns</b>       | The number of bytes required to store the character in a string.                                                                                                                                                                                                                                                                            |
| <b>Comments</b>      | Although character variables are always two-byte long WChar values, in some character encodings such as Shift-JIS, characters in strings are represented by a mix of one or more bytes per character. If the character can be represented by a single byte (its high-order byte is 0), it is stored in a string as a single-byte character. |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharSize. For more information, see <a href="#">Chapter 75, “PalmOSGlue Library.”</a>                                            |
| <b>See Also</b>      | <a href="#">TxtCharBounds()</a>                                                                                                                                                                                                                                                                                                             |

## **TxtCharWidth Function**

|                      |                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the width required to display the specified character in the current font. If the specified character does not exist within the current font, the missing character symbol is substituted. |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                                                            |
| <b>Prototype</b>     | <code>Int16 TxtCharWidth (WChar inChar)</code>                                                                                                                                                    |
| <b>Parameters</b>    | <code>→ inChar</code><br>A valid character.                                                                                                                                                       |
| <b>Returns</b>       | Returns the width of the specified character (in pixels).                                                                                                                                         |
| <b>Comments</b>      | Use <a href="#">FntWCharWidth()</a> or <code>FntGlueWCharWidth</code> instead of this routine.                                                                                                    |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present.                                                                                                                         |

## **TxtCharXAttr Function**

|                    |                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the extended attribute bits for a character.                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>TextMgr.h</code>                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <code>UInt16 TxtCharXAttr (WChar inChar)</code>                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <code>→ inChar</code><br>A valid character.                                                                                                                                                                                                                                          |
| <b>Returns</b>     | Returns an unsigned 16-bit value with one or more extended attribute bits set. For specific return values, look in the header files that are specific to certain character encodings ( <code>CharLatin.h</code> or <code>CharShiftJIS.h</code> ).                                    |
| <b>Comments</b>    | To interpret the results, you must know the character encoding being used. Use <a href="#">FtrGet()</a> with <code>sysFtrNumEncoding</code> as the feature number to determine the character encoding. This returns one of the <a href="#">CharEncodingType</a> values. For example: |

---

```
WChar ch;
UInt16 attr;
UInt32 encoding;
...
attr = TxtCharXAttr(ch);
if (FtrGet(sysFtrCreator, sysFtrNumEncoding,
    &encoding) != errNone)
```

```
encoding = charEncodingPalmLatin;  
if (encoding == charEncodingUTF8) {  
}
```

---

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCharXAttr. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharAttr\(\)](#)

## **TxtCompare Function**

**Purpose** Performs a case-sensitive comparison of all or part of two text buffers.

**Declared In** TextMgr.h

**Prototype** `Int16 TxtCompare (const Char* s1, UInt16 s1Len,  
                  UInt16* s1MatchLen, const Char* s2,  
                  UInt16 s2Len,  
                  UInt16* s2MatchLen)`

**Parameters**

- *s1*  
Pointer to the first text buffer to compare.
- *s1Len*  
The length in bytes of the text pointed to by *s1*.
- ← *s1MatchLen*  
Points to the offset of the first character in *s1* that determines the sort order. Pass NULL for this parameter if you don't need to know this number.
- *s2*  
Pointer to the second text buffer to compare.
- *s2Len*  
The length in bytes of the text pointed to by *s2*.
- ← *s2MatchLen*  
Points to the offset of the first character in *s2* that determines the sort order. Pass NULL for this parameter if you don't need to know this number.

**Returns** Returns one of the following values:

- < 0     If s1 occurs before s2 in alphabetical order.
- > 0     If s1 occurs after s2 in alphabetical order.
- 0        If the two substrings that were compared are equal.

**Comments**     This function performs a case-sensitive comparison. If you want to perform a case-insensitive comparison, use [TxtCaselessCompare\(\)](#).

The s1MatchLen and s2MatchLen parameters are not as useful for the TxtCompare function as they are for the TxtCaselessCompare function because TxtCompare implements a multi-pass sort algorithm. (See the Compatibility section below for further details.) For example, comparing the string “celery” with the string “Cauliflower” returns a positive value to indicate that “celery” sorts after “Cauliflower,” and it returns a match length of 1 to indicate that the second letter determines the sort order (“e” comes after “a”). However, because TxtCompare ultimately does a case-sensitive comparison, comparing the string “c” to the string “C” produces a negative result and a match length of 0.

In certain character encodings (such as Shift JIS), one character may be accurately represented as either a single-byte character or a multi-byte character. TxtCompare accurately matches a single-byte character with its multi-byte equivalent. For this reason, the values returned in s1MatchLen and s2MatchLen are not always equal.

You must make sure that the parameters s1 and s2 point to the start of a valid character. That is, they must point to the first byte of a multi-byte character or they must point to a single-byte character; if they don’t, results are unpredictable.

**Compatibility**     Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueCompare. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

Prior to Palm OS 4.0, TxtCompare and [StrCompare\(\)](#) only performed one level of comparison and returned as soon as they found two unequal characters. For example, if you compared the string “celery” with the string “Cauliflower,” both functions

returned a value indicating that “celery” should appear before “Cauliflower” because they sorted “c” before “C.”

In Palm OS 4.0, `StrCompare` calls `TxtCompare`, and `TxtCompare` performs a comparison using up to six comparison tables for sorting with increasing precision. As a result, in Palm OS 4.0 and higher, `TxtCompare` sorts “Cauliflower” before “celery.” The `TxtGlueCompare` function uses a two-pass sort on pre-4.0 devices, which will also sort “Cauliflower” before “celery.”

Palm OS 4.0 sorting of Shift-JIS characters attempts to duplicate the sorting algorithm described by the JIS standard.

In Palm OS 4.0, the `TxtCompare` function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameters.

**See Also**    [`StrCompare\(\)`](#), [`TxtFindString\(\)`](#)

## **TxtConvertEncoding Function**

**Purpose**    Convert a text buffer from one character encoding to another.

**Declared In**    `TextMgr.h`

**Prototype**    `Err TxtConvertEncoding (Boolean newConversion,  
                              TxtConvertStateType *ioStateP,  
                              const Char *srcTextP, UInt16 *ioSrcBytes,  
                              CharEncodingType srcEncoding, Char *dstTextP,  
                              UInt16 *ioDstBytes,  
                              CharEncodingType dstEncoding,  
                              const Char *substitutionStr,  
                              UInt16 substitutionLen)`

**Parameters**     $\rightarrow$  *newConversion*  
                  Set to true if this function call is starting a new conversion, or false if this function call is a continuation of a previous conversion.

$\leftrightarrow$  *ioStateP*  
                  If *newConversion* is false, this parameter must point to a [`TxtConvertStateType`](#) structure containing the same data used for the previous invocation. If *newConversion* is true and no subsequent calls are planned, this parameter can be NULL.

→ *srcTextP*

Pointer to the source text buffer. If `newConversion` is `true`, this must point to the start of a text buffer. If `newConversion` is `false`, it may point to a location in the middle of a text buffer. In either case, it must point to an inter-character boundary.

↔ *ioSrcBytes*

A pointer to the length, in bytes, of the text starting at *srcTextP* that needs to be converted. Upon return, *\*ioSrcBytes* contains the number of bytes successfully processed.

→ *srcEncoding*

The character encoding that the source text uses. This should be one of the [Character Encoding Constants](#).

→ *dstTextP*

Pointer to the destination text buffer, or `NULL` if you only want to know how large the destination text buffer must be (the minimum size is returned in *\*ioDstBytes*). If not `NULL`, *dstTextP* should point to a location where `TxtConvertEncoding` can begin writing.

→ *ioDstBytes*

A pointer to the length, in bytes, of *dstTextP*. Upon return, *\*ioDstBytes* contains the number of bytes required to represent the source text in the new encoding.

→ *dstEncoding*

The character encoding to which to convert *srcTextP*. This should be one of the constants documented in “[Character Encoding Constants](#)” on page 737. Note that the encoding can be modified, giving you greater control over the conversion process: see “[Character Encoding Constant Modifiers](#)” on page 961.

→ *substitutionStr*

A string to be substituted for any invalid or unconvertible characters that occur in the source text. This string must already be in the destination encoding. If `NULL`, `TxtGlueConvertEncoding` immediately returns if it encounters an invalid character.

→ *substitutionLen*

The number of bytes in *substitutionStr*, not including the terminating null byte.

**Returns** Returns `errNone` upon success or one of the following if an error occurs:

`txtErrConvertOverflow`

The destination buffer is not large enough to contain the converted text.

`txtErrConvertUnderflow`

The end of the source buffer contains a partial character.

`txtErrMalformedText`

An error in the source text encoding has been discovered.

`txtErrNoCharMapping`

The device does not contain a mapping between the source and destination encodings for at least one of the characters in *srcTextP*, and there is no substitution string.

`txtErrUnknownEncoding`

One of the specified encodings is unknown or can't be handled, or the function is being called on a handheld running a version of Palm OS prior to 3.5.

`txtErrUnknownEncodingFallbackCopy`

Either the source or destination encoding is unknown, and the best fit flag was set in the destination encoding. Before returning this error code, `TxtConvertEncoding` copies anything that is 7-bit ASCII from the source text buffer to the destination text buffer.

**Comments** This function converts *ioSrcBytes* of text in *srcTextP* from the *srcEncoding* to the *dstEncoding* character encoding and returns the result in *dstTextP*.

`TxtConvertEncoding` can convert between the following “built-in” encodings and the device encoding:

- UTF-8
- UTF-16, UTF-16BE, UTF-16LE, UCS-2
- UTF-32, UTF-32BE, UTF-32LE, UCS-4<sup>2</sup>

It can also support a variety of encodings that are locale dependent. The only locale for which `TxtConvertEncoding` supports

additional encodings is simplified Chinese in Palm OS versions that support simplified Chinese. The additional source encodings supported for the simplified Chinese locale are:

- GB2312
- GBK
- ISO2022-CN
- Big5
- Big5+HKSCS
- CP1252
- ISO8859-1
- US ASCII (ISO646)
- GSM

The additional destination encodings supported for the simplified Chinese locale are:

- GB2312
- GBK
- ISO2022-CN
- GSM

If the `charEncodingDstBestFitFlag` is supported (see “[Character Encoding Constant Modifiers](#)” on page 961) but is *not* set in the destination encoding passed to the function, and you specify an unsupported character encoding for either the source or the destination buffer, `TxtConvertEncoding` returns `txtErrUnknownEncoding`.

You can retrieve the device’s encoding using the following function:

---

```
FtrGet(sysFtrCreator, sysFtrNumEncoding,  
       &encoding)
```

---

If you’re converting text that was received from the Internet, the encoding’s name is passed along with the text data. Use the

- 
2. UTF-32, UTF-32BE, UTF-32LE, and UCS-4 are only built into handhelds running a version of Palm OS that supports simplified Chinese.

[TxtNameToEncoding\(\)](#) function to convert the name to a [CharEncodingType](#) value.

The `dstTextP` buffer must be large enough to hold the result of converting `srcTextP` to the specified encoding. You can pass `NULL` for the `dstTextP` parameter to determine the required length of the buffer before actually doing the conversion; the required length is returned in `ioDstBytes`.

If the function encounters an inconvertible character in the source text, it puts `substitutionStr` in the destination buffer in that character's place and continues the conversion. When the conversion is complete, it returns `txtErrNoCharMapping` to indicate that an error occurred (assuming that no other higher-priority error occurred during the conversion). If `substitutionStr` is `NULL`, the function stops the conversion and immediately returns `txtErrNoCharMapping`. `ioSrcBytes` is set to the offset of the inconvertible character, `dstTextP` contains the converted string up to that point, and `ioDstBytes` contains the size of the converted text. You can examine the character at `ioSrcBytes` and choose to move past it and continue the conversion. Follow the rules for making repeated calls to `TxtConvertEncoding` as described in the next paragraph.

You can make repeated calls to `TxtConvertEncoding` in a loop if you only want to convert part of the input buffer at a time. When you make repeated calls to this function, the first call should use `true` for `newConversion`, and `srcTextP` should point to the start of the text buffer. All subsequent calls should use the following values:

`newConversion`  
    `false`.

`ioStateP`

    The same data that was returned by the previous invocation.

`srcTextP`

    The location where this call should begin converting. Typically, this would be the previous `srcTextP` plus the number of bytes returned in `ioSrcBytes`.

    If you are skipping over an inconvertible character, `srcTextP` must point to the character after that location.

$\leftrightarrow$  *ioSrcBytes*

The number of bytes that this function call should convert.

*dstTextP*

A pointer to a location where this function can begin writing the converted string. You might choose to have each function call write to a different destination buffer. To have successive calls write to the same buffer, pass the previous *dstTextP* plus the number of bytes returned in *ioDstBytes* each time.

*ioDstBytes*

The number of bytes available for output in the *dstTextP* buffer. In other words, the number of bytes remaining.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on Palm OS 3.5, link with the PalmOSGlue library and call [TxtGlueConvertEncoding\(\)](#). For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

In Palm OS versions that do not support simplified Chinese, the focus of `TxtConvertEncoding` is to convert between Unicode-encoded text and the device's character encoding. For this reason, `TxtConvertEncoding` can only handle conversions between the device's encoding and one of UTF-8, UCS-2, UTF-16LE, or UTF-16BE. If you specify any other character encoding for either the source or the destination buffer, the error code `txtErrUnknownEncoding` is returned.

## TxtEncodingName Function

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Obtain a character encoding's name.                                                                                           |

| <b>See Also</b>      | <a href="#">TxtNameToEncoding()</a>                                                                                                                                                                                                                                                                                     |

## TxtFindString Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Perform a case-insensitive search for a string in another string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | TextMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | Boolean TxtFindString (const Char* inSourceStr,<br>const Char* inTargetStr, UInt32* outPos,<br>UInt16* outLength)                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p>→ <i>inSourceStr</i><br/>    Pointer to the string to be searched.</p> <p>→ <i>inTargetStr</i><br/>    Prepared version of the string to be found. This string should either be passed directly from the strToFind field in the <a href="#">sysAppLaunchCmdFind</a> launch code's parameter block or it should be prepared using the PalmOSGlue function <a href="#">TxtGluePrepFindString()</a>.</p> <p>← <i>outPos</i><br/>    Pointer to the offset of the match in inSourceStr.</p> <p>← <i>outLength</i><br/>    Pointer to the length in bytes of the matching text.</p> |
| <b>Returns</b>     | <p>Returns true if the function finds inTargetStr within inSourceStr; false otherwise.</p> <p>If found, the values pointed to by the outPos and outLength parameters are set to the starting offset and the length of the matching text. If not found, the values pointed to by outPos and outLength are set to 0.</p>                                                                                                                                                                                                                                                            |

## Text Manager

### *TxtGetChar*

---

The search that `TxtFindString` performs is locale-dependent. On most ROMs with Latin-based encodings, `TxtFindString` returns `true` only if the string is at the beginning of a word. On Shift-JIS encoded ROMs, `TxtFindString` returns `true` if the string is located anywhere in the word.

**Comments** Use this function instead of [FindStrInStr\(\)](#) to support the global system find facility. This function contains an extra parameter, `outLength`, to specify the length of the text that matched. Pass this value to [FindSaveMatch\(\)](#) in the `appCustom` parameter. Then when your application receives `sysAppLaunchCmdGoTo`, the `matchCustom` field contains the length of the matching text. You use the length of matching text to highlight the match within the selected record.

You must make sure that the parameters `inSourceStr` and `inTargetStr` point to the start of a valid character. That is, they must point to the first byte of a multi-byte character, or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the `PalmOSGlue` library and call [TxtGlueFindString\(\)](#). For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

**See Also** [TxtCaselessCompare\(\)](#)

## TxtGetChar Function

**Purpose** Retrieve the character starting at the specified offset within a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `WChar TxtGetChar (const Char* inText,  
                  UInt32 inOffset)`

**Parameters**  $\rightarrow$  `inText`  
Pointer to the text buffer to be searched.

|                      |                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>→ <i>inOffset</i></p> <p>A valid offset into the buffer <i>inText</i>. This offset must point to an inter-character boundary.</p>                                                                                                                                                                                             |
| <b>Returns</b>       | Returns the character at <i>inOffset</i> in <i>inText</i> .                                                                                                                                                                                                                                                                      |
| <b>Comments</b>      | You must make sure that the parameter <i>inText</i> points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueGetChar</code> . For more information, see <a href="#">Chapter 75</a> , " <a href="#">PalmOSGlue Library</a> ." |
| <b>See Also</b>      | <a href="#">TxtGetNextChar()</a> , <a href="#">TxtSetNextChar()</a>                                                                                                                                                                                                                                                              |

## TxtGetNextChar Function

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Retrieve the character starting at the specified offset within a text buffer.                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <pre>UInt16 TxtGetNextChar (const Char* inText,<br/>                        UInt32 inOffset, WChar* outChar)</pre>                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p>→ <i>inText</i></p> <p>Pointer to the text buffer to be searched.</p> <p>→ <i>inOffset</i></p> <p>A valid offset into the buffer <i>inText</i>. This offset must point to an inter-character boundary.</p> <p>← <i>outChar</i></p> <p>The character at <i>inOffset</i> in <i>inText</i>. Pass NULL for this parameter if you don't need the character returned.</p> |
| <b>Returns</b>     | Returns the size in bytes of the character at <i>inOffset</i> . If <i>outChar</i> is not NULL upon entry, it points to the character at <i>inOffset</i> upon return.                                                                                                                                                                                                   |
| <b>Comments</b>    | You can use this function to iterate through a text buffer character-by-character in this way:                                                                                                                                                                                                                                                                         |

---

```
UInt16 i = 0;
WChar ch;
while (i < bufferLength) {
    i += TxtGetNextChar(buffer, i, &ch);
    //do something with ch.
}
```

---

You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetNextChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetChar\(\)](#), [TxtGetPreviousChar\(\)](#), [TxtSetNextChar\(\)](#)

## TxtGetPreviousChar Function

- Purpose** Retrieve the character before the specified offset within a text buffer.
- Declared In** `TextMgr.h`
- Prototype**

```
UInt16 TxtGetPreviousChar (const Char* inText,
                          UInt32 inOffset, WChar* outChar)
```
- Parameters**
- *inText*  
Pointer to the text buffer to be searched.
  - *inOffset*  
A valid offset into the buffer *inText*. This offset must point to an inter-character boundary.
  - ← *outChar*  
The character immediately preceding *inOffset* in *inText*. Pass NULL for this parameter if you don't need the character returned.
- Returns** Returns the size in bytes of the character preceding *inOffset* in *inText*. If *outChar* is not NULL upon entry, then it points to the character preceding *inOffset* upon return. Returns 0 if *inOffset* is at the start of the buffer (that is, *inOffset* is 0).

**Comments** You can use this function to iterate through a text buffer character-by-character in this way:

---

```
WChar ch;
/* Find the start of the character containing
the last byte. */
TxtCharBounds (buffer, bufferLength - 1,
&start, &end);
i = start;
while (i > 0) {
    i -= TxtGetPreviousChar(buffer, i, &ch);
    //do something with ch.
}
```

---

This function is often slower to use than [TxtGetNextChar\(\)](#) because it must determine the appropriate character boundaries if the byte immediately before the offset is valid in more than one location (start, middle, or end) of a multi-byte character. To do this, it must work backwards toward the beginning of the string until it finds an unambiguous byte.

You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetPreviousChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## **TxtGetTruncationOffset Function**

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the appropriate byte position for truncating a text buffer such that it is at most a specified number of bytes long. |
| <b>Declared In</b> | <code>TextMgr.h</code>                                                                                                      |
| <b>Prototype</b>   | <code>UInt32 TxtGetTruncationOffset (const Char* inText, UInt32 inOffset)</code>                                            |
| <b>Parameters</b>  | → <i>inText</i><br>Pointer to a text buffer.                                                                                |

## Text Manager

### *TxtGetWordWrapOffset*

---

→ *inOffset*

An offset into the buffer *inText*.

**Returns** Returns the appropriate byte offset for truncating *inText* at a valid inter-character boundary. The return value may be less than or equal to *inOffset*.

**Comments** You must make sure that the parameter *inText* points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetTruncationOffset`. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

## TxtGetWordWrapOffset Function

**Purpose** Locate an appropriate place for a line break in a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `UInt32 TxtGetWordWrapOffset (const Char *iTextP,  
                                  UInt32 iOffset)`

**Parameters** → *iTextP*  
                  Pointer to a text buffer.

→ *iOffset*  
                  Pointer to the offset where the search should begin. The search is performed backward starting from this offset.

**Returns** Returns the offset of a character that can begin on a new line (typically, the beginning of the word that contains *iOffset* or last word before *iOffset*). If an appropriate break could not be found, returns *iOffset*.

**Comments** The [FntWordWrap\(\)](#) and [FntWordWrapReverseNLines\(\)](#) functions call `TxtGetWordWrapOffset` to locate an appropriate place to break the text. The returned offset points to the character that should begin the next line.

This function starts at *iOffset* and works backward until it finds a character that typically occurs between words (for example, white

space or punctuation). Then it moves forward until it locates the character that begins a word (typically, a letter or number). Note that this function may return an offset value that is greater than the one passed in if the offset passed in occurs immediately before white space or in the middle of white space.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TxtWordBounds\(\)](#)

## **TxtMaxEncoding Function**

**Purpose** Return the higher of two encodings.

**Declared In** `TextMgr.h`

**Prototype** `CharEncodingType TxtMaxEncoding  
(CharEncodingType a, CharEncodingType b)`

**Parameters**

- *a*  
A character encoding to compare.
- *b*  
Another character encoding to compare.

**Returns** Returns the higher of *a* or *b*. One character encoding is higher than another if it is more specific. For example code page 1252 is “higher” than ISO 8859-1 because it represents more characters than ISO 8859-1.

**Comments** This function is used by [TxtStrEncoding\(\)](#) to determine the encoding required for a string.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueMaxEncoding`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharEncoding\(\)](#), [CharEncodingType](#)

## **TxtNameToEncoding Function**

- Purpose** Return an encoding's constant given its name.
- Declared In** `TextMgr.h`
- Prototype** `CharEncodingType TxtNameToEncoding  
(const Char *iEncodingName)`
- Parameters**  $\rightarrow$  *iEncodingName*  
One of the string constants containing the official name of an encoding. See `PalmLocale.h` for the complete set of string constants.
- Returns** Returns one of the [Character Encoding Constants](#). Returns `charEncodingUnknown` if the specified encoding could not be found.
- Comments** Use this function to convert a character encoding's name as received from an Internet application into the character encoding constant that some text manager functions require.
- This function properly converts aliases for a character encoding. For example, passing the strings "us-ascii", "ASCII", "cp367", and "IBM367" all return `charEncodingAscii`.
- The known character encodings are device-dependent. For example, a device with the Shift-JIS encoding will not know all of the aliases for Latin character encodings; however, it will know all of the aliases for Shift-JIS.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [TxtEncodingName\(\)](#)

## **TxtNextCharSize Macro**

- Purpose** Returns the size of the character starting at the specified offset within a text buffer.
- Declared In** `TextMgr.h`
- Prototype** `#define TxtNextCharSize (inText, inOffset)`
- Parameters**  $\rightarrow$  *inText*  
Pointer to the text buffer to be searched.

|                      |                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>→ <i>inOffset</i></p> <p>A valid offset into the buffer <i>inText</i>. This offset must point to an inter-character boundary.</p>                                                                                                                                                                                         |
| <b>Returns</b>       | Returns (as a <code>UInt16</code> ) the size in bytes of the character at <i>inOffset</i> .                                                                                                                                                                                                                                  |
| <b>Comments</b>      | You must make sure that the parameter <i>inText</i> points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.                                                                      |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueNextCharSize</code> . For more information, see <a href="#">Chapter 75</a> , " <a href="#">PalmOSGlue Library</a> ." |
| <b>See Also</b>      | <a href="#">TxtGetNextChar()</a>                                                                                                                                                                                                                                                                                             |

## TxtParamString Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Replace substrings within a string with the specified values.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>Char* TxtParamString (const Char* inTemplate,<br/>                      const Char* param0, const Char* param1,<br/>                      const Char* param2, const Char* param3)</pre>                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>inTemplate</i></p> <p>The string containing the substrings to replace.</p> <p>→ <i>param0</i></p> <p>String to replace <code>^0</code> with or <code>NULL</code>.</p> <p>→ <i>param1</i></p> <p>String to replace <code>^1</code> with or <code>NULL</code>.</p> <p>→ <i>param2</i></p> <p>String to replace <code>^2</code> with or <code>NULL</code>.</p> <p>→ <i>param3</i></p> <p>String to replace <code>^3</code> with or <code>NULL</code>.</p> |
| <b>Returns</b>     | Returns a pointer to a locked relocatable chunk in the dynamic heap that contains the appropriate substitutions.                                                                                                                                                                                                                                                                                                                                               |

**Comments** This function searches `inTemplate` for occurrences of the sequences `^0`, `^1`, `^2`, and `^3`. When it finds these, it replaces them with the corresponding string passed to this function. Multiple instances of each sequence will be replaced.

The replacement strings can also contain the substitution strings, provided they refer to a later parameter. That is, the `param0` string contain have references to `^1`, `^2`, and `^3`, the `param1` string can have references to `^2` and `^3`, and the `param2` string can have references to `^3`. Any other occurrences of the substitution strings in the replacement strings are ignored. For example, if `param3` is the string `"^0"`, any occurrences of `^3` in `inTemplate` are replaced with the string `"^0"`.

You must make sure that the parameter `inTemplate` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

`TxtParamString` allocates space for the returned string in the dynamic heap through a call to `MemHandleNew`, and then returns the result of calling `MemHandleLock` with this handle. Your code is responsible for freeing this memory when it is no longer needed.

**Compatibility** Implemented if [3.5 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueParamString`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtReplaceStr\(\)](#), [FrmCustomAlert\(\)](#)

## TxtPreviousCharSize Macro

**Purpose** Returns the size of the character before the specified offset within a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `#define TxtPreviousCharSize (inText, inOffset)`

**Parameters** `→ inText`  
Pointer to the text buffer.

→ *inOffset*

A valid offset into the buffer *inText*. This offset must point to an inter-character boundary.

**Returns** Returns (as a `UInt16`) the size in bytes of the character preceding *inOffset* in *inText*. Returns 0 if *inOffset* is at the start of the buffer (that is, *inOffset* is 0).

**Comments** You must make sure that the parameter *inText* points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

This macro is often slower to use than [TxtNextCharSize\(\)](#) because it must determine the appropriate character boundaries if the byte immediately before the offset is valid in more than one location (start, middle, or end) of a multi-byte character. To do this, it must work backwards toward the beginning of the string until it finds an unambiguous byte.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGluePreviousCharSize`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetPreviousChar\(\)](#)

## TxtReplaceStr Function

**Purpose** Replace a substring of a given format with another string.

**Declared In** `TextMgr.h`

**Prototype**

```
UInt16 TxtReplaceStr (Char* ioStr,
                     UInt16 inMaxLen, const Char* inParamStr,
                     UInt16 inParamNum)
```

**Parameters** ↔ *ioStr*

The string in which to perform the replacing.

→ *inMaxLen*

The maximum length in bytes that *ioStr* can become.

→ *inParamStr*

The string that *inParamNum* should be replaced with. If NULL, no changes are made.

## Text Manager

### *TxtSetNextChar*

---

→ *inParamNum*

A single-digit number (0 to 9).

**Returns** Returns the number of occurrences found and replaced.

Returns a fatal error message if *inParamNum* is greater than 9.

**Comments** This function searches *ioStr* for occurrences of the string *^inParamNum*, where *inParamNum* is any digit from 0 to 9. When it finds the string, it replaces it with *inParamStr*. Multiple instances will be replaced as long as the resulting string doesn't contain more than *inMaxLen* bytes, not counting the terminating null.

You can set the *inParamStr* parameter to NULL to determine the required length of *ioStr* before actually doing the replacing. *TxtReplaceStr* returns the number of occurrences it finds of *^inParamNum*. Multiply this value by the length of the *inParamStr* you intend to use to determine the appropriate length of *ioStr*.

You must make sure that the parameter *ioStr* points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call *TxtGlueReplaceStr*. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtSetNextChar Function

**Purpose** Set a character within a text buffer.

**Declared In** *TextMgr.h*

**Prototype** `UInt16 TxtSetNextChar (Char* ioText,  
                          UInt32 inOffset, WChar inChar)`

**Parameters** ↔ *ioText*  
                  Pointer to a text buffer.

→ *inOffset*  
                  A valid offset into the buffer *inText*. This offset must point to an inter-character boundary.

→ *inChar*

The character to replace the character at `inOffset` with.  
Must not be a virtual character.

**Returns** Returns the size of `inChar`.

**Comments** This function replaces the character in `ioText` at the location `inOffset` with the character `inChar`. Note that there must be enough space at `inOffset` to write the character.

You can use [TxtCharSize\(\)](#) to determine the size of `inChar`.

You must make sure that the parameter `ioText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueSetNextChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetNextChar\(\)](#)

## TxtStrEncoding Function

**Purpose** Return the encoding required to represent a string.

**Declared In** `TextMgr.h`

**Prototype** `CharEncodingType TxtStrEncoding  
(const Char* inStr)`

**Parameters** → *inStr*  
A string.

**Returns** A [CharEncodingType](#) value that indicates the encoding required to represent `inChar`. If any character in the string isn't recognizable, then `charEncodingUnknown` is returned.

**Comments** The encoding for the string is the maximum encoding of any character in that string. For example, if a two-character string contains a blank space and a ü, the appropriate encoding is `charEncodingISO8859_1`. The blank space's minimum encoding is ASCII. The minimum encoding for the ü is ISO 8859-1. The maximum of these two encodings is ISO 8859-1.

Use this function for informational purposes only. Your code should not assume that the character encoding returned by this function is the Palm OS system's character encoding. (Instead use `FtrGet` as shown in the [TxtCharXAttr\(\)](#) function description.)

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueStrEncoding`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

Palm OS only supports a single character encoding at a time. Because of this, the value returned from this function is always logically equal to or less than the encoding used on the current system. That is, you'll only receive a return value of `charEncodingISO8859_1` if you're running on a Latin-based system.

**See Also** [TxtCharEncoding\(\)](#), [TxtMaxEncoding\(\)](#)

## TxtTransliterate Function

**Purpose** Converts the specified number of bytes in a text buffer using the specified operation.

**Declared In** `TextMgr.h`

**Prototype**

```
Err TxtTransliterate (const Char* inSrcText,
                     UInt16 inSrcLength, Char* outDstText,
                     UInt16* ioDstLength, TranslitOpType inOp)
```

**Parameters**

- *inSrcText*  
Pointer to a text buffer.
- *inSrcLength*  
The length in bytes of *inSrcText*.
- ← *outDstText*  
The output buffer containing the converted characters.
- ↔ *ioDstLength*  
Upon entry, the maximum length of *outDstText*. Upon return, the actual length of *outDstText*.

→ *inOp*

A 16-bit unsigned value that specifies which transliteration operation is to be performed. See [TranslitOpType](#) for the possible values for this field.

Returns one of the following values:

`errNone`

Success

`txtErrUnknownTranslitOp`

`inOp`'s value is not recognized

`txtErrTranslitOverrun`

`inSrcText` and `outDstText` point to the same memory location and the operation has caused the function to overwrite unprocessed data in the input buffer.

`txtErrTranslitOverflow`

`outDstText` is not large enough to contain the converted string.

`txtErrTranslitUnderflow`

The end of the source buffer contains a partial character.

## Comments

`inSrcText` and `outDstText` may point to the same location if you want to perform the operation in place. However, you should be careful that the space required for `outDstText` is not larger than `inSrcText` so that you don't generate a `txtErrTranslitOverrun` error.

For example, suppose on a Shift JIS encoded system, you want to convert a series of single-byte Japanese Katakana symbols to double-byte Katakana symbols. You cannot perform this operation in place because it replaces a single-byte character with a multi-byte character. When the first converted character is written to the buffer, it overwrites the second input character. Thus, a text overrun has occurred.

You can ensure that you have enough space for the output by OR-ing your chosen operation with `translitOpPreprocess`. For example, to convert a string to uppercase letters, do the following:

---

```
outSize = buf2Len;  
error = TxtTransliterate(buf1, buflen, &buf2,  
                        &outSize,
```

## Text Manager

### *TxtWordBounds*

---

```
translitOpUpperCase|translitOpPreprocess);  
if (outSize > buf2len)  
    /* allocate more memory for buf2 */  
error = TxtTransliterate(buf1, buf1Len, &buf2,  
    &outSize, translitOpUpperCase);
```

---

You must make sure that the parameter `inSrcText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueTransliterate`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

In Palm OS 4.0, the `TxtTransliterate` function terminates when it finds a null byte in the source string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameter.

## TxtWordBounds Function

**Purpose** Find the boundaries of a word of text that contains the character starting at the specified offset.

**Declared In** `TextMgr.h`

**Prototype** `Boolean TxtWordBounds (const Char* inText,  
 UInt32 inLength, UInt32 inOffset,  
 UInt32* outStart, UInt32* outEnd)`

**Parameters**

- *inText*  
Pointer to a text buffer.
- *inLength*  
The length in bytes of the text pointed to by *inText*.
- *inOffset*  
A valid offset into the text buffer *inText*. This offset must point to the beginning of a character.
- ← *outStart*  
The starting offset of the text word.

$\leftarrow outEnd$

The ending offset of the text word.

**Returns** Returns `true` if a word is found. Returns `false` if the word doesn't exist or is punctuation or whitespace.

**Comments** Assuming the ASCII encoding, if the text buffer contains the string "Hi! How are you?" and you pass 5 as the offset, `TxtWordBounds` returns the start and end of the word containing the character at offset 5, which is the character "o". Thus, `outStart` and `outEnd` would point to the start and end of the word "How".

You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueWordBounds`. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

In Palm OS 4.0, the `TxtWordBounds` function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameter.

# Text Services Manager

---

This chapter provides information about the Text Services Manager API as declared in `TextServicesMgr.h`. The Text Services Manager provides the caller with an API for interacting with various text services, including front-end processors (FEPs), which are sometimes known as input methods. This chapter discusses the following topics:

- [Text Services Manager Data Structures](#)
- [Text Services Manager Functions](#)

## Text Services Manager Data Structures

### TsmFepModeType Typedef

|                  |                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>   | The <code>TsmFepModeType</code> type specifies the input modes used by the functions <a href="#">TsmGetFepMode()</a> and <a href="#">TsmSetFepMode()</a> . |
| <b>Prototype</b> | <code>typedef UInt16 TsmFepModeType;</code>                                                                                                                |
| <b>Comments</b>  | <code>TsmFepModeType</code> can be set to one of the defined modes listed in the following table.                                                          |

| Constant                       | Value | Description                                                                                           |
|--------------------------------|-------|-------------------------------------------------------------------------------------------------------|
| <code>tsmFepModeDefault</code> | 0     | The default input mode for the FEP. For example, with the Japanese FEP, the default mode is Hiragana. |

| Constant                      | Value | Description                                                                                                                                                     |
|-------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsmFepModeOff</code>    | 1     | Indicates that there is no active FEP input mode (the FEP is off).                                                                                              |
| <code>tsmFepModeCustom</code> | 128   | A custom FEP input mode. You can have more than one custom mode; the starting value is 128. Katagana is an example of a custom input mode for the Japanese FEP. |

## Text Services Manager Functions

### TsmGetFepMode Function

|                      |                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the current input mode for the active front-end processor (FEP).                                                                                                                                                                                                                                                |
| <b>Declared In</b>   | <code>TextServicesMgr.h</code>                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>     | <code>TsmFepModeType TsmGetFepMode (void *nullParam)</code>                                                                                                                                                                                                                                                            |
| <b>Parameters</b>    | <code>→ nullParam</code><br>An unused status pointer that must be set to NULL.                                                                                                                                                                                                                                         |
| <b>Returns</b>       | If there is an active FEP, returns the current mode for the active FEP. If there is no active FEP, returns <code>tsmFepModeOff</code> .                                                                                                                                                                                |
| <b>Comments</b>      | The most common use for this function is to save the current FEP mode. You could then call <a href="#">TsmSetFepMode()</a> to set the current mode to “off” and again to restore the saved mode once the application has finished using a special text field.                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. In Palm OS 3.5, the <code>nullParam</code> parameter takes a non-NULL value, allowing the caller to maintain its own status record. In Palm OS 4.0, this parameter is unused and must be set to NULL. Any other value generates a non-fatal alert. |
| <b>See Also</b>      | <a href="#">TsmSetFepMode()</a>                                                                                                                                                                                                                                                                                        |

## TsmSetFepMode Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the input mode for the active front-end processor (FEP) to be the mode defined by the parameter <code>inNewMode</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>TextServicesMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <code>TsmFepModeType TsmSetFepMode (void *nullParam,<br/>TsmFepModeType inNewMode)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>nullParam</i><br/>An unused status pointer that must be set to NULL.</p> <p>→ <i>inNewMode</i><br/>The new FEP input mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Returns</b>     | Returns the previous input mode. If there is no active FEP, returns <code>tsmFepModeOff</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | <p>The most common use for this function is to set the FEP mode to “off” while the application is using a special text field, and then to restore the previous mode. See <a href="#">TsmGetFepMode()</a> for more information on saving and restoring the FEP mode.</p> <p>One common reason for explicitly disabling the FEP in code is when a text field will only contain 7-bit ASCII (numeric fields automatically turn off the FEP). For example, if the application has a password field and the contents of that field will always be 7-bit ASCII, the application should turn off the FEP to help prevent the user from entering invalid characters into the field.</p> <p>Another common case occurs when the application has a numeric field, but cannot just rely on the numeric field attribute. For example, if you want the user to be able to enter the minus (“-”) sign, you cannot use a numeric field because the field code prevents the user from entering this character: its not a digit or a period. In this case, you should make it a regular field and have the application screen the characters. The application should disable the FEP when such a pseudo-numeric field is active.</p> |

## Text Services Manager

### *TsmSetFepMode*

---

---

**IMPORTANT:** A mode change is currently enqueued as a keyDown event so that the field and FEP can remain properly synchronized and so that the mode change doesn't affect any pending keyDown events. The mode change does not happen until the enqueued keyDown event is passed to `FrmHandleEvent`; if you call [TsmGetFepMode\(\)](#) immediately after calling [TsmSetFepMode\(\)](#), you won't see a mode change.

There are also some current limitations with changing the mode: there must be an active form; and if there is an active field in the form, it must not be a numeric field.

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. In Palm OS 3.5, the `nullParam` parameter takes a non-NULL value, allowing the caller to maintain its own status record. In Palm OS 4.0, this parameter is unused and must be set to NULL. Any other value generates a non-fatal alert.

**See Also** [TsmGetFepMode\(\)](#), [EvtEnqueueKey\(\)](#), [FrmHandleEvent\(\)](#)

# Time Manager

---

This chapter provides reference material for the time manager.

- [Time Manager Data Structures](#)
- [Time Manager Functions](#)

The header file `DateTime.h` declares the API that this chapter describes. For more information on the time manager, see the section “[Time](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Time Manager Data Structures

The time manager uses these structures to store information.

### DateFormatType Enum

**Purpose** The `DateFormatType` enum specifies the different display formats for date values.

**Prototype**

```
typedef enum {
    dfMDYWithSlashes,
    dfDMYWithSlashes,
    dfDMYWithDots,
    dfDMYWithDashes,
    dfYMDWithSlashes,
    dfYMDWithDots,
    dfYMDWithDashes,
    dfMDYLongWithComma,
    dfDMYLong,
    dfDMYLongWithDot,
    dfDMYLongNoDay,
    dfDMYLongWithComma,
    dfYMDLongWithDot,
    dfYMDLongWithSpace,
    dfMYMed,
```

```
    dfMYMedNoPost,  
    dfMDYWithDashes  
} DateFormatType;
```

#### **Value Descriptions**

|                  |                                                                               |
|------------------|-------------------------------------------------------------------------------|
| dfMDYWithSlashes | The month, day, and year numbers separated by slashes. For example, 12/31/95. |
|------------------|-------------------------------------------------------------------------------|

This is considered a short format.

|                  |                                                                               |
|------------------|-------------------------------------------------------------------------------|
| dfDMYWithSlashes | The day, month, and year numbers separated by slashes. For example, 31/12/95. |
|------------------|-------------------------------------------------------------------------------|

This is considered a short format.

|               |                                                                            |
|---------------|----------------------------------------------------------------------------|
| dfDMYWithDots | The day, month, and year numbers separated by dots. For example, 31.12.95. |
|---------------|----------------------------------------------------------------------------|

This is considered a short format.

|                 |                                                                              |
|-----------------|------------------------------------------------------------------------------|
| dfDMYWithDashes | The day, month, and year numbers separated by dashes. For example, 31-12-95. |
|-----------------|------------------------------------------------------------------------------|

This is considered a short format.

|                  |                                                                               |
|------------------|-------------------------------------------------------------------------------|
| dfYMDWithSlashes | The year, month, and day numbers separated by slashes. For example, 95/12/31. |
|------------------|-------------------------------------------------------------------------------|

This is considered a short format.

|                                 |                                                                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>dfYMDWithDots</code>      | <p>The year, month, and day numbers separated by dots. For example, 95.12.31.</p> <p>This is considered a short format.</p>       |
| <code>dfYMDWithDashes</code>    | <p>The year, month, and day numbers separated by dashes. For example, 95-12-31.</p> <p>This is considered a short format.</p>     |
| <code>dfMDYLongWithComma</code> | <p>The month, day, and year in long format, with a comma. For example, Dec 31, 1995.</p> <p>This is considered a long format.</p> |
| <code>dfDMYLong</code>          | <p>The month, day, and year in long format. For example, 31 Dec 1995.</p> <p>This is considered a long format.</p>                |
| <code>dfDMYLongWithDot</code>   | <p>The month, day, and year in long format, with a dot. For example, 31. Dec 1995.</p> <p>This is considered a long format.</p>   |
| <code>dfDMYLongNoDay</code>     | <p>The month and year in long format. For example, Dec 1995.</p> <p>This is considered a long format.</p>                         |

## Time Manager

### *DateFormatType*

---

|                                 |                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dfDMYLongWithComma</code> | The day, month, and year in long format, with a comma. For example, 31 Dec, 1995.<br><br>This is considered a long format.                    |
| <code>dfYMDLongWithDot</code>   | The year, month, and day in long format with dot separators. For example, 1995.12.31.<br><br>This is considered a long format.                |
| <code>dfYMDLongWithSpace</code> | The year, month, and day in long format with space separators. For example, 1995 Dec 31.<br><br>This is considered a long format.             |
| <code>dfMYMed</code>            | The month in long format with the two-digit year, preceded by an apostrophe. For example, Dec '95.<br><br>This is considered a medium format. |
| <code>dfMYMedNoPost</code>      | The month in long format with the two-digit year. For example, Dec 95.<br><br>This is considered a medium format.                             |
| <code>dfMDYWithDashes</code>    | The month, day, and year numbers separated by dashes. For example, 12-31-95.<br><br>This is considered a short format.                        |

**Compatibility** The `dfMDYWithDashes` constant is defined in Palm OS® 4.0 and higher.

## **DateTimeType Struct**

**Purpose** The DateTimeType structure represents a date and time value.

**Prototype**

```
typedef struct{
    Int16    second;
    Int16    minute;
    Int16    hour;
    Int16    day;
    Int16    month;
    Int16    year;
    Int16    weekDay;
} DateTimeType
typedef DateTimeType *DateTimePtr;
```

#### Field Descriptions

|         |                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------|
| second  | The number of seconds. This is a value between 0 and 59.                                             |
| minute  | The number of minutes. This is a value between 0 and 59.                                             |
| hour    | The number of hours. This is a value between 0 and 23.                                               |
| day     | The day number. This is a value between 1 and 31.                                                    |
| month   | The month number. This is a value between 1 and 12.                                                  |
| year    | The year number.                                                                                     |
| weekDay | The day number. This represents the number of days since Sunday and is thus a value between 0 and 6. |

#### DateType Struct

**Purpose** The DateType structure represents a date value.

**Prototype**

```
typedef struct{
    UInt16 year    :7;
    UInt16 month   :4;
    UInt16 day     :5;
} DateType;

typedef DateType *DatePtr;
```

#### Field Descriptions

|       |                                                           |
|-------|-----------------------------------------------------------|
| year  | The number of years since 1904.                           |
|       | Note that this is the format used on Macintosh computers. |
| month | The month number. This is a value between 1 and 12.       |
| day   | The day number. This is a value between 1 and 31.         |

## DaylightSavingsTypes Enum

**Purpose** The DaylightSavingsTypes enum specifies the different forms of daylight savings times that you can specify for date and time values.

Note that the table uses “DST” to represent daylight savings time.

**Prototype**

```
typedef enum {  
    dsNone,  
    dsUSA,  
    dsAustralia,  
    dsWesternEuropean,  
    dsMiddleEuropean,  
    dsEasternEuropean,  
    dsGreatBritain,  
    dsRumania,  
    dsTurkey,  
    dsAustraliaShifted  
} DaylightSavingsTypes;
```

### Value Descriptions

|                    |                                     |
|--------------------|-------------------------------------|
| dsNone             | No DST (daylight savings time)      |
| dsUSA              | U.S.A. DST                          |
| dsAustralia        | Australian DST                      |
| dsWesternEuropean  | Western European DST                |
| dsMiddleEuropean   | Middle European DST                 |
| dsEasternEuropean  | Eastern European DST                |
| dsGreatBritain     | Great Britain and Eire DST          |
| dsRumania          | Rumanian DST                        |
| dsTurkey           | Turkish DST                         |
| dsAustraliaShifted | Australian DST, with the 1986 shift |

**Compatibility** If [4.0 New Feature Set](#) is present, this data type is obsolete. In versions 4.0 and higher, Palm OS represents daylight savings time as an integer value that gives the number of minutes to add to the current time for daylight savings time.

## DayOfMonthType Enum

**Purpose** The `DayOfMonth` enum specifies the different day-of-the-week numeric values that are returned by the [DayOfMonth\(\)](#) function. These values are used to represent repeating appointments that occur on specific days of the month; for example, the first Friday or the third Tuesday of each month.

**Prototype**

```
typedef enum {  
    dom1stSun, dom1stMon, dom1stTue, dom1stWen,  
    dom1stThu, dom1stFri, dom1stSat,  
    dom2ndSun, dom2ndMon, dom2ndTue, dom2ndWen,  
    dom2ndThu, dom2ndFri, dom2ndSat,  
    dom3rdSun, dom3rdMon, dom3rdTue, dom3rdWen,  
    dom3rdThu, dom3rdFri, dom3rdSat,  
    dom4thSun, dom4thMon, dom4thTue, dom4thWen,  
    dom4thThu, dom4thFri, dom4thSat,  
    domLastSun, domLastMon, domLastTue,  
    domLastWen, domLastThu, domLastFri,  
    domLastSat  
} DayOfWeekType;
```

### Value Descriptions

|                        |                                    |
|------------------------|------------------------------------|
| <code>dom1stSun</code> | The first Sunday of the month.     |
| <code>dom1stMon</code> | The first Monday of the month.     |
| <code>dom1stTue</code> | The first Tuesday of the month.    |
| <code>dom1stWen</code> | The first Wednesday of the month.  |
| <code>dom1stThu</code> | The first Thursday of the month.   |
| <code>dom1stFri</code> | The first Friday of the month.     |
| <code>dom1stSat</code> | The first Saturday of the month.   |
| <code>dom2ndSun</code> | The second Sunday of the month.    |
| <code>dom2ndMon</code> | The second Monday of the month.    |
| <code>dom2ndTue</code> | The second Tuesday of the month.   |
| <code>dom2ndWen</code> | The second Wednesday of the month. |

|            |                                    |
|------------|------------------------------------|
| dom2ndThu  | The second Thursday of the month.  |
| dom2ndFri  | The second Friday of the month.    |
| dom2ndSat  | The second Saturday of the month.  |
| dom3rdSun  | The third Sunday of the month.     |
| dom3rdMon  | The third Monday of the month.     |
| dom3rdTue  | The third Tuesday of the month.    |
| dom3rdWen  | The third Wednesday of the month.  |
| dom3rdThu  | The third Thursday of the month.   |
| dom3rdFri  | The third Friday of the month.     |
| dom3rdSat  | The third Saturday of the month.   |
| dom4thSun  | The fourth Sunday of the month.    |
| dom4thMon  | The fourth Monday of the month.    |
| dom4thTue  | The fourth Tuesday of the month.   |
| dom4thWen  | The fourth Wednesday of the month. |
| dom4thThu  | The fourth Thursday of the month.  |
| dom4thFri  | The fourth Friday of the month.    |
| dom4thSat  | The fourth Saturday of the month.  |
| domLastSun | The last Sunday of the month.      |
| domLastMon | The last Monday of the month.      |
| domLastTue | The last Tuesday of the month.     |
| domLastWen | The last Wednesday of the month.   |
| domLastThu | The last Thursday of the month.    |
| domLastFri | The last Friday of the month.      |
| domLastSat | The last Saturday of the month.    |

**Compatibility** On Palm OS versions earlier than 4.0, this type was named *DayOfWeekType*.

## TimeFormatType Enum

**Purpose** The TimeFormatType enum specifies the different display formats for time values.

**Prototype**

```
typedef enum
{
    tfColon,
    tfColonAMPM,
    tfColon24h,
    tfDot,
    tfDotAMPM,
    tfDot24h,
    tfHoursAMPM,
    tfHours24h,
    tfComma24h,
} TimeFormatType;
typedef TimeFormatType *TimeFormatPtr;
```

### Value Descriptions

|             |                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------|
| tfColon     | The hour and minutes separated by a colon character. For example, 1:00.                               |
| tfColonAMPM | The hour and minutes separated by a colon and followed by an AM/PM indication. For example, 1:00 pm.  |
| tfColon24h  | The 24-hour time with the hour and minutes separated by a colon character. For example, 13:00.        |
| tfDot       | The hour and minutes separated by a dot character. For example, 1.00.                                 |
| tfDotAMPM   | The hour and minutes separated by a period and followed by an AM/PM indication. For example, 1.00 pm. |
| tfDot24h    | The 24-hour time with the hour and minutes separated by a dot character. For example, 13.00.          |
| tfHoursAMPM | The hour value followed by an AM/PM indication. For example, 1 pm.                                    |

|                         |                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------|
| <code>tfHours24h</code> | The 24-hour value, followed by an AM/PM indication. For example, 13.                           |
| <code>tfComma24h</code> | The 24-hour time with the hour and minutes separated by a comma character. For example, 13,00. |

## TimeType Struct

**Purpose** The `TimeType` structure represents a time value.

**Prototype**

```
typedef struct {
    UInt8    hours;
    UInt8    minutes;
} TimeType;
typedef TimeType *TimePtr;
```

### Field Descriptions

|                      |                                                        |
|----------------------|--------------------------------------------------------|
| <code>hours</code>   | The number of hours. This is a value between 0 and 23. |
| <code>minutes</code> | The number of minutes. This is value between 0 and 59. |

## Time Manager Constants

The following table shows the constants that represent the maximum lengths of strings returned by the date and time formatting routines [DateToAscii\(\)](#), [DateToDOWDMFormat\(\)](#), and [TimeToAscii\(\)](#).

| Constant                       | Value | Description                                                                                         |
|--------------------------------|-------|-----------------------------------------------------------------------------------------------------|
| <code>dateStringLength</code>  | 9     | Maximum length of the string returned by <code>DateToAscii</code> for short date formats.           |
| <code>longDateStrLength</code> | 15    | Maximum length of the string returned by <code>DateToAscii</code> for medium and long date formats. |
| <code>timeStringLength</code>  | 9     | Maximum length of the string returned by <code>TimeToAscii</code> .                                 |

## Time Manager

### *Time Manager Functions*

---

| Constant             | Value | Description                                                                                       |
|----------------------|-------|---------------------------------------------------------------------------------------------------|
| dowDateStringLength  | 19    | Maximum length of the string returned by DateToDOWDMFormat for short date formats.                |
| dowLongDateStrLength | 25    | Maximum length of the string returned by DateToDOWDMFormat for both medium and long date formats. |

---

## Time Manager Functions

### DateAdjust Function

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a new date +/- the days adjustment.                                                                                                                                                              |
| <b>Declared In</b> | DateTime.h                                                                                                                                                                                              |
| <b>Prototype</b>   | void DateAdjust (DateType *dateP,<br>Int32 adjustment)                                                                                                                                                  |
| <b>Parameters</b>  | $\leftrightarrow$ <i>dateP</i><br>A pointer to a <a href="#">DateType</a> structure with the date to be adjusted.<br>$\rightarrow$ <i>adjustment</i><br>The number of days by which to adjust the date. |
| <b>Returns</b>     | Returns nothing. Upon return, dateP contains the adjusted date.                                                                                                                                         |
| <b>Comments</b>    | This function advances the date and manages month and year wrapping conditions.                                                                                                                         |
| <b>See Also</b>    | <a href="#">TimAdjust()</a>                                                                                                                                                                             |

## DateDaysToDate Function

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a date specified as the number of days since January 1, 1904 to a <a href="#">DateType</a> structure.                                                                         |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                                                |
| <b>Prototype</b>   | <code>void DateDaysToDate (UInt32 days,<br/>                        DateType *dateP)</code>                                                                                            |
| <b>Parameters</b>  | <p>→ <i>days</i><br/>The number of days since 1/1/1904.</p> <p>↔ <i>dateP</i><br/>A pointer to a <a href="#">DateType</a> structure that is updated with the computed date values.</p> |
| <b>Returns</b>     | Returns nothing. Upon return, the date information is returned in the structure referenced by the <code>date</code> parameter.                                                         |
| <b>See Also</b>    | <a href="#">DateSecondsToDate ()</a> , <a href="#">DateToDays ()</a>                                                                                                                   |

## DateSecondsToDate Function

|                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a date specified as the number of seconds since January 1, 1904 to a <a href="#">DateType</a> structure.                                                                            |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                                                      |
| <b>Prototype</b>   | <code>void DateSecondsToDate (UInt32 seconds,<br/>                        DateType *dateP)</code>                                                                                            |
| <b>Parameters</b>  | <p>→ <i>seconds</i><br/>The number of seconds since 1/1/1904.</p> <p>← <i>dateP</i><br/>A pointer to a <a href="#">DateType</a> structure that is updated with the computed date values.</p> |
| <b>Returns</b>     | Returns nothing. The structure referenced by the <code>date</code> parameter is updated with the date information.                                                                           |
| <b>See Also</b>    | <a href="#">DateDaysToDate ()</a> , <a href="#">DateToDays ()</a>                                                                                                                            |

## **DateTemplateToAscii Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert the specified date values into a string that is formatted according to a formatting template specification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | <pre>UInt16 DateTemplateToAscii (const Char *templateP,<br/>    UInt8 months, UInt8 days, UInt16 years,<br/>    Char *stringP, Int16 stringLen)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>templateP</i><br/>A pointer to the template string used to format the date.<br/>See the Comments section below for details on how to specify date formatting in this template string.</p> <p>→ <i>months</i><br/>The month number, which must be a value between 1 and 12.</p> <p>→ <i>days</i><br/>The day number, which must be a value between 1 and 31.</p> <p>→ <i>years</i><br/>The four-digit year number. For example, 1995.</p> <p>← <i>stringP</i><br/>A pointer to a string that is updated with the result.<br/>If <i>stringP</i> is NULL, this function does not write an output string; however, it does return the length required for the output string.<br/>If <i>stringP</i> is not NULL, this function writes the formatted string to <i>stringP</i>, writing up to <i>stringSize</i> bytes into <i>stringP</i>.</p> <p>→ <i>stringLen</i><br/>The size of the <i>stringP</i> buffer.</p> |
| <b>Returns</b>     | <p>The length of the formatted string, without the terminating null byte.</p> <p>The <code>DateTemplateToAscii</code> returns the required length of the formatted string even if the <i>stringP</i> parameter is NULL; this allows you to determine the buffer size at runtime.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Comments</b>    | This function is intended as a replacement for the <a href="#">DateToAscii()</a> and <a href="#">DateToDOWDMFormat()</a> functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

This function uses the formatting template referenced by `templateP` to create a formatted string from the date values that you pass in.

You specify a series of formatting substrings in `templateP`. Each substring has the form:

---

```
^<valueType><formatModifier>
```

---

Each substring has three components:

- The `^` character begins a substring.
- The `<valueType>` component is a single-digit value that specifies the value type.
- The `<formatModifier>` component is a single-letter value that specifies how you want that value formatted.

The following is an example of a template specification with three substrings:

```
^0z ^2l ^4r
```

[Table 52.1](#) shows the values you can specify for the `<valueType>` component. Note that the formatted result depends on the `<modifier>` value.

**Table 52.1 Template value types for the `DateTemplateToAscii` function**

| Value | Value type   | Formatted examples |
|-------|--------------|--------------------|
| 0     | Day number   | 1, 01, 23, 31      |
| 1     | Day name     | Tue, Tuesday       |
| 2     | Month name   | May, Aug, August   |
| 3     | Month number | 4, 04, 11          |
| 4     | Year number  | 97, 1997           |

[Table 52.2](#) shows the values you can specify for the `<modifier>` component of each template substring.

**Table 52.2 Template modifier types for the  
DateTemplateToAscii function**

| Modifier | Description                                        |
|----------|----------------------------------------------------|
| s        | Formats the value in short form                    |
| r        | Formats the value in regular form                  |
| l        | Formats the value in long form                     |
| z        | Adds a leading zero to the formatted numeric value |

Finally, [Table 52.3](#) shows examples of each value type formatted with each modifier type.

**Table 52.3 Examples of formatted values**

| Value type          | Raw value | s<br>(Short<br>format) | r<br>(Regular<br>format) | l<br>(Long<br>format) | z<br>(Zero<br>format) |
|---------------------|-----------|------------------------|--------------------------|-----------------------|-----------------------|
| 0<br>(Day number)   | 2         | 2                      | 2                        | 2                     | 02                    |
| 1<br>(Day name)     | 2         | T                      | Tue                      | Tuesday               | n/a                   |
| 2<br>(Month name)   | 11        | N                      | Nov                      | November              | n/a                   |
| 3<br>(Month number) | 11        | 11                     | 11                       | 11                    | 11                    |
| 4<br>(Year number)  | 2000      | 00                     | 2000                     | 2000                  | n/a                   |

For example, calling `DateTemplateToAscii` as follows:

---

```
DateTemplateToAscii("^0z ^2l ^4r", 2, 7,  
2000, myStr, 20)
```

---

Produces the following formatted string:

07 February 2000

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `DateGlueTemplateToAscii`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [DateToAscii\(\)](#), [DateToDOWDMFormat\(\)](#)

## DateToAscii Function

**Purpose** Convert the passed date to a string using the format specified by the `dateFormat` parameter.

**Declared In** `DateTime.h`

**Prototype**

```
void DateToAscii (UInt8 months, UInt8 days,
                  UInt16 years, DateFormatType dateFormat,
                  Char *pString)
```

**Parameters**

- *months*  
The month number, which must be a value between 1 and 12.
- *days*  
The day number, which must be a value between 1 and 31.
- *years*  
The four-digit year number. For example, 1995.
- *dateFormat*  
Any [DateFormatType](#) format.
- ← *pString*  
A pointer to string that is updated with the result.  
This string must be of length `dateStringLength` for short formats or `longDateStrLength` for medium or long formats. Note that these lengths do include the terminating null byte. For more information about required string lengths, see [Time Manager Constants](#).

**Returns** Returns nothing. The string reference by `pString` is updated with the formatted string.

**Comments** If you are using a debug ROM, the string buffer is filled with either `dateStringLength` or `longStrLength` debugging bytes, depending on the value of the `dateFormat` parameter.

It is important to allocate enough space for your string buffer. Finding buffer overflow errors can be difficult when using a debug ROM. One common situation is when you pass a buffer that is too small from a form, for an element such as a label or title. Then, the buffer overflow can clobber objects that follow the form in memory. When a form element's location information is corrupted, it disappears from the display.

Note that you can use the [DateTemplateToAscii\(\)](#) function instead of this function if the 3.5 feature set is present. You can call the [DateTemplateToAscii\(\)](#) function with a NULL string buffer to predetermine the required size for your buffer.

[DateTemplateToAscii\(\)](#)

## DateToDays Function

**Purpose** Convert the [DateType](#) structure to the number of days elapsed from January 1, 1904.

**Declared In** `DateTime.h`

**Prototype** `UInt32 DateToDays (DateType date)`

**Parameters**  $\rightarrow$  *date*  
A [DateType](#) structure.

**Returns** Returns the number of days elapsed from January 1, 1904 to the specified date.

## DateToDOWDMFormat Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a date to a formatted string using the format specified by the <code>dateFormat</code> parameter. The resultant string includes the name of the day of the week.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | <pre>void DateToDOWDMFormat (UInt8 months, UInt8 days,                         UInt16 years, DateFormatType dateFormat,                         Char *pString)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>months</i><br/>The month number, which must be a value between 1 and 12.</p> <p>→ <i>days</i><br/>The day number, which must be a value between 1 and 31.</p> <p>→ <i>years</i><br/>The four-digit year number. For example, 1995.</p> <p>→ <i>dateFormat</i><br/>Any <a href="#">DateFormatType</a> format.</p> <p>← <i>pString</i><br/>A pointer to a string that is updated with the result. The string must be of length <code>dowDateStringLength</code> for short formats or <code>dowLongDateStrLength</code> for medium or long date formats. See <a href="#">Time Manager Constants</a> for string buffer lengths.</p>                                                                             |
| <b>Returns</b>     | Returns nothing. The string referenced by <code>pString</code> is updated with the formatted string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>The values of some of the <a href="#">Time Manager Constants</a> that specify the required string buffer lengths do change from time to time. You should always use the constants or verify the required lengths by checking the <code>datetime.h</code> file.</p> <p>It is important to allocate enough space for your string buffer. Finding buffer overflow errors can be difficult when using a debug ROM. One common situation is when you pass a buffer that is too small from a form, for an element such as a label or title. Then, the buffer overflow can clobber objects that follow the form in memory. When a form element's location information is corrupted, it disappears from the display.</p> |

Note that you can use the [DateTemplateToAscii\(\)](#) function instead of this function if the 3.5 feature set is present. You can call the [DateTemplateToAscii\(\)](#) function with a NULL string buffer to predetermine the required size for your buffer.

**Compatibility** On Palm OS 3.1 Japanese ROMs, this function contains a bug that prevented it from properly displaying 4-byte long day names. To prevent this bug from affecting your application, use `DateGlueToDOWDMFormat` in the `PalmOSGlue` library instead of calling this function directly. For more information, see [Chapter 75](#), “[PalmOSGlue Library](#).”

**See Also** [DateToAscii\(\)](#), [DateTemplateToAscii\(\)](#)

## DayOfMonth Function

**Purpose** Return a value that represents the day of a month on which the specified date occurs. The value represents a quantity such as “First Monday” or “Third Friday” as is used for repeating appointments in the Datebook.

**Declared In** `DateTime.h`

**Prototype** `Int16 DayOfMonth (Int16 month, Int16 day,  
Int16 year)`

**Parameters**

- *month*  
The month number, which must be a value between 1 and 12.
- *day*  
The day number, which must be a value between 1 and 31.
- *year*  
The four-digit year number. For example, 1995.

**Returns** Returns a value that represents day of the month. This value is one of the [DayOfMonthType](#) values.

**Comments** The returns value can be used to specify on which day of the month an appointment repeats.

## DayOfWeek Function

- Purpose** Return the day of the week value for a specified date.
- Declared In** `DateTime.h`
- Prototype** `Int16 DayOfWeek (Int16 month, Int16 day, Int16 year)`
- Parameters**
- *month*  
The month number, which must be a value between 1 and 12.
  - *day*  
The day number, which must be a value between 1 and 31.
  - *year*  
The four-digit year number. For example, 1995.
- Returns** Returns one of the following values for the day of the week of the specified date, as shown in the following table:

| Day name  | Returned day value |
|-----------|--------------------|
| Sunday    | 0                  |
| Monday    | 1                  |
| Tuesday   | 2                  |
| Wednesday | 3                  |
| Thursday  | 4                  |
| Friday    | 5                  |
| Saturday  | 6                  |

## **DaysInMonth Function**

|                    |                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of days in the month.                                                                                                                     |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                     |
| <b>Prototype</b>   | <code>Int16 DaysInMonth (Int16 month, Int16 year)</code>                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>month</i><br/>The month number, which must be a value between 1 and 12.</p> <p>→ <i>year</i><br/>The four-digit year number. For example, 1995.</p> |
| <b>Returns</b>     | Returns the number of days in the month for the specified year.                                                                                             |

## **TimAdjust Function**

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a new date, with the time adjusted by the specified number of seconds.                                                                                      |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                            |
| <b>Prototype</b>   | <code>void TimAdjust (DateTimeType *dateTimeP,<br/>Int32 adjustment)</code>                                                                                        |
| <b>Parameters</b>  | <p>↔ <i>dateTimeP</i><br/>A pointer to a <a href="#">DateType</a> structure.</p> <p>→ <i>adjustment</i><br/>The number of seconds by which to adjust the time.</p> |
| <b>Returns</b>     | Returns nothing. The structure referenced by <code>dateTimeP</code> is modified to contain the updated date and time.                                              |
| <b>Comments</b>    | This function advances the time by the specified number of seconds and takes care of any wraparound conditions.                                                    |
| <b>See Also</b>    | <a href="#">DateAdjust()</a>                                                                                                                                       |

## **TimDateTimeToSeconds Function**

- Purpose** Return the number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the specified date and time.
- Declared In** `DateTime.h`
- Prototype** `UInt32 TimDateTimeToSeconds  
(const DateTimeType *dateTimeP)`
- Parameters**  $\rightarrow$  `dateTimeP`  
A pointer to a [DateTimeType](#) structure.
- Returns** The number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the date referenced by `dateTimeP`.
- See Also** [TimSecondsToDateTime\(\)](#)

## **TimGetSeconds Function**

- Purpose** Return the current date and time of the device in seconds since 12:00 A.M. on January 1, 1904.
- Declared In** `TimeMgr.h`
- Prototype** `UInt32 TimGetSeconds (void)`
- Parameters** `None.`
- Returns** The number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the current date and time on the device.
- See Also** [TimSetSeconds\(\)](#)

## **TimGetTicks Function**

- Purpose** Return the tick count since the last reset. The tick count does not advance while the device is in sleep mode.
- Declared In** `TimeMgr.h`
- Prototype** `UInt32 TimGetTicks (void)`
- Parameters** `None.`
- Returns** Returns the tick count.

## Time Manager

### *TimSecondsToDateTime*

---

**Comments** You can call the [SysTicksPerSecond\(\)](#) routine to determine the number of ticks per second.

**See Also** [SysTicksPerSecond\(\)](#)

## TimSecondsToDateTime Function

**Purpose** Converts a date specified as the number of seconds since January 1, 1904 to a [DateTimeType](#) structure.

**Declared In** `DateTime.h`

**Prototype** `void TimSecondsToDateTime (UInt32 seconds,  
DateTimeType *dateTimeP)`

**Parameters**  $\rightarrow$  *seconds*  
A date specified as the number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the date  
 $\leftarrow$  *dateTimeP*  
A pointer to a [DateTimeType](#) structure that is updated with the date and time values.

**Returns** Returns nothing. The structure referenced by `dateTimeP` is updated with the date and time computed for the number of seconds since 12:00 A.M. on January 1, 1904.

**See Also** [TimDateTimeToSeconds\(\)](#)

## TimSetSeconds Function

**Purpose** Set the clock of the device to the date and time passed as the number of seconds since 12:00 A.M. on January 1, 1904.

**Declared In** `TimeMgr.h`

**Prototype** `void TimSetSeconds (UInt32 seconds)`

**Parameters**  $\rightarrow$  *seconds*  
The number of seconds since 12:00 A.M. on January 1, 1904.

**Returns** Returns nothing.

- Comments** If the [Notification Feature Set](#) is present, this function broadcasts the `sysNotifyTimeChangeEvent` to all interested parties. See [Chapter 39, “Notification Manager,”](#) for more information.
- See Also** [TimGetSeconds\(\)](#)

## TimeToAscii Function

- Purpose** Convert the time to a string that is formatted according to the specified `timeFormat`.
- Declared In** `DateTime.h`
- Prototype** `void TimeToAscii (UInt8 hours, UInt8 minutes, TimeFormatType timeFormat, Char *pString)`
- Parameters**
- *hours*  
The number of hours. This must be a value between 0 and 23.
  - *minutes*  
The number of minutes. This must be a value between 0 and 59.
  - *timeFormat*  
The time format for the resultant string. This must be one of the [TimeFormatType](#) values.
  - ← *pString*  
A pointer to a string that is updated with the resultant string. This string must be of length `timeStringLength`.  
See [Time Manager Constants](#) for information on string buffer lengths.
- Returns** Returns nothing. The string referenced by `pString` is updated with the formatted string.
- Comments** If you are using a debug ROM in Palm OS 3.5, the string buffer is filled with `timeStringLength` debugging bytes.

It is important to allocate enough space for your string buffer. Finding buffer overflow errors can be difficult when using a debug ROM. One common situation is when you pass a buffer that is too small from a form, for an element such as a label or title. Then, the buffer overflow can clobber objects that follow the form in memory.

When a form element's location information is corrupted, it disappears from the display.

**See Also**    [DateToAscii\(\)](#)

## TimeZoneToAscii Function

**Purpose**        Convert a time zone to a string.

**Declared In**   `DateTime.h`

**Prototype**    `void TimeZoneToAscii (Int16 timeZone,  
                          const LmLocaleType *localeP, Char *string)`

**Parameters**    $\rightarrow$  *timeZone*

A pointer to the time zone, given as minutes east of Greenwich Mean Time (GMT).

$\rightarrow$  *localeP*

A pointer to a locale (see [LmLocaleType](#)) that identifies the time zone country. You can use the constant `lmAnyLanguage` as the value for the language field of the structure pointed to by this parameter.

$\leftarrow$  *string*

A pointer to a string in which to return the result. This string must be of length `timeZoneStringLength`.

**Returns**       Returns nothing.

**Comments**     This function returns a descriptive string for the specified time zone. This string identifies the time zone first by its country, such as "USA (Mountain)" or "Canada (Eastern)." If the function cannot find a time zone that matches the specified GMT offset and country, it returns a string containing the time zone as a numeric offset from the GMT (for example, "GMT+9:00").

**Compatibility**   Implemented only if [4.0 New Feature Set](#) is present.

## TimTimeZoneToUTC Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a date and time from a given time zone to Universal Coordinated Time (UTC). UTC is also known as Greenwich Mean Time (GMT).                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | <code>DateTime.h</code>                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <code>UInt32 TimTimeZoneToUTC (UInt32 seconds,<br/>                          Int16 timeZone,<br/>                          Int16 daylightSavingAdjustment)</code>                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>seconds</i><br/>The number of seconds since 12:00 A.M. on January 1, 1904.</p> <p>→ <i>timeZone</i><br/>The time zone, given as the number of minutes east of UTC. For time zones west of UTC but before the international dateline, this is a negative number.</p> <p>→ <i>daylightSavingAdjustment</i><br/>The number of minutes to add to the current time for daylight savings time in this time zone.</p> |
| <b>Returns</b>     | Returns the same time as <i>seconds</i> but in the Universal Coordinated Time. The value is still given as the number of seconds since 12:00 A.M. on January 1, 1904.                                                                                                                                                                                                                                                  |
| <b>Comments</b>    | <p>The returned value is not necessarily the time in Greenwich because Greenwich may be observing daylight saving time.</p> <p>You can use this function to convert the local time to UTC. The time zone and the daylight savings adjustment are system preferences that can be retrieved using <a href="#">PrefGetPreference()</a>. For example, the following code converts the current local time to UTC:</p>       |

---

```
Int16 timeZone =  
    PrefGetPreference(prefTimeZone);  
Int16 daylightSavingAdjustment =  
    PrefGetPreference(  
        prefDaylightSavingAdjustment);  
UInt32 utcTime =  
    TimTimeZoneToUTC(TimGetSeconds(), timeZone,  
        daylightSavingAdjustment);
```

---

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">TimUTCToTimeZone()</a>                                  |

## TimUTCToTimeZone Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Converts a date and time from Universal Coordinated Time (UTC) to the specified time zone. UTC is also known as Greenwich Mean Time (GMT).                                                                                                                                                                                                                                                                                |
| <b>Declared In</b>   | <code>DateTime.h</code>                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>UInt32 TimUTCToTimeZone (UInt32 seconds,<br/>                          Int16 timeZone,<br/>                          Int16 daylightSavingAdjustment)</code>                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | <p>→ <i>seconds</i><br/>The number of seconds since 12:00 A.M. on January 1, 1904 in UTC.</p> <p>→ <i>timeZone</i><br/>The time zone, given as the number of minutes east of UTC. For time zones west of UTC before the international dateline, this is a negative number.</p> <p>→ <i>daylightSavingAdjustment</i><br/>The number of minutes to add to the current time for daylight savings time in this time zone.</p> |
| <b>Returns</b>       | Returns the same time as <i>seconds</i> but in the specified time zone. The value is still given as the number of seconds since 12:00 A.M. on January 1, 1904.                                                                                                                                                                                                                                                            |
| <b>Comments</b>      | The <i>seconds</i> value is not necessarily the time in Greenwich because Greenwich may be observing daylight saving time.                                                                                                                                                                                                                                                                                                |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                       |
| <b>See Also</b>      | <a href="#">TimTimeZoneToUTC()</a>                                                                                                                                                                                                                                                                                                                                                                                        |

# Virtual File System Manager

---

The Virtual File System (VFS) Manager is a layer of software that manages all installed file system libraries. It provides a unified API to application developers while allowing them to seamlessly access many different types of file systems —such as VFAT, HFS, and NFS—on many different types of media, including Compact Flash, Memory Stick, and SmartMedia. This chapter provides reference material for the VFS Manager API as follows:

- [VFS Manager Data Structures](#)
- [VFS Manager Constants](#)
- [VFS Manager Functions](#)
- [Application-Defined Functions](#)

The header file `VFSMgr.h` declares the VFS Manager API. For more information on the VFS Manager, see [Chapter 7, “Expansion,”](#) in *Palm OS Programmer’s Companion*, vol. I.

Note that the VFS Manager is an optional system extension; the functions described in this chapter are implemented only if the [VFS Manager Feature Set](#) is present.

## VFS Manager Data Structures

### FileInfoType Struct

**Purpose** The `FileInfoType` structure contains information about a specified file or directory. This information is returned as a parameter to [VFSDirEntryEnumerate\(\)](#). The structure is defined as follows:

**Prototype** `typedef struct FileInfoTag {`

## Virtual File System Manager

### *FileRef*

---

```
    UInt32 attributes;
    Char *nameP;
    UInt16 nameBufLen;
} FileInfoType, *FileInfoPtr;
```

#### Field Descriptions

|            |                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| attributes | Characteristics of the file or directory. See <a href="#">File and Directory Attributes</a> for the bits that make up this field.                    |
| nameP      | Pointer to the buffer that receives the full name of the file or directory. Initialize this parameter to NULL if you don't want to receive the name. |
| nameBufLen | Size of the nameP buffer, in bytes.                                                                                                                  |

#### FileRef Typedef

**Purpose** The FileRef type is used to encode references to files and directories.

**Prototype** `typedef UInt32 FileRef;`

#### VFSAnyMountParamType Struct

**Purpose** The VFSAnyMountParamType structure is a base structure for [VFSSlotMountParamType](#), [VFSPoseMountParamType](#), and other similar structures that may be defined in the future. Use one or the other according to how you set the mountClass parameter.

**Prototype**

```
typedef struct VFSAnyMountParamTag {
    UInt16 volRefNum;
    UInt16 reserved;
    UInt32 mountClass;
} VFSAnyMountParamType;

typedef VFSAnyMountParamType *VFSAnyMountParamPtr;
```

### Field Descriptions

|            |                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| volRefNum  | The volume reference number. This is initially obtained when you successfully mount a volume. It can then be used to format a volume with <a href="#">VFSVolumeFormat()</a> or unmount a volume with <a href="#">VFSVolumeUnmount</a> . |
| reserved   | Reserved for future use.                                                                                                                                                                                                                |
| mountClass | Defines the type of mount to use with the specified volume. See <a href="#">Volume Mount Classes</a> for a list of mount types.                                                                                                         |

## VFSSlotMountParamType Struct

**Purpose** The VFSSlotMountParamType structure is used when you are mounting a card located in an Expansion Manager slot. The vfsMountParam->mountClass field must be set to VFSMountClass\_SlotDriver.

**Prototype**

```
typedef struct VFSSlotMountParamTag {  
    VFSAnyMountParamType vfsMountParam;  
    UInt16 slotLibRefNum;  
    UInt16 slotRefNum;  
} VFSSlotMountParamType;
```

### Field Descriptions

|               |                                                                                                                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vfsMountParam | See the description of <a href="#">VFSAnyMountParamType</a> for an explanation of the fields in this structure. Set vfsMountParam->mountClass to VFSMountClass_SlotDriver to mount an Expansion Manager slot. |
| slotLibRefNum | Reference number for the slot driver library allocated to the given slot number. Obtain this field by calling <a href="#">ExpSlotLibFind()</a> .                                                              |
| slotRefNum    | Number of the slot to be mounted.                                                                                                                                                                             |

## VFSPoSEMountParamType Struct

**Purpose** The VFSPoSEMountParamType structure is used when you are mounting a volume through the Palm OS® Emulator. The `vfsMountParam->mountClass` must be set to `VFSMountClass_POSE`. Note that ordinary applications and file systems shouldn't use VFSPoSEMountParamType.

**Prototype**

```
typedef struct VFSPoSEMountParamTag {
    VFSAnyMountParamType vfsMountParam;
    UInt8 poseSlotNum;
} VFSPoSEMountParamType
```

### Field Descriptions

|                            |                                                                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vfsMountParam</code> | See the description of <a href="#">VFSAnyMountParamType</a> for an explanation of the fields in this structure. Set <code>vfsMountParam-&gt;mountClass</code> to <code>VFSMountClass_POSE</code> to mount a virtual slot. |
| <code>poseSlotNum</code>   | Number of the virtual slot number to be mounted by the Palm OS Emulator.                                                                                                                                                  |

## VolumeInfoType Struct

**Purpose** The VolumeInfoType structure defines information that is returned to [VFSVolumeInfo\(\)](#) and used throughout the VFS functions.

**Prototype**

```
typedef struct VolumeInfoTag {
    UInt32 attributes;
    UInt32 fsType;
    UInt32 fsCreator;
    UInt32 mountClass;
    UInt16 slotLibRefNum;
    UInt16 slotRefNum;
    UInt32 mediaType;
    UInt32 reserved;
} VolumeInfoType, *VolumeInfoPtr;
```

### Field Descriptions

|               |                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| attributes    | Characteristics of the volume. See <a href="#">Volume Attributes</a> for the bits that make up this field.                                                                                                                    |
| fsType        | File system type for this volume. See <a href="#">Defined File Systems</a> for a list of the supported file systems.                                                                                                          |
| fsCreator     | Creator ID of this volume's file system driver. This information is used with <a href="#">VFSCustomControl()</a> .                                                                                                            |
| mountClass    | Mount class that mounted this volume. The supported mount classes are listed under <a href="#">Volume Mount Classes</a> .                                                                                                     |
| slotLibRefNum | Reference to the slot driver library with which the volume is mounted. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> .                                                               |
| slotRefNum    | Slot number where the card containing the volume is loaded. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> .                                                                          |
| mediaType     | Type of card media. See <a href="#">Defined Media Types</a> in the <a href="#">Expansion Manager</a> chapter for the list of values. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> . |
| reserved      | Reserved for future use.                                                                                                                                                                                                      |

## VFS Manager Constants

### Defined File Systems

The following file systems are currently defined by the VFS Manager. These values are used with [VFSVolumeInfo\(\)](#) in the `VolumeInfoType.fsType` parameter.

| Constant                               | Value               | Description                                       |
|----------------------------------------|---------------------|---------------------------------------------------|
| <code>vfsFilesystemType_AFS</code>     | <code>'afsu'</code> | Unix Andrew file system                           |
| <code>vfsFilesystemType_EXT2</code>    | <code>'ext2'</code> | Linux file system                                 |
| <code>vfsFilesystemType_FAT</code>     | <code>'fats'</code> | FAT12 and FAT16, which only handles 8.3 filenames |
| <code>vfsFilesystemType_FFS</code>     | <code>'ffsb'</code> | Unix Berkeley block based file system             |
| <code>vfsFilesystemType_HFS</code>     | <code>'hfss'</code> | Macintosh standard hierarchical file system       |
| <code>vfsFilesystemType_HFSPlus</code> | <code>'hfse'</code> | Macintosh extended hierarchical file system       |
| <code>vfsFilesystemType_HPFS</code>    | <code>'hpfs'</code> | OS2 High Performance file system                  |
| <code>vfsFilesystemType_MFS</code>     | <code>'mfso'</code> | Macintosh original file system                    |
| <code>vfsFilesystemType_NFS</code>     | <code>'nfsu'</code> | Unix Networked file system                        |
| <code>vfsFilesystemType_Novell</code>  | <code>'novl'</code> | Novell file system                                |

| Constant                            | Value               | Description                                       |
|-------------------------------------|---------------------|---------------------------------------------------|
| <code>vfsFileSystemType_NTFS</code> | <code>'ntfs'</code> | Windows NT file system                            |
| <code>vfsFileSystemType_VFAT</code> | <code>'vfat'</code> | FAT12 and FAT16 extended to handle long filenames |

## Open Mode Constants

This section describes constants that are used for the `openMode` parameter to the [VFSFileOpen\(\)](#) function. These constants specify the mode in which a file or directory is opened.

| Constant                      | Value                                                   | Description                                                                                                                                                            |
|-------------------------------|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vfsModeExclusive</code> | <code>0x0001U</code>                                    | Open and lock the file or directory. This mode excludes anyone else from using the file or directory until it is closed.                                               |
| <code>vfsModeRead</code>      | <code>0x0002U</code>                                    | Open for read access.                                                                                                                                                  |
| <code>vfsModeWrite</code>     | <code>0x0004U  </code><br><code>vfsModeExclusive</code> | Open for write access.                                                                                                                                                 |
| <code>vfsModeReadWrite</code> | <code>vfsModeWrite  </code><br><code>vfsModeRead</code> | Open for read/write access.                                                                                                                                            |
| <code>vfsModeCreate</code>    | <code>0x0008U</code>                                    | Create the file if it doesn't already exist. This open mode is implemented in the VFS layer, rather than in the file system library.                                   |
| <code>vfsModeTruncate</code>  | <code>0x0010U</code>                                    | Truncate the file to zero (0) bytes after opening, removing all existing data. This open mode is implemented in the VFS layer, rather than in the file system library. |

## Virtual File System Manager

### *File and Directory Attributes*

---

| Constant                         | Value                                            | Description                                                                                                                |
|----------------------------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>vfsModeVFSLayerOnly</code> | <code>vfsModeCreate  <br/>vfsModeTruncate</code> | Mask used to isolate those flags that are only used by the VFS layer. These flags are not passed to the file system layer. |
| <code>vfsModeLeaveOpen</code>    | <code>0x0020U</code>                             | Leave the file open even after the application exits.                                                                      |

---

### File and Directory Attributes

The constants in the following table define bits that can be used individually or in combination when setting or interpreting the file attributes for a given file or directory. See [VFSFileGetAttributes\(\)](#), [VFSFileSetAttributes\(\)](#), and the [FileInfoType](#) data structure for specific use.

| Constant                            | Value                     | Description                       |
|-------------------------------------|---------------------------|-----------------------------------|
| <code>vfsFileAttrReadOnly</code>    | <code>0x00000001UL</code> | Read-only file or directory       |
| <code>vfsFileAttrHidden</code>      | <code>0x00000002UL</code> | Hidden file or directory          |
| <code>vfsFileAttrSystem</code>      | <code>0x00000004UL</code> | System file or directory          |
| <code>vfsFileAttrVolumeLabel</code> | <code>0x00000008UL</code> | Volume label                      |
| <code>vfsFileAttrDirectory</code>   | <code>0x00000010UL</code> | Directory                         |
| <code>vfsFileAttrArchive</code>     | <code>0x00000020UL</code> | Archived file or directory        |
| <code>vfsFileAttrLink</code>        | <code>0x00000040UL</code> | Link to another file or directory |

---

### Volume Attributes

The constants in the following table define bits that can be used individually or in combination to make up the attributes field in the [VolumeInfoType](#) structure.

| Constant                            | Value                     | Description                                                           |
|-------------------------------------|---------------------------|-----------------------------------------------------------------------|
| <code>vfsVolumeAttrHidden</code>    | <code>0x00000004UL</code> | The volume should not be visible to the user.                         |
| <code>vfsVolumeAttrReadOnly</code>  | <code>0x00000002UL</code> | The volume is read only.                                              |
| <code>vfsVolumeAttrSlotBased</code> | <code>0x00000001UL</code> | Reserved. Check the mount class to determine how a volume is mounted. |

---

## Volume Mount Classes

The following constants define how a given volume is mounted. The `mountClass` field in the [VFSAnyMountParamType](#) and [VolumeInfoType](#) structures takes on one of these values.

| Constant                              | Value                           | Description                                                              |
|---------------------------------------|---------------------------------|--------------------------------------------------------------------------|
| <code>vfsMountClass_POSE</code>       | <code>'pose'</code>             | Mount the volume through the Palm OS Emulator. This is used for testing. |
| <code>vfsMountClass_Simulator</code>  | <code>sysFileTSimulator</code>  | Mount the volume through the simulator. This is used for testing.        |
| <code>vfsMountClass_SlotDriver</code> | <code>sysFileTSlotDriver</code> | Mount the volume with a slot driver shared library.                      |

---

## Error Codes

The VFS Manager defines the following error codes:

## Virtual File System Manager

### Error Codes

---

| Constant                                | Description                                                                                                |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>vfsErrBadData</code>              | The operation could not be completed because of invalid data.                                              |
| <code>vfsErrBadName</code>              | Invalid filename, path, or volume label.                                                                   |
| <code>vfsErrBufferOverflow</code>       | The supplied buffer is too small.                                                                          |
| <code>vfsErrDirectoryNotFound</code>    | Returned when the path leading up to the file does not exist.                                              |
| <code>vfsErrDirNotEmpty</code>          | The directory is not empty and therefore cannot be deleted.                                                |
| <code>vfsErrFileAlreadyExists</code>    | A file with this name exists already in this location.                                                     |
| <code>vfsErrFileBadRef</code>           | The file reference is invalid: it has been closed or was not obtained from <a href="#">VFSFileOpen()</a> . |
| <code>vfsErrFileEOF</code>              | The file pointer is at the end of the file.                                                                |
| <code>vfsErrFileGeneric</code>          | Generic file error.                                                                                        |
| <code>vfsErrFileNotFound</code>         | The file was not found at the specified location.                                                          |
| <code>vfsErrFilePermissionDenied</code> | The requested permissions could not be granted.                                                            |
| <code>vfsErrFileStillOpen</code>        | Returned from the underlying file system's delete function if the file is still open.                      |

| <b>Constant</b>                       | <b>Description</b>                                                                                 |
|---------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>vfsErrIsADirectory</code>       | This operation can only be performed on a regular file, not a directory.                           |
| <code>vfsErrNameShortened</code>      | A volume name or filename was automatically shortened to conform to the file system specification. |
| <code>vfsErrNoFileSystem</code>       | None of the installed file systems support this operation.                                         |
| <code>vfsErrNotADirectory</code>      | This operation can only be performed on a directory.                                               |
| <code>vfsErrVolumeBadRef</code>       | The volume reference number is invalid.                                                            |
| <code>vfsErrVolumeFull</code>         | There is insufficient space left on the volume.                                                    |
| <code>vfsErrVolumeStillMounted</code> | Returned from the underlying file system's format function if the volume is still mounted.         |

## VFS Manager Functions

### VFSCustomControl Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Make a custom API call to a particular file system, given its creator ID. You can use <a href="#">VFSVolumeInfo()</a> to determine the creator ID of the file system for a given volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Err VFSCustomControl (UInt32 fsCreator,<br/>                     UInt32 apiCreator, UInt16 apiSelector,<br/>                     void *valueP, UInt16 *valueLenP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>fsCreator</i><br/>Creator of the file system to call. A value of zero (0) tells the VFS Manager to check each registered file system, looking for one which supports the call.</p> <p>→ <i>apiCreator</i><br/>Registered creator ID.</p> <p>→ <i>apiSelector</i><br/>Custom operation to perform.</p> <p>↔ <i>valueP</i><br/>A pointer to a buffer containing data specific to the operation. On exit, depending on the function of the particular custom call and on the value of <i>valueLenP</i>, the contents of this buffer may have been updated.</p> <p>↔ <i>valueLenP</i><br/>On entry, points to the size of the <i>valueP</i> buffer. On exit, this value reflects the size of the data written to the <i>valueP</i> buffer. If <i>valueLenP</i> is NULL, <i>valueP</i> is passed to the file system but is not updated on exit.</p> |
| <b>Returns</b>     | Returns one of the following error codes:<br><br><i>errNone</i><br>No error.<br><br><i>expErrNotOpen</i><br>The file system library necessary for this call has not been installed or has not been opened.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

`expErrUnsupportedOperation`

The specified opcode and/or creator is unsupported or undefined.

`sysErrParamErr`

The `valueP` buffer is too small.

`vfsErrNoFileSystem`

VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The driver identifies the call and its API by a registered creator ID and a selector. This allows file system developers to extend the API by defining selectors for their creator IDs. It also allows file system developers to support selectors (and custom calls) defined by other file system developers.

This function must return `expErrUnsupportedOperation` for all unsupported or undefined opcodes and/or creators.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSDirCreate Function

**Purpose** Create a new directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSDirCreate(UInt16 volRefNum,  
const Char *dirNameP)`

**Parameters**  $\rightarrow$  `volRefNum`  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).

$\rightarrow$  `dirNameP`  
Pointer to the full path of the directory to be created.

**Returns** Returns one of the following error codes:

`errNone`

No error

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

## Virtual File System Manager

### *VFSDirEntryEnumerate*

---

`vfsErrBadName`

Some or all of the path, up to but not including the last component specified in the `dirNameP` parameter, does not exist.

`vfsErrFileAlreadyExists`

A file with this name already exists in this location.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Comments** All parts of the path except the last component must already exist. The `vfsFileAttrDirectory` attribute is set with this function.

[VFSDirCreate\(\)](#) does not open the directory. Any operations you want to perform on this directory require a reference, which is obtained through a call to [VFSFileOpen\(\)](#).

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSDirEntryEnumerate Function

**Purpose** Enumerate the entries in a given directory. Entries can include files, links, and other directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSDirEntryEnumerate (FileRef dirRef,  
                                UInt32 *dirEntryIteratorP, FileInfoType  
                                *infoP)`

**Parameters**  $\rightarrow$  `dirRef`  
Directory reference returned from [VFSFileOpen\(\)](#).

$\leftrightarrow$  `dirEntryIteratorP`  
Pointer to the index of the last entry enumerated. For the first iteration, initialize this parameter to the constant `vfsIteratorStart`. Upon return, this references the next entry in the directory. If `infoP` is the last entry, this parameter is set to `vfsIteratorStop`.

$\leftrightarrow$  *infoP*

Pointer to the [FileInfoType](#) data structure that contains information about the given directory entry. The *nameP* and *nameBufLen* fields in this structure must be initialized prior to calling `VFSDirEntryEnumerate`.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrEnumerationEmpty`

There are no directory entries left to enumerate.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`sysErrParamErr`

The *dirEntryIteratorP* is not valid.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsNotADirectory`

The specified file reference is valid, but does not point to a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The directory to be enumerated must first be opened with [VFSFileOpen\(\)](#) in order to obtain a file reference. In order to obtain information on all entries in a directory you must make repeated calls to `VFSDirEntryEnumerate` inside a loop. Boundaries on the iteration are the defined constants `vfsIteratorStart` and `vfsIteratorStop`. Before the first call to `VFSDirEntryEnumerate`, *dirEntryIteratorP* should be initialized to `vfsIteratorStart`. Each iteration then changes the value pointed to by *dirEntryIteratorP*. When information on the last entry in the directory is returned, *dirEntryIteratorP* is set to `vfsIteratorStop`.

## Virtual File System Manager

### *VFSDirEntryEnumerate*

---

---

**WARNING!** Creating, renaming, or deleting any file or directory invalidates the enumeration. After any such operation, the enumeration will need to be restarted.

---

**Example** The following code excerpt illustrates how to use *VFSDirEntryEnumerate*.

---

```
FileInfoType info;
FileRef dirRef;
UInt32 dirIterator;
Char *fileName = MemPtrNew(256); // should check for err

// open the directory first, to get the directory reference
// volRefNum must have already been defined
err = VFSFileOpen(volRefNum, "/", vfsModeRead, &dirRef);
if(err == errNone) {

    info.nameP = fileName; // point to local buffer
    info.nameBufLen = 256;
    dirIterator = vfsIteratorStart
    while (dirIterator != vfsIteratorStop) {
        // Get the next file
        err = VFSDirEntryEnumerate (dirRef, &dirIterator,
            &info);
        if (err == errNone) {
            // Do something with the directory entry information
            // Pull the attributes from info.attributes
            // The file name is in fileName
        } else {
            // handle error, possibly by breaking out of the
loop
        }
    } else {
        // handle directory open error here
    }
    MemPtrFree(fileName);
}
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## **VFSExportDatabaseToFile Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Save the specified database to a .pdb or .prc file on an external storage card.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Err VFSExportDatabaseToFile (UInt16 volRefNum,<br/>    const Char *pathNameP, UInt16 cardNo,<br/>    LocalID dbID)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Comments</b>    | <p>This utility function exports a database from main memory to a .pdb or .prc file on an external storage card. This function is the opposite of <a href="#">VFSImportDatabaseFromFile()</a>. It first creates the file specified in the <i>pathNameP</i> parameter with <a href="#">VFSFileCreate()</a>. After opening the file the Exchange Manager function <a href="#">ExgDBWrite()</a> is called with an internal callback function for exporting the file from the Data Manager. The Exchange Manager makes repeated calls to this callback function, which</p> |

## Virtual File System Manager

### *VFSExportDatabaseToFileCustom*

---

receives the data back in blocks. Once all the data has been exported, VFS Manager closes the file.

This function is used, for example, to copy applications from main memory to a storage card.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFileCustom\(\)](#), [VFSFileWrite\(\)](#), [VFSImportDatabaseFromFile\(\)](#)

## VFSExportDatabaseToFileCustom Function

**Purpose** Saves the specified database to a .pdb or .prc file on an external storage card. This function differs from [VFSExportDatabaseToFile\(\)](#) in that it allows you to track the progress of the export operation.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSExportDatabaseToFileCustom  
(UInt16 volRefNum, const Char *pathNameP,  
UInt16 cardNo, LocalID dbID,  
VFSExportProcPtr exportProcP, void *userDataP)`

**Parameters**

- *volRefNum*  
Volume on which the destination file should be created.
- *pathNameP*  
Pointer to the complete path and name of the destination file to be created.
- *cardNo*  
Card number on which the .pdb or .prc being exported resides.
- *dbID*  
ID of the database being exported.
- *exportProcP*  
User-defined callback function that tracks the progress of the export. This function should allow the user to cancel the export. Pass NULL if you don't have a progress callback function. See [VFSExportProcPtr\(\)](#) for the requirements of this function.

→ *userDataP*

Pointer to any data you want to pass to the callback function specified in `exportProcP`. This information is not used internally by the VFS Manager. Pass `NULL` if you don't have a progress callback function or if that function doesn't need any such data.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotEnoughPower`

There is insufficient battery power to perform the database export operation.

`vfsErrBadName`

The path name specified in `pathNameP` is not valid.

This function can also return any error code other than `errNone` produced by your callback function.

**Comments** This function is similar to [VFSExportDatabaseToFile\(\)](#) in that it exports a database from main memory to a `.pdb` or `.prc` file on an external storage card. It extends the functionality by allowing you to specify a callback function that tracks the progress of the export. It first creates the file specified in the `pathNameP` parameter with [VFSFileCreate\(\)](#). After opening the file, the Exchange Manager function [ExgDBWrite\(\)](#) is called with an internal callback function for exporting the file from the Data Manager. Exchange Manager makes repeated calls to this function, which receives the data back in blocks. The progress tracker, if one has been specified, is also called every time a new chunk of data is passed back. Once all the data has been exported, the VFS Manager closes the file.

This function is used, for example, to copy applications from main memory to a storage card.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile\(\)](#), [VFSFileWrite\(\)](#), [VFSImportDatabaseFromFileCustom\(\)](#)

## VFSFileClose Function

|                      |                                                                                                                                                                                                                                                                  |

## VFSFileCreate Function

|                    |                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create a file. This function cannot be used to create a directory; use <a href="#">VFSDirCreate()</a> instead.                                                                                                                                                                                                             |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | Err VFSFileCreate(UInt16 volRefNum,<br>const Char *pathNameP)                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | → <i>volRefNum</i><br>Reference number of the volume on which to create the file. This volume reference number is returned from <a href="#">VFSVolumeEnumerate()</a> .<br><br>→ <i>pathNameP</i><br>Pointer to the full path of the file to be created. All parts of the path, excluding the filename, must already exist. |
| <b>Returns</b>     | Returns one of the following error codes:<br><br>errNone<br>No error.                                                                                                                                                                                                                                                      |

expErrNotOpen

The file system library necessary for this call has not been installed or has not been opened.

vfsErrBadName

The pathNameP is invalid.

vfsErrFileAlreadyExists

A file with this name already exists in this location.

vfsErrNoFileSystem

The VFS Manager cannot find an appropriate file system to handle the request.

vfsErrVolumeBadRef

The volume has not been mounted.

vfsErrVolumeFull

There is not enough space left on the volume.

**Comments**

It is the responsibility of the file system library to ensure that all filenames are translated into a format that is compatible with the native format of the file system, such as the 8.3 convention for a FAT file system without long filename support. See [Naming Files](#) in the [Expansion](#) chapter of the *Palm OS Programmer's Companion*, vol. I for a description of how to construct a valid path.

This function does not open the file. Use [VFSFileOpen\(\)](#) to open the file.

This function should not be used to create a directory. To create a directory use [VFSDirCreate\(\)](#).

**Compatibility**

Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**

[VFSFileDelete\(\)](#)

| <b>Purpose</b>     | Load a record from an opened .pdb file on an external card into the storage heap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <pre>Err VFSFileDBGetRecord (FileRef ref,<br/>                        UInt16 recIndex, MemHandle *recHP,<br/>                        UInt8 *recAttrP, UInt32 *uniqueIDP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p>→ <i>ref</i><br/>The file reference returned from <a href="#">VFSFileOpen()</a>. Note that the open file must be a .pdb file.</p> <p>→ <i>recIndex</i><br/>The index of the record to load.</p> <p>← <i>recHP</i><br/>Pointer to the record data's handle in the storage heap. If NULL is returned in this parameter there is either no data in this field or an error occurred reading this data from the file. If the handle is not NULL, you must dispose of the allocated handle using <a href="#">MemHandleFree()</a>.</p> <p>← <i>recAttrP</i><br/>Pointer to the attributes of the record. The values returned are identical to the attributes returned from <a href="#">DmRecordInfo()</a>. See <a href="#">Record Attribute Constants</a> in the <a href="#">Data and Resource Manager</a> chapter for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve this information.</p> <p>← <i>uniqueIDP</i><br/>Pointer to the unique identifier for this record. Pass NULL for this parameter if you do not want to retrieve this information.</p> |
| <b>Returns</b>     | Returns one of the following error codes:<br><br><i>errNone</i><br>No error.<br><br><i>dmErrIndexOutOfRange</i><br>The <i>recIndex</i> is out of range.<br><br><i>dmErrNotRecordDB</i><br>The file referenced by <i>ref</i> is not a record database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`memErrNotEnoughSpace`

There is not enough space in memory for the requested record entry.

`sysErrParamErr`

A NULL value was passed in for the `recHP`, `recAttrP`, and `uniqueIDP` parameters.

`vfsErrBadData`

The local offsets (`localChunkID`) from the top of the `.pdb` to the start of the raw record data for this entry are out of order.

**Comments** This function is analogous to [DmGetRecord\(\)](#) but works with files on an external card rather than databases in main memory. This function allocates a handle of the appropriate size from the storage heap and returns it in the `recHP` parameter. The caller is responsible for freeing this memory, using [MemHandleFree\(\)](#), when it is no longer needed.

---

**NOTE:** This function is not efficient for multiple accesses and should be used sparingly.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileReadData\(\)](#)

## VFSFileDBGetResource Function

**Purpose** Load a resource into the storage heap from an opened `.prc` file.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileDBGetResource (FileRef ref,  
DmResType type, DmResID resID, MemHandle  
*resHP)`

**Parameters**  $\rightarrow$  *ref*  
The file reference returned from [VFSFileOpen\(\)](#). Note that the open file must be a `.prc` file.

$\rightarrow$  *type*  
The type of resource to load. See the [Data and Resource Manager](#) chapter for more information on resources.

## Virtual File System Manager

### *VFSFileDBGetResource*

---

→ *resID*

The ID of resource to load.

← *resHP*

Pointer to the resource data handle that was loaded into memory.

**Returns** Returns one of the following error codes:

*errNone*

No error.

*dmErrNotResourceDB*

The file referenced by *ref* is not a resource database.

*dmErrResourceNotFound*

The requested resource was not found.

*memErrNotEnoughSpace*

There is not enough space in memory for the requested resource entries.

*sysErrParamErr*

*resHP* is NULL.

**Comments** This function locates the specified resource in the open *.prc* file. See the *Palm OS File Format Specification* for more information on the layout of *.prc* files.

Once the resource is found, *VFSFileDBGetResource* allocates a handle of the appropriate size in the storage heap and reads it into memory. The handle to this memory location is returned through the *resHP* parameter. The caller is responsible for freeing this memory, using [MemHandleFree\(\)](#), when it is no longer needed.

---

**NOTE:** This function is not efficient for multiple accesses and should be used sparingly.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

| <b>Purpose</b>     | Get information about a database represented by an open .prc or .pdb file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <pre>Err VFSFileDBInfo (FileRef ref, Char *nameP,<br/>    UInt16 *attributesP, UInt16 *versionP,<br/>    UInt32 *crDateP, UInt32 *modDateP,<br/>    UInt32 *bckUpDateP, UInt32 *modNumP,<br/>    MemHandle *appInfoHP, MemHandle *sortInfoHP,<br/>    UInt32 *typeP, UInt32 *creatorP,<br/>    UInt16 *numRecordsP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <i>ref</i><br/>The file reference returned from <a href="#">VFSFileOpen()</a>. Note that the open file must be a .prc or .pdb file.</p> <p>← <i>nameP</i><br/>Pointer to a 32-byte character array in which the database name is returned. Pass NULL for this parameter if you do not want to retrieve the database name.</p> <p>← <i>attributesP</i><br/>Pointer to the database attributes stored in the file. The values returned are identical to the attributes returned from <a href="#">DmDatabaseInfo()</a>. See the <a href="#">Database Attribute Constants</a> section for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve the database's attributes.</p> <p>← <i>versionP</i><br/>Pointer to the application-specific version number of the database. The default version number is zero (0). Pass NULL for this parameter if you do not want to retrieve the version number.</p> <p>← <i>crDateP</i><br/>Pointer to the date the database was created, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass NULL for this parameter if you do not want to retrieve the creation date.</p> <p>← <i>modDateP</i><br/>Pointer to the date the database was last modified, expressed in seconds since midnight (00:00:00) January 1, 1904. A</p> |

## Virtual File System Manager

### VFSFileDBInfo

---

database's modification date is updated only if a change has been made to the database when it is opened with write access. Pass NULL for this parameter if you do not want to retrieve the database's modification date.

← *bckUpDateP*

Pointer to the date the database was last backed up, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass NULL for this parameter if you do not want to retrieve the database's backup date.

← *modNumP*

Pointer to the number of times the database was modified. This number is updated every time a record is added, modified, or deleted. Pass NULL for this parameter if you do not want to retrieve the modification count.

← *appInfoHP*

Pointer to the application info block handle. If NULL is returned in this parameter, either there is no data in this field or an error occurred reading this data from the file. If a value other than NULL is returned, you must dispose of the allocated handle using [MemHandleFree\(\)](#). If you do not want to retrieve the application info block, pass NULL for this parameter

← *sortInfoHP*

Pointer to the sort info block handle. If NULL is returned in this parameter, either there is no data in this field or an error occurred reading this data from the file. If a value other than NULL is returned, you must dispose of the allocated handle using [MemHandleFree\(\)](#). Pass NULL for this parameter if you do not want to retrieve the sort info block handle.

← *typeP*

Pointer to the type of database as it was created. This may be a user-defined database type or a database type defined by the Palm OS. Some of the more common database types returned here are:

| Type   | Description                                    |
|--------|------------------------------------------------|
| 'appl' | Standard Palm™ application (resource database) |
| 'libr' | Standard shared library                        |
| 'libf' | File system shared library                     |
| 'libs' | Slot driver shared library                     |
| 'data' | Standard Palm data file (record database)      |

Pass NULL for this parameter if you do not want to retrieve the database's type.

← *creatorP*

Pointer to the database's creator. Pass NULL for this parameter if you do not want to retrieve this information.

← *numRecordsP*

Pointer to the number of records in the database. Pass NULL for this parameter if you do not want to retrieve this information.

**Returns** Returns one of the following error codes:

`errNone`

No error

`memErrNotEnoughSpace`

There is not enough space in memory for the database header.

`vfsErrBadData`

The file referenced by the `ref` parameter is too small to contain a database header, or the database header is corrupted.

**Comments** This function is analogous to [DmDatabaseInfo\(\)](#), but it works with files on an external card rather than with databases in main memory. See the *Palm OS File Format Specification* for a description of the header block in `.prc` and `.pdb` files.

## Virtual File System Manager

### *VFSFileDelete*

---

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSFileGetAttributes\(\)](#), [VFSFileGetDate\(\)](#)

## VFSFileDelete Function

**Purpose**         Deletes a closed file or directory.

**Declared In**    `VfsMgr.h`

**Prototype**     `Err VFSFileDelete(UInt16 volRefNum,  
                      const Char *pathNameP)`

**Parameters**    `→ volRefNum`  
                  Volume reference number returned from  
                  [VFSVolumeEnumerate\(\)](#).  
  
                  `→ pathNameP`  
                  Pointer to the full path of the file or directory to be deleted.

**Returns**        Returns one of the following error codes:

`errNone`

    No error.

`expErrNotOpen`

    The file system library necessary for this call has not been  
    installed or has not been opened.

`vfsErrBadName`

    The path name specified in `pathNameP` is not valid.

`vfsErrDirNotEmpty`

    The directory being deleted is not empty.

`vfsErrFileStillOpen`

    The file is still open.

`vfsErrFileNotFound`

    The file could not be found.

`vfsErrFilePermissionDenied`

    The requested permissions could not be granted.

`vfsErrNoFileSystem`

    The VFS Manager cannot find an appropriate file system to  
    handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileEOF Function

**Purpose** Get end-of-file status for an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileEOF (FileRef fileRef)`

**Parameters**  $\rightarrow$  *fileRef*  
File reference returned from [VFSFileOpen\(\)](#).

**Returns** Returns one of the following error codes:

`errNone`

No error. File pointer is not at end of the file.

`vfsErrFileEOF`

The file pointer is at the end of file.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileGetAttributes Function

|                      |                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Obtain the attributes of an open file or directory.                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b>   | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                   |

## VFSFileGetDate Function

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Obtain the dates on an open file or directory.                                          |
| <b>Declared In</b> | VfsMgr.h                                                                                |
| <b>Prototype</b>   | Err VFSFileGetDate (FileRef fileRef,<br>UInt16 whichDate, UInt32 *dateP)                |
| <b>Parameters</b>  | <p>→ <i>fileRef</i><br/>File reference returned from <a href="#">VFSFileOpen()</a>.</p> |

→ *whichDate*

Specifies which date—creation, modification, or last access—you want. Supply one of the following values:

`vfsFileDateCreated`

`vfsFileDateModified`

`vfsFileDateAccessed`

Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, `VFSFileGetDate` returns `expErrUnsupportedOperation`.

← *dateP*

Pointer to the requested date. This field is expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`expErrUnsupportedOperation`

The specified date type is not supported by the underlying file system.

`vfsErrFileBadRef`

The specified file reference is invalid.

`sysErrParamErr`

The `whichDate` parameter is not one of the defined constants.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileDBInfo\(\)](#), [VFSFileGetAttributes\(\)](#),  
[VFSFileSetDate\(\)](#)

## VFSFileOpen Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Opens a file or directory and returns a reference for it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | <code>VfsMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>Err VFSFileOpen (UInt16 volRefNum,<br/>    const Char *pathNameP, UInt16 openMode,<br/>    FileRef *fileRefP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p>→ <code>volRefNum</code><br/>The volume reference number returned from <a href="#">VFSVolumeEnumerate()</a>.</p> <p>→ <code>pathNameP</code><br/>Pointer to the full path of the file or directory to be opened. This must be a valid path. It cannot be empty and can not contain null characters. The format of the pathname should match what the underlying file system supports. See “<a href="#">Naming Files</a>” in <a href="#">Chapter 7</a>, “<a href="#">Expansion</a>,” of the <i>Palm OS Programmer’s Companion</i>, vol. I for a description of how to construct a valid path.</p> <p>→ <code>openMode</code><br/>Mode to use when opening the file. See the <a href="#">Open Mode Constants</a> section for a list of accepted modes.</p> <p>← <code>fileRefP</code><br/>Pointer to the opened file or directory reference which is supplied to various other <code>VFSFile...</code> operations. This value is filled in on return.</p> |
| <b>Returns</b>     | Returns one of the following error codes:<br><br><code>errNone</code><br>No error.<br><br><code>expErrCardReadOnly</code><br>The open mode requested includes write access but the file is read-only.<br><br><code>expErrNotOpen</code><br>The file system library necessary for this call has not been installed or has not been opened.<br><br><code>vfsErrBadName</code><br>The <code>pathNameP</code> parameter is invalid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

`vfsErrFileNotFound`

The specified file or directory could not be found.

`vfsErrFilePermissionDenied`

The file cannot be opened in the requested open mode, or it has already been opened with `vfsModeExclusive`.

`vfsErrVolumeBadRef`

The specified volume has not been mounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileClose\(\)](#), [VFSDirEntryEnumerate\(\)](#)

## VFSFileRead Function

**Purpose** Read data from a file into the dynamic heap. This function only operates on files and cannot be used with directories; use [VFSDirEntryEnumerate\(\)](#) to explore the contents of a directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileRead (FileRef fileRef,  
                  UInt32 numBytes, void *bufP,  
                  UInt32 *numBytesReadP)`

**Parameters**  $\rightarrow$  *fileRef*  
File reference returned from [VFSFileOpen\(\)](#).

$\rightarrow$  *numBytes*  
Number of bytes to read.

$\leftarrow$  *bufP*  
Pointer to the destination chunk where the data is to be stored. This can be a pointer to any writable memory.

$\leftarrow$  *numBytesReadP*  
Pointer to an unsigned integer that reflects the number of bytes actually read. This value is set on return and does not need to be initialized. If no bytes are read the value is set to zero. Pass NULL for this parameter if you do not need to know how many bytes were read.

**Returns** Returns one of the following error codes:

`errNone`  
No error.

## Virtual File System Manager

### *VFSFileReadData*

---

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrFileEOF`

The end of the file has been reached.

`vfsErrFilePermissionDenied`

Read permission is not enabled for this file.

`vfsErrIsADirectory`

The specified file reference is for a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The file system does not use [DmWrite\(\)](#) and cannot be used to read data into the storage heap.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileReadData\(\)](#), [VFSFileWrite\(\)](#),  
[VFSImportDatabaseFromFile\(\)](#)

## VFSFileReadData Function

**Purpose** Read data from a file into a chunk of memory in the storage heap. This function only operates on files and cannot be used with directories; use [VFSDirEntryEnumerate\(\)](#) to explore the contents of a directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileReadData (FileRef fileRef,  
                          UInt32 numBytes, void *bufBaseP, UInt32  
                          offset, UInt32 *numBytesReadP)`

**Parameters**   
→ *fileRef*  
File reference returned in [VFSFileOpen\(\)](#).  
  
→ *numBytes*  
Number of bytes to read.

← *bufBaseP*

Pointer to the destination chunk in the storage heap where the data is to be stored. This pointer must be obtained through the appropriate call to the [Memory Manager](#) API.

→ *offset*

Offset, in bytes, within the *bufBaseP* chunk where the data is to be written.

← *numBytesReadP*

Pointer to an unsigned integer that reflects the number of bytes actually read. This value is set on return and does not need to be initialized. If no bytes are read, the value is set to zero. Pass NULL for this parameter if you do not need to know how many bytes were read.

**Returns** Returns one of the following error codes:

*errNone*

No error.

*expErrNotOpen*

The file system library necessary for this call has not been installed or has not been opened.

*vfsErrFileBadRef*

The specified file reference is invalid.

*vfsErrFileEOF*

The end of the file has been reached.

*vfsErrFilePermissionDenied*

Read permission is not enabled for this file.

*vfsErrIsADirectory*

The specified file reference is for a directory instead of a file. This is an invalid operation on a directory.

*vfsErrNoFileSystem*

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** When data is read from an external card with `VFSFileReadData`, it is copied into a chunk of memory in the storage heap. This chunk **must** be allocated by the application before the call to `VFSFileReadData()`. This function calls `DmWrite()` to put the data in the storage heap.

## Virtual File System Manager

### *VFSFileRename*

---

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSFileRead\(\)](#), [VFSFileWrite\(\)](#)

## VFSFileRename Function

**Purpose**         Rename a closed file or directory. This function cannot be used to move a file to another directory within the file system.

**Declared In**    `VfsMgr.h`

**Prototype**     `Err VFSFileRename (UInt16 volRefNum,  
                      const Char *pathNameP, const Char *newNameP)`

**Parameters**    `→ volRefNum`  
                  Volume reference number returned from [VFSVolumeEnumerate\(\)](#).  
  
                  `→ pathNameP`  
                  Pointer to the full path of the file or directory to be renamed.  
  
                  `→ newNameP`  
                  Pointer to the new filename. Note that this is the name of the file only and does not include the path to the file.

**Returns**        Returns one of the following error codes:

`errNone`

    No error.

`expErrNotOpen`

    The file system library necessary for this call has not been installed or has not been opened.

`vfsErrBadName`

    The name provided in either `pathNameP` or `newNameP` is invalid. This is also returned if the string pointed to by `newNameP` is a path, rather than a filename.

`vfsErrFileAlreadyExists`

    A file with the new name already exists in this location.

`vfsErrFileNotFound`

    The source file could not be found.

`vfsErrFilePermissionDenied`

    Write permission is not enabled for this file.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

`vfsErrVolumeFull`

There is not enough space left on the volume.

---

**Comments**    **WARNING!** This function invalidates directory enumeration. You cannot continue enumerating files after renaming one of them with this function. If you need to operate on additional files in the directory, you must first restart the enumeration.

---

**Example**    Below is an example of how to use `VFSFileRename`. Note that the renamed file remains in the `/PALM/Programs` directory; `VFSFileRename` can't be used to move files from one directory to another.

---

```
// volRefNum must have been previously defined; most likely,
// it was returned by VFSVolumeEnumerate

err = VFSFileRename(volRefNum, "/PALM/Programs/foo.prc",
    "bar.prc");
if (err != errNone) {
    // handle error...
}
```

---

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileResize Function

**Purpose**    Change the size of an open file. This function only operates on files and cannot be used with directories.

**Declared In**    `VfsMgr.h`

**Prototype**    `Err VFSFileResize (FileRef fileRef,`  
                  `UInt32 newSize)`

**Parameters**     $\rightarrow$  *fileRef*  
                  File reference returned from [VFSFileOpen\(\)](#).

## Virtual File System Manager

### *VFSFileSeek*

---

→ *newSize*

The desired new size of the file. This can be larger or smaller than the current file size.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Comments** The location of the file pointer is undefined after a call to this function.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileSize\(\)](#)

## VFSFileSeek Function

**Purpose** Set the position within an open file from which to read or write. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileSeek (FileRef fileRef,  
FileOrigin origin, Int32 offset)`

**Parameters** → *fileRef*  
File reference returned from [VFSFileOpen\(\)](#).

→ *origin*

Origin to use when calculating the new position. The *offset* parameter indicates the desired new position relative to this origin, which can be one of the following:

`vfsOriginBeginning`

The beginning of the file.

`vfsOriginCurrent`

The current position within the file.

`vfsOriginEnd`

The end of the file. Only negative offsets are allowed when origin is set to `vfsOriginEnd`.

→ *offset*

Offset, either positive or negative, from the origin to which the current position should be set. A value of zero (0) positions you at the specified origin.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrFileEOF`

The file pointer is at the end of file.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`sysErrParamErr`

The specified origin is not one of the defined constants.

**Comments** During a call to this function, if the resulting position would be beyond the end of the file, it sets the position to the end of the file.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileSize\(\)](#), [VFSFileTell\(\)](#)

## VFSFileSetAttributes Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Change the attributes of an open file or directory.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Declared In</b>   | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>     | Err VFSFileSetAttributes (FileRef fileRef,<br>UInt32 attributes)                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>    | <p>→ <i>fileRef</i><br/>File reference returned from <a href="#">VFSFileOpen()</a>.</p> <p>→ <i>attributes</i><br/>Attributes to associate with the file or directory. See <a href="#">File and Directory Attributes</a> for a list of values you can use when setting this parameter:</p>                                                                                                                                              |
| <b>Returns</b>       | Returns one of the following error codes:<br><br>errNone<br>No error.<br><br>expErrNotOpen<br>The file system library necessary for this call has not been installed or has not been opened.<br><br>sysErrParamErr<br>One of the parameters is invalid.<br><br>vfsErrFileBadRef<br>The specified file reference is invalid.<br><br>vfsErrNoFileSystem<br>The VFS Manager cannot find an appropriate file system to handle the request.  |
| <b>Comments</b>      | <b>NOTE:</b> You cannot use this function to set the <code>vfsFileAttrDirectory</code> or <code>vfsFileAttrVolumeLabel</code> attributes. The <code>vfsFileAttrDirectory</code> is set when you call <a href="#">VFSDirCreate()</a> . The <code>vfsFileAttrVolumeLabel</code> is set when you call <a href="#">VFSVolumeSetLabel()</a> . This function may fail when setting other attributes, depending on the underlying file system. |
| <b>Compatibility</b> | Implemented only if the <a href="#">VFS Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                             |
| <b>See Also</b>      | <a href="#">VFSFileGetAttributes()</a> , <a href="#">VFSFileSetDate()</a>                                                                                                                                                                                                                                                                                                                                                               |

## VFSFileSetDate Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Changes the dates on an open file or directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | VfsMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | Err VFSFileSetDate (FileRef fileRef,<br>UInt16 whichDate, UInt32 date)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p>→ <i>fileRef</i><br/>File reference returned in <a href="#">VFSFileOpen()</a>.</p> <p>→ <i>whichDate</i><br/>Specifies which date—creation, modification, or last access—to modify. Supply one of the following values:</p> <p>vfsFileDateCreated<br/>vfsFileDateModified<br/>vfsFileDateAccessed</p> <p>Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.</p> <p>→ <i>date</i><br/>The new date. This field should be expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.</p> |
| <b>Returns</b>     | Returns one of the following error codes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                    | errNone<br>No error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Virtual File System Manager

### *VFSFileSize*

---

`vfsErrFilePermissionDenied`

Write permission is not enabled for this file.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileGetDate\(\)](#), [VFSFileSetAttributes\(\)](#)

## VFSFileSize Function

**Purpose** Obtain the size of an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileSize (FileRef fileRef,  
UInt32 *fileSizeP)`

**Parameters**  $\rightarrow$  `fileRef`  
File reference returned from [VFSFileOpen\(\)](#).  
 $\leftarrow$  `fileSizeP`  
Pointer to the size of the open file.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileResize\(\)](#), [VFSFileTell\(\)](#), [VFSVolumeSize\(\)](#)

## VFSFileTell Function

**Purpose** Get the current position of the file pointer within an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileTell (FileRef fileRef,  
                  UInt32 *filePosP)`

**Parameters**  $\rightarrow$  *fileRef*  
File reference returned from [VFSFileOpen\(\)](#).  
 $\leftarrow$  *filePosP*  
Pointer to the current file position.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileSeek\(\)](#), [VFSFileSize\(\)](#)

## VFSFileWrite Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile\(\)](#),  
[VFSExportDatabaseToFileCustom\(\)](#), [VFSFileRead\(\)](#),  
[VFSFileReadData\(\)](#)

## VFSGetDefaultDirectory Function

**Purpose** Determine the default location on the given volume for files of a particular type.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSGetDefaultDirectory (UInt16 volRefNum,  
const Char *fileTypeStr, Char *pathStr,  
UInt16 *bufLenP)`

**Parameters**

- `volRefNum`  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).
- `fileTypeStr`  
Pointer to the requested file type, as a null-terminated string. The file type may either be a MIME media type/subtype pair, such as "image/jpeg", "text/plain", or "audio/basic"; or a file extension, such as ".jpeg."
- ← `pathStr`  
Pointer to the buffer which receives the default directory path for the requested file type.
- ↔ `bufLenP`  
Pointer to the size of the path. Set this to the size of `pathStr` buffer on input. Reflects the number of bytes copied to `pathStr` on output.

**Returns** Returns one of the following error codes:

- `errNone`  
No error.
- `vfsErrBadName`  
There is no default directory registered for the requested file type.

---

`vfsErrBufferOverflow`

A match was found, but the `pathStr` buffer is too small to hold the resulting path string. A partial path is returned in `pathStr`.

`vfsErrFileNotFound`

No match was found for the specified volume. The error could have occurred with either the media type specified for this volume or the file type requested.

**Comments** This function returns the complete path to the default directory registered for the specified file type. A default directory can be registered for each type of media supported. The directory should be registered under media and file type. Note that this directory is typically a “root” directory for the file type; any subdirectories under this root directory should also be searched for files of the appropriate type.

This function can be used by an image viewer application, for example, to find the directory containing images without having to know what type of media the volume was on. This could be “/DCIM”, “/images”, or something else depending on the type of media.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSDirEntryEnumerate\(\)](#),  
[VFSRegisterDefaultDirectory\(\)](#),  
[VFSUnregisterDefaultDirectory\(\)](#)

## VFSImportDatabaseFromFile Function

**Purpose** Creates a database from a .pdb or .prc file on an external storage card.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSImportDatabaseFromFile (UInt16 volRefNum,  
const Char *pathNameP, UInt16 *cardNoP,  
LocalID *dbIDP)`

**Parameters**  $\rightarrow$  `volRefNum`  
Volume on which the source file resides.

→ *pathNameP*

Pointer to the full path and name of the source file.

← *cardNoP*

Pointer to a variable that receives the card number of the newly-created database. If the database already resides in the storage heap, the card number of the existing database is returned along with the error `dmErrAlreadyExists`.

← *dbIDP*

Pointer to a variable that receives the database ID of the new database. If the database already resides in the storage heap, the database ID of the existing database is returned along with the error `dmErrAlreadyExists`.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`dmErrAlreadyExists`

The `.prc` or `.pdb` file already exists in the storage heap. In this case the `cardNoP` and `dbIDP` are set to point to the existing file.

`expErrNotEnoughPower`

There is insufficient battery power to complete the requested operation.

`vfsErrBadName`

The path name specified in `pathNameP` is not valid.

**Comments** This utility function imports a `.pdb` or `.prc` file resident on an external storage card into a new database in the storage heap. It first calls [`VFSFileOpen\(\)`](#) to open the file specified in `pathNameP`. Assuming that a corresponding `.prc` or `.pdb` does not already exist in the storage heap, [`VFSImportDatabaseFromFile\(\)`](#) calls the Exchange Manager function [`ExgDBRead\(\)`](#) with an internal callback function for importing a file to the Data Manager. The Exchange Manager makes repeated calls to this function, which passes the data back in blocks. Once the file has been successfully imported, the owner (the imported file, if it's an executable, or the associated application if it is not) is sent a [`sysAppLaunchCmdSyncNotify`](#) launch code to make it aware of the new database.

## Virtual File System Manager

### *VFSImportDatabaseFromFileCustom*

---

This function only imports the specified .pdb or .prc file; it does not import bundled databases or overlays. If there are bundled databases and/or overlays associated with the .pdb or .prc file you are importing, you will need to write additional code to explicitly handle them.

This function doesn't provide any progress indication to the user. If you need to provide feedback to the user as the file import progresses, use [VFSImportDatabaseFromFileCustom\(\)](#) instead.

This function is used, for example, to copy applications from a storage card to main memory.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile\(\)](#), [VFSFileRead\(\)](#)

## VFSImportDatabaseFromFileCustom Function

**Purpose** Create a database from the specified .pdb or .prc file on an external storage card. This function differs from [VFSImportDatabaseFromFile\(\)](#) in that it allows you to track the progress of the import operation.

**Declared In** `VfsMgr.h`

**Prototype**

```
Err VFSImportDatabaseFromFileCustom
    (UInt16 volRefNum, const Char *pathNameP,
     UInt16 *cardNoP, LocalID *dbIDP,
     VFSImportProcPtr importProcP, void *userDataP)
```

**Parameters**

- *volRefNum*  
Volume on which the source file resides.
- *pathNameP*  
Pointer to the full path and name of the source file.
- ← *cardNoP*  
Pointer to the variable that receives the card number of the newly-created database. If the database already resides in the storage heap, the card number of the existing database is returned along with the error `dmErrAlreadyExists`.

← *dbIDP*

Pointer to the variable that receives the database ID of the new database. If the database already resides in the storage heap, the database ID of the existing database is returned along with the error `dmErrAlreadyExists`.

→ *importProcP*

User-defined callback function that tracks the progress of the import. This function should allow the user to cancel the import. Pass `NULL` if you don't have a progress callback function. See [VFSImportProcPtr\(\)](#) for the requirements of this function.

→ *userDataP*

Pointer to any data you want to pass to the callback function specified in `importProcP`. This information is not used internally by the VFS Manager. Pass `NULL` if you don't have a progress callback function, or if that function doesn't need any such data.

**Returns** Returns one of the following error codes:

`errNone`

No error

`vfsErrBadName`

The path name specified in `pathNameP` is not valid.

`expErrNotEnoughPower`

The power required to import a database is not available.

`dmErrAlreadyExists`

The `.prc` or `.pdb` file already exists in main memory. In this case the `cardNoP` and `dbIDP` are set to point to the existing file.

**Comments** This function is similar to [VFSImportDatabaseFromFile\(\)](#) in that it imports a `.pdb` or `.prc` file on an external storage card into a new database on the storage heap. It extends the functionality by allowing you to specify a callback function that tracks the progress of the export. It first calls [VFSFileOpen\(\)](#) to open the file specified in `pathNameP`. If a corresponding `.prc` or `.pdb` does not already exist in main memory, it calls the Exchange Manager function [ExgDBRead\(\)](#) with an internal callback function for importing the file from the Data Manager. The Exchange Manager makes repeated calls to this function, which receives the data back in blocks. The

## Virtual File System Manager

### *VFSInstallFSLib*

---

progress tracker, if one has been specified, is also called every time a new chunk of data is passed back. Once the file has been successfully imported, the owner (the imported file, if it's an executable, or the associated application if it is not) is sent a [sysAppLaunchCmdSyncNotify](#) launch code to make it aware of the new database.

Like `VFSImportDatabaseFromFile`, this function only imports the specified `.pdb` or `.prc` file; it does not import bundled databases or overlays.

This function is used, for example, to copy applications from a storage card to main memory.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileRead\(\)](#), [VFSExportDatabaseToFileCustom\(\)](#)

## VFSInstallFSLib Function

- Purpose** Install a file system library so that the VFS Manager can use it.
- Declared In** `VfsMgr.h`
- Prototype** `Err VFSInstallFSLib (UInt32 creator, UInt16 *fsLibRefNumP)`
- Parameters**
- *creator*  
Creator ID of the database containing the file system library to be installed.
  - ← *fsLibRefNumP*  
Pointer to the reference number for the newly installed file system library. Supply NULL for this parameter if you don't need the library reference number.
- Returns** If the file system library was loaded and installed without error, `errNone` is returned. Any error generated by the underlying file system while opening the file system library or determining its type will be returned from `VFSInstallFSLib`. Other errors that can be generated during the file system library installation process include:
- `expErrIncompatibleAPIVer`  
The file system library has an incompatible API version.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`memErrNotEnoughSpace`, `memErrChunkNotLocked`, or  
`memErrChunkLocked`

A memory problem occurred while inserting the library reference into the list of installed libraries.

`sysErrLibNotFound`, `sysErrNoFreeRAM`,  
`sysErrNoFreeLibSlots` (or some other error  
returned from the library's install entry point)

An error occurred while loading the library.

**Comments** This function calls [SysLibLoad\(\)](#) to load the file system library into the library table. Once loaded the appropriate file system is asked to open the library. At boot time `VFSInstallFSLib` is called internally by the Expansion Manager to load all installed file system libraries and initialize them for use.

`VFSInstallFSLib` is not normally called by applications.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSRemoveFSLib\(\)](#)

## VFSRegisterDefaultDirectory Function

**Purpose** Registers a specific directory as the default location for files of a given type on a particular kind of external storage card. This function is generally called by a slot driver for files and media types that are supported by that slot driver.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSRegisterDefaultDirectory`  
`(const Char *fileTypeStr, UInt32 mediaType,`  
`const Char *pathStr)`

**Parameters**  $\rightarrow$  `fileTypeStr`

Pointer to the file type to register. This is a null-terminated string that can either be a MIME media type/subtype pair, such as "image/jpeg", "text/plain", or "audio/basic"; or a file extension, such as ".jpeg".

## Virtual File System Manager

### *VFSRegisterDefaultDirectory*

---

→ *mediaType*

Type of card media for which the default directory is being associated. See [Defined Media Types](#) in the [Expansion Manager](#) chapter for the list of accepted values.

→ *pathStr*

Pointer to the default directory path to be associated with the specified file type. This string must be null-terminated, and must be the full path to the directory.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`sysErrParamErr`

Either the `fileTypeStr` parameter is NULL or the `pathStr` parameter is NULL.

`vfsErrFileAlreadyExists`

A default directory has already been registered for this file type on the specified card media type.

**Comments** This function first verifies that a default directory has not already been registered for the specified combination of file type and media type, and returns `vfsErrFileAlreadyExists` if one has been registered. To change an existing entry in the registry, you must first remove the existing entry with a call to [VFSUnregisterDefaultDirectory\(\)](#) before re-registering it with `VFSRegisterDefaultDirectory`.

The specified directory registered for a given file type is intended to be the “root” default directory. If a given default directory has one or more subdirectories, applications should also search those subdirectories for files of the appropriate type.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSGetDefaultDirectory\(\)](#)

## VFSRemoveFSLib Function

|                      |                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Remove a file system library from the library table, so that the VFS Manager can no longer use it.                                                                                                                                                                                                                                                   |
| <b>Declared In</b>   | <code>VfsMgr.h</code>                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>     | <code>Err VFSRemoveFSLib (UInt16 fsLibRefNum)</code>                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>    | <p>→ <i>fsLibRefNum</i></p> <p>Library reference number of the file system library to remove from the library table.</p>                                                                                                                                                                                                                             |
| <b>Returns</b>       | <p>Returns one of the following error codes:</p> <p><code>errNone</code><br/>No error.</p> <p><code>expErrNotOpen</code><br/>The file system library necessary for this call has not been installed or has not been opened.</p> <p><code>vfsErrNoFileSystem</code><br/>VFS Manager can not find the file system specified in <i>fsLibRefNum</i>.</p> |
| <b>Comments</b>      | This function is not normally called by applications. It unmounts any volumes that the specified file system may have mounted. It then closes the library and removes it from the library table with <a href="#"><code>SysLibRemove()</code></a> .                                                                                                   |
| <b>Compatibility</b> | Implemented only if the <a href="#">VFS Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                          |

## VFSUnregisterDefaultDirectory Function

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sever the association between a particular file type and a default directory for a given type of card media.                                                                                                          |
| <b>Declared In</b> | <code>VfsMgr.h</code>                                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Err VFSUnregisterDefaultDirectory<br/>(const Char *fileTypeStr, UInt32 mediaType)</code>                                                                                                                        |
| <b>Parameters</b>  | <p>→ <i>fileTypeStr</i></p> <p>Pointer to the file type with which the default directory is associated. This is a null-terminated string that can either be a MIME media type/subtype pair, such as "image/jpeg",</p> |

## Virtual File System Manager

### *VFSVolumeEnumerate*

---

“text/plain”, or “audio/basic”; or a file extension, such as “.jpeg”.

→ *mediaType*

Type of card media for which the default directory is associated. See [Defined Media Types](#) in the [Expansion Manager](#) chapter for the list of accepted values.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`sysErrParamErr`

The `fileTypeStr` parameter is NULL.

`vfsErrFileNotFound`

A default directory could not be found in the registry for the specified file and media type.

---

**Comments** **NOTE:** Caution is advised when using this function, since you may remove another application’s registration, causing data to mysteriously disappear from those applications.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSGetDefaultDirectory\(\)](#),  
[VFSRegisterDefaultDirectory\(\)](#)

## VFSVolumeEnumerate Function

**Purpose** Enumerate the mounted volumes.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeEnumerate (UInt16 *volRefNumP,  
                                UInt32 *volIteratorP)`

**Parameters** ← *volRefNumP*

Pointer to the reference number for the volume represented by the current enumeration, or `vfsInvalidVolRef` if there are no more volumes to be enumerated or an error occurred.

↔ *volIteratorP*

Pointer to a variable that holds the index of the current enumeration. Set the variable to `vfsIteratorStart` prior to the first iteration. Each call to `VFSVolumeEnumerate`

updates the variable to the index of the next volume. When the last volume is reached, the variable pointed to by `volIteratorP` is set to `vfsIteratorStop`.

**Returns** Returns one of the following error codes:

`errNone`

No error

`expErrEnumerationEmpty`

There are no volumes to enumerate.

`sysErrParamErr`

The value pointed to by `volIteratorP` is not valid. This error is also returned when `volIteratorP` is `vfsIteratorStop`.

**Comments** This function returns a pointer to the volume reference number in the `volRefNumP` parameter. In order to traverse all volumes you must make repeated calls to [VFSVolumeEnumerate\(\)](#) inside a loop. Before the first call to `VFSVolumeEnumerate`, the variable pointed to by `volIteratorP` should be initialized to `vfsIteratorStart`. Each iteration then increments `volIteratorP` to the next entry after updating `volRefNumP`. When the last volume is reached, `*volIteratorP` is set to `vfsIteratorStop`. If there are no volumes to enumerate, `VFSVolumeEnumerate` returns `expErrEnumerationEmpty` when first called.

**Example** Below is an example of how to use `VFSVolumeEnumerate`.

---

```
UInt16 volRefNum;
UInt32 volIterator = vfsIteratorStart;

while (volIterator != vfsIteratorStop) {
    err = VFSVolumeEnumerate(&volRefNum, &volIterator);
    if (err == errNone) {
        // Do something with the volRefNum
    } else {
        // handle error... possibly by
        // breaking out of the loop
    }
}
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSVolumeFormat Function

- Purpose** Format and mount the volume installed in a given slot.
- Declared In** `VfsMgr.h`
- Prototype** `Err VFSVolumeFormat (UInt8 flags,  
                          UInt16 fsLibRefNum,  
                          VFSAnyMountParamPtr vfsMountParamP)`
- Parameters**
- *flags*  
Flags that control how the volume should be formatted. Currently, the only flag not reserved is `vfsMountFlagsUseThisFileSystem`. Pass this flag to cause the volume to be formatted using the file system specified by `fsLibRefNum`. Pass zero (0) to have the VFS Manager attempt to format the volume using a file system appropriate to the slot.
  - *fsLibRefNum*  
Reference number of the file system library for which the volume should be formatted. This number is obtained through a call to `SysLibFind()` with the name of the library you want to use. If the `flags` field is not set to `vfsMountFlagsUseThisFileSystem`, this parameter is ignored.
  - ↔ *vfsMountParamP*  
Parameters to be used when formatting the volume and when mounting the volume after it has been formatted. Supply a pointer to either a [VFSSlotMountParamType](#) or a [VFSPoseMountParamType](#) structure. Note that you'll need to cast your structure pointer to a `VFSAnyMountParamPtr`. Set the `mountClass` field to the appropriate value: if you are mounting to an Expansion Manager slot, set `mountClass` to `VFSMountClass_SlotDriver` and initialize `slotLibRefNum` and `slotRefNum` to the appropriate values. See the descriptions of [VFSAnyMountParamType](#), [VFSSlotMountParamType](#), and [VFSPoseMountParamType](#) for information on the fields that make up these data structures.
- Returns** Returns one of the following error codes:
- `errNone`  
No error.

`expErrNotEnoughPower`

There is insufficient battery power to format and/or mount a volume.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments**

The slot driver currently only supports one volume per slot. If the volume is successfully formatted and mounted, the reference number of the mounted volume is returned in `vfsMountParamP->volRefNum`. If the format is unsuccessful or cancelled, `vfsMountParamP->volRefNum` is set to `vfsInvalidVolRef`.

If `vfsMountFlagsUseThisFileSystem` is passed as a flag, `VFSVolumeFormat` attempts to format the volume using the file system library specified by `fsLibRefNum`. Typically the flag parameter is not set. In this case `VFSVolumeFormat` tries to find a compatible library to format the volume, as follows:

1. Check to see if the default file system library feature is set. If it is, and if that file system is installed, it is used to format the volume. You can set the default file system using `FtrSet()`; supply `sysFileCVFSMgr` for the feature creator, and `vfsFtrIDDefaultFS` for the feature number.
2. Check to see if any of the installed file systems are natively supported for the slot on which the VFS Manager is trying to format. If one of them is, it is used to format the volume.
3. If none of the installed file systems can perform the format using the slot's native type, a dialog displays warning the user that their media may become incompatible with other devices if they continue with the format. The user may continue or cancel the format. If the user chooses to continue, `VFSVolumeFormat` formats the volume using the first file system library that was installed.

When calling `VFSVolumeFormat`, the volume can either be mounted or unmounted. The underlying file system library call requires the volume to be unmounted. `VFSVolumeFormat` checks to see if the volume is currently mounted and unmounts it, if

## Virtual File System Manager

### *VFSVolumeGetLabel*

---

necessary, using [VFSVolumeUnmount](#) before making the file system call. If the file system successfully formats the volume, VFSVolumeFormat mounts it and posts a [sysNotifyVolumeMountedEvent](#) notification.

**Example** The following code excerpt formats a volume on an Expansion Manager slot using a compatible file system.

---

```
VFSslotMountParamType slotParam;
UInt32 slotIterator = expIteratorStart;

slotParam.vfsMountParamP.mountClass =
    VFSMountClass_SlotDriver;
err = ExpSlotEnumerate(&slotParam.slotRefNum,
    &slotIterator);
err = ExpSlotLibFind(slotParam.slotRefNum,
    &slotParam.slotLibRefNum);

err = VFSVolumeFormat(NULL, NULL,
    (VFSAnyMountParamPtr) & slotParam);
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeMount\(\)](#)

## VFSVolumeGetLabel Function

**Purpose** Determine the volume label for a particular volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeGetLabel(UInt16 volRefNum, Char *labelP, UInt16 bufLen)`

**Parameters**

- *volRefNum*  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).
- ← *labelP*  
Pointer to a character buffer into which the volume name is placed.
- *bufLen*  
Length, in bytes, of the *labelP* buffer.

**Returns** Returns one of the following error codes:

errNone

No error.

expErrNotOpen

The file system library necessary for this call has not been installed or has not been opened.

vfsErrNoFileSystem

The VFS Manager cannot find an appropriate file system to handle the request.

vfsErrVolumeBadRef

The specified volume has not been mounted.

vfsErrBufferOverflow

The value specified in bufLen is not big enough to receive the full volume label.

vfsErrNameShortened

There was an error reading the full volume name. A shortened version is being returned.

**Comments** Volume reference numbers can change each time you mount a given volume. To keep track of a particular volume, save the volume's label rather than its reference number. Volume labels can be up to 255 characters long. They can contain any normal character, including spaces and lower case characters, in any character set as well as the following special characters: \$ % ' - \_ @ ~ ` ! ( ) ^ # & + , ; = [ ].

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeSetLabel\(\)](#)

## VFSVolumeInfo Function

**Purpose** Get information about the specified volume.

**Declared In** VfsMgr.h

**Prototype** Err VFSVolumeInfo(UInt16 volRefNum,  
VolumeInfoType \*volInfoP)

**Parameters** → volRefNum  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).

## Virtual File System Manager

### *VFSVolumeMount*

---

← *volInfoP*

Pointer to the structure that receives the volume information for the specified volume. See [VolumeInfoType](#) for more information on the fields in this data structure.

**Returns** Returns one of the following error codes:

*errNone*

No error.

*expErrNotOpen*

The file system library necessary for this call has not been installed or has not been opened.

*vfsErrNoFileSystem*

The VFS Manager cannot find an appropriate file system to handle the request.

*vfsErrVolumeBadRef*

The specified volume reference number is invalid.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeGetLabel\(\)](#), [VFSVolumeSize\(\)](#)

## VFSVolumeMount Function

**Purpose** Mount the card's volume on the specified slot.

**Declared In** *VfsMgr.h*

**Prototype** `Err VFSVolumeMount (UInt8 flags,  
                          UInt16 fsLibRefNum,  
                          VFSAnyMountParamPtr vfsMountParamP)`

**Parameters** → *flags*

Flags that control how the volume should be mounted.

Currently, the only flag not reserved is

*vfsMountFlagsUseThisFileSystem*. Pass this flag to cause the volume to be mounted using the file system specified by *fsLibRefNum*. Pass zero (0) to have the VFS Manager attempt to mount the volume using a file system appropriate for the slot.

→ *fsLibRefNum*

Reference number of the file system library for which the volume should be mounted. This number is obtained

through a call to [SysLibFind\(\)](#) with the name of the library you want to use. If the `flags` field is not set to `vfsMountFlagsUseThisFileSystem`, this parameter is ignored.

↔ `vfsMountParamP`

Parameters to be used when mounting the volume after it has been formatted. Supply a pointer to either a [VFSSlotMountParamType](#) or a [VFSPoSEMountParamType](#) structure. Note that you'll need to cast your structure pointer to a `VFSAnyMountParamPtr`. Set the `mountClass` field to the appropriate value: if you are mounting to an Expansion Manager slot, set `mountClass` to `VFSMountClass_SlotDriver` and initialize `slotLibRefNum` and `slotRefNum` to the appropriate values. See the descriptions of [VFSAnyMountParamType](#), [VFSSlotMountParamType](#), and [VFSPoSEMountParamType](#) for information on the fields that make up these data structures.

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotEnoughPower`

There is insufficient battery power to mount a volume.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`sysErrParamErr`

`vfsMountParamP` was initialized to `NULL`.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeStillMounted`

The volume is already mounted with a different file system than was specified in `fsLibRefNum`.

**Comments** The slot driver only supports one volume per slot. The reference number of the mounted volume is returned in `vfsMountParamP->volRefNum`. If `vfsMountFlagsUseThisFileSystem` is passed as a flag, `VFSVolumeMount` attempts to mount the volume using

## Virtual File System Manager

### *VFSVolumeMount*

---

the file system library specified by `fsLibRefNum`. Otherwise `VFSVolumeMount` tries to find a file system library which is able to mount the volume. If none of the installed file system libraries is able to mount the volume, `VFSVolumeMount` attempts to re-format the volume (using [VFSVolumeFormat\(\)](#)) and then mount it. If `VFSVolumeMount` manages to successfully mount the volume, it ends by posting a [sysNotifyVolumeMountedEvent](#) notification.

After `VFSVolumeMount` successfully mounts a volume, it broadcasts `sysNotifyVolumeMountedEvent`. The VFS Manager, upon being notified of this event, searches the newly-mounted volume for `/PALM/start.prc`. If `start.prc` is found in the `/PALM` directory, the VFS Manager copies it to main memory and launches it. If `start.prc` is not found, the VFS Manager switches to the Launcher instead. This behavior can be overridden; see [Card Insertion and Removal](#) in [Chapter 7, "Expansion," Palm OS Programmer's Companion](#), vol. I.

When `VFSVolumeMount` is called, if the volume is already mounted with a different file system than was specified in `fsLibRefNum`, a `vfsErrVolumeStillMounted` error is returned. If the volume is already mounted with the same file system that is specified in `fsLibRefNum`, or if `vfsMountFlagsUseThisFileSystem` is not set, `VFSVolumeMount` returns `errNone` and sets `volRefNumP` to the reference number of the currently mounted volume.

**Example** The following code excerpt mounts a volume on an Expansion Manager slot using a compatible file system.

---

```
VFSslotMountParamType slotParam ;
UInt32 slotIterator = expIteratorStart;

slotParam.vfsMountParamP.mountClass =
    VFSMountClass_SlotDriver;
err = ExpSlotEnumerate(&slotParam.slotRefNum,
    &slotIterator);
err = ExpSlotLibFind(slotParam.slotRefNum,
    &slotParam.slotLibRefNum);

err = VFSVolumeMount(NULL, NULL,
    (VFSAnyMountParamPtr) & slotParam);
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeFormat\(\)](#), [VFSVolumeUnmount\(\)](#)

## VFSVolumeSetLabel Function

**Purpose** Changes the volume label for a mounted volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeSetLabel(UInt16 volRefNum,  
const Char *labelP)`

**Parameters**

- `volRefNum`  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).
- `labelP`  
Pointer to the label to be applied to the specified volume.  
This string must be null-terminated.

**Returns** Returns one of the following error codes:

`errNone`

No error

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrBadName`

The supplied label is invalid.

`vfsErrNameShortened`

Indicates that the label name was too long. A shortened version of the label name was used instead.

`vfsErrVolumeBadRef`

The specified volume has not been mounted.

**Comments** Volume labels can be up to 255 characters long. They can contain any normal character, including spaces and lower case characters, in any character set as well as the following special characters: \$ % ' - \_ @ ~ ` ! ( ) ^ # & + , ; = [ ]. See [Naming Volumes](#) in [Chapter 7](#), “[Expansion](#),” *Palm OS Programmer’s Companion*, vol. I for guidelines on naming.

## Virtual File System Manager

### *VFSVolumeSize*

---

---

**NOTE:** Most clients should not need to call this function. This function may create or delete a file in the root directory, which would invalidate any current calls to [VFSDirEntryEnumerate\(\)](#).

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeGetLabel\(\)](#)

## VFSVolumeSize Function

**Purpose** Determine the total amount of space on a volume, as well as the amount that is currently being used.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeSize(UInt16 volRefNum,  
                  UInt32 *volumeUsedP, UInt32 *volumeTotalP)`

**Parameters**

- `volRefNum`  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).
- ← `volumeUsedP`  
Pointer to a variable that receives the amount of space, in bytes, in use on the volume.
- ← `volumeTotalP`  
Pointer to a variable that receives the total amount of space on the volume, in bytes.

**Returns** Returns one of the following error codes:

- `errNone`  
No error.
- `expErrNotOpen`  
The file system library necessary for this call has not been installed or has not been opened.
- `vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.
- `vfsErrVolumeBadRef`  
The specified volume has not been mounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeInfo\(\)](#)

## VFSVolumeUnmount Function

**Purpose** Unmount the given volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeUnmount (UInt16 volRefNum)`

**Parameters** `→ volRefNum`  
Volume reference number returned from [VFSVolumeEnumerate\(\)](#).

**Returns** Returns one of the following error codes:

`errNone`

No error.

`expErrNotOpen`

The file system library necessary for this call has not been installed or has not been opened.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The specified volume has not been mounted.

**Comments** This function closes any opened files and posts a [sysNotifyVolumeUnmountedEvent](#) notification once the file system is successfully unmounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeMount\(\)](#)

## Application-Defined Functions

### VFSExportProcPtr Function

|                      |                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | User-defined callback function supplied to <a href="#">VFSExportDatabaseToFileCustom()</a> that tracks the progress of the export.                                                                                                                                                                                   |
| <b>Declared In</b>   | VfsMgr.h                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>     | <pre>typedef Err (*VFSExportProcPtr)     (UInt32 totalBytes, UInt32 offset,      void *userDataP)</pre>                                                                                                                                                                                                              |
| <b>Parameters</b>    | <p><b>totalBytes</b><br/>The total number of bytes being exported.</p> <p><b>offset</b><br/>Undefined.</p> <p><b>userDataP</b><br/>Pointer to any application-specific data passed to the callback function. This pointer may be NULL if your callback doesn't need any such data.</p>                               |
| <b>Returns</b>       | Your progress tracker should allow the user to abort the export. Return <code>errNone</code> if the export should continue, or any other value to abort the export process. If you return a value other than <code>errNone</code> , that value will be returned by <a href="#">VFSExportDatabaseToFileCustom()</a> . |
| <b>Comments</b>      | See the <a href="#">Progress Dialogs</a> section in the <i>Palm OS Programmer's Companion</i> , vol. I for more information on writing a progress tracker.                                                                                                                                                           |
| <b>Compatibility</b> | Implemented only if the <a href="#">VFS Manager Feature Set</a> is present.                                                                                                                                                                                                                                          |
| <b>See Also</b>      | <a href="#">VFSExportProcPtr()</a>                                                                                                                                                                                                                                                                                   |

## VFSImportProcPtr Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | User-defined callback function supplied to <a href="#">VFSImportDatabaseFromFileCustom()</a> that tracks the progress of the import.                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b>   | <code>VfsMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>     | <pre>typedef Err (*VFSImportProcPtr)             (UInt32 totalBytes, UInt32 offset,              void *userDataP)</pre>                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>    | <p><code>totalBytes</code><br/>The total number of bytes being imported.</p> <p><code>offset</code><br/>The number of bytes that have already been imported. This value, along with the total number of bytes being imported, allows you to inform the user how far along the import is.</p> <p><code>userDataP</code><br/>Pointer to NY application-specific data passed to the callback function. This pointer may be NULL if your callback doesn't need any such data.</p> |
| <b>Returns</b>       | Your progress tracker should allow the user to abort the import. Return <code>errNone</code> if the import should continue, or any other value to abort the import process. If you return a value other than <code>errNone</code> , that value will be returned by <a href="#">VFSImportDatabaseFromFileCustom()</a> .                                                                                                                                                        |
| <b>Comments</b>      | See the <a href="#">Progress Dialogs</a> section in the <i>Palm OS Programmer's Companion</i> , vol. I for more information on writing a progress tracker.                                                                                                                                                                                                                                                                                                                    |
| <b>Compatibility</b> | Implemented only if the <a href="#">VFS Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>See Also</b>      | <a href="#">VFSExportProcPtr()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Virtual File System Manager

*VFSImportProcPtr*

---

# Windows

---

This chapter provides information about windows by discussing these topics:

- [Window Data Structures](#)
- [Window Constants](#)
- [Window Functions](#)

No resources are associated with window objects.

The header file `Window.h` declares the API that this chapter describes. For more information on windows, see the section “[Text](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Window Data Structures

### CustomPatternType Typedef

**Purpose** The CustomPatternType type holds an 8-by-8 bit pattern that is one bit deep. Each byte specifies a row of the pattern. When drawing, a pattern is tiled to fill a specified region. This pattern is used by [WinFillLine\(\)](#) and [WinFillRectangle\(\)](#).

The [PatternType](#) specifies the name of the current pattern.

**Prototype** `typedef UInt8 CustomPatternType [8];`

**Compatibility** In pre-3.5 systems, the CustomPatternType is an array of 4 16-bit words. Note the size of this data type has not changed.

### DrawStateFlagsType Struct

**Purpose** The DrawStateFlagsType structure defines a set of flags that control how bitmaps and text are scaled. Use [WinSetScalingMode\(\)](#) to

## Windows

### *DrawStateType*

---

set these flags, and [WinGetScalingMode\(\)](#) to obtain the values of these flags.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `DrawStateFlagsType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

**Prototype**

```
typedef struct DrawStateFlagsType {
    UInt16 unscaledBitmaps:1;
    UInt16 unscaledText:1;
    UInt16 unpaddingText:1;
    UInt16 reserved:13;
} DrawStateFlagsType;
```

#### Field Descriptions

|                 |                                                             |
|-----------------|-------------------------------------------------------------|
| unscaledBitmaps | If set, low-density bitmaps are used, unscaled.             |
| unscaledText    | If set, low density fonts are used, unscaled.               |
| unpaddingText   | If set, padding pixels aren't inserted between text glyphs. |
| reserved        | Reserved for future use.                                    |

**Compatibility** Defined only if the [1.5x Display Feature Set](#) is present.

## DrawStateType Struct

**Purpose** The `DrawStateType` structure defines the current drawing state, which is the Palm OS® implementation of a **pen**. This drawing state is saved with [WinPushDrawState\(\)](#) and restored with [WinPopDrawState\(\)](#).

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `DrawStateType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

**Prototype**

```
typedef struct DrawStateType {
    WinDrawOperation transferMode;
    PatternType pattern;
    UnderlineModeType underlineMode;
    FontID fontId;
    FontPtr font;
    CustomPatternType patternData;
    IndexedColorType foreColor;
    IndexedColorType backColor;
    IndexedColorType textColor;
    UInt8 reserved;
    RGBColorType foreColorRGB;
    RGBColorType backColorRGB;
    RGBColorType textColorRGB;
    UInt16 coordinateSystem;
    DrawStateFlagsType flags;
    Fixed16 scale;
    Fixed16 ntvToActiveScale;
    Fixed16 stdToActiveScale;
    Fixed16 activeToStdScale;
} DrawStateType;
```

### Field Descriptions

|              |                                                                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| transferMode | The current transfer mode for color drawing. See <a href="#">WinDrawOperation</a> . Use <a href="#">WinSetDrawMode()</a> to set this value.                                                                                                                    |
| pattern      | The name of the current pattern. See <a href="#">PatternType</a> . If set to customPattern, the patternData field contains the actual pattern. Use <a href="#">WinGetPatternType()</a> and <a href="#">WinSetPatternType()</a> to retrieve and set this value. |

## Windows

### *DrawStateType*

---

|               |                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| underlineMode | The current underline mode. See UnderlineModeType. Use <a href="#">WinSetUnderlineMode()</a> to set this value.                                                                                                                      |
| fontId        | The ID of the current font. Use <a href="#">FntSetFont()</a> to set this value.                                                                                                                                                      |
| font          | A pointer to the current font. Use <a href="#">FntSetFont()</a> to set this value.                                                                                                                                                   |
| patternData   | The current pattern being used by the WinFill functions if pattern is customPattern. See <a href="#">CustomPatternType</a> . Use <a href="#">WinGetPattern()</a> and <a href="#">WinSetPattern()</a> to retrieve and set this value. |
| foreColor     | Index of the current color used for the foreground. Use <a href="#">WinSetForeColor()</a> to set this value. This field is only valid for indexed color bitmaps.                                                                     |
| backColor     | Index of the current color used for the background. Use <a href="#">WinSetBackColor()</a> to set this value. This field is only valid for indexed color bitmaps.                                                                     |
| textColor     | Index of the current color used for text. Use <a href="#">WinSetTextColor()</a> to set this value. This field is only valid for indexed color bitmaps.                                                                               |
| reserved      | Reserved for future use.                                                                                                                                                                                                             |
| foreColorRGB  | RGB value of the current color used for the foreground. Use <a href="#">WinSetForeColorRGB()</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.                      |

|                  |                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| backColorRGB     | RGB value of the current color used for the background. Use <a href="#">WinSetBackColorRGB()</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.                                                                                                        |
| textColorRGB     | RGB value of the current color used for text. Use <a href="#">WinSetTextColorRGB()</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.                                                                                                                  |
| coordinateSystem | Active coordinate system.                                                                                                                                                                                                                                                                                              |
| flags            | A <a href="#">DrawStateFlagsType</a> structure, the contents of which control the scaling of bitmaps and text.                                                                                                                                                                                                         |
| scale            | A fixed point value used to convert from the draw window's active coordinate system to native coordinates. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                              |
| ntvToActiveScale | A fixed point value used to convert from the native coordinate system to the draw window's active coordinate system. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                    |
| stdToActiveScale | A fixed point value used to convert from the standard coordinate system to the draw window's active coordinate system. This field is used internally to convert font metrics, which are stored as standard coordinates. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present. |
| activeToStdScale | The inverse of <code>stdToActive</code> ; the active-to-standard scaling factor. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                                                        |

**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present. The `scale`, `ntvToActiveScale`, `stdToActiveScale`, and `activeToStdScale` fields are defined only if the [High-Density Display Feature Set](#) is present. The `flags` field is defined only if the [1.5x Display Feature Set](#) is present; otherwise, the contents of `flags` are reserved.

## FrameBitsType Struct

**Purpose** The `FrameBitsType` structure specifies attributes of a window's frame.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FrameBitsType` bit field. Never access its bit field members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

**Prototype**

```
typedef union FrameBitsType {
    struct {
        UInt16 cornerDiam    : 8;
        UInt16 reserved_3    : 3;
        UInt16 threeD        : 1;
        UInt16 shadowWidth   : 2;
        UInt16 width         : 2;
    } bits;
    UInt16 word;
} FrameBitsType;
```

### Field Descriptions

|                          |                                                                            |
|--------------------------|----------------------------------------------------------------------------|
| <code>cornerDiam</code>  | Corner radius of frame; maximum is 38.                                     |
| <code>reserved_3</code>  | Reserved.                                                                  |
| <code>threeD</code>      | Set this bit to draw a 3D button. This feature is not currently supported. |
| <code>shadowWidth</code> | Width of shadow.                                                           |

|       |              |
|-------|--------------|
| width | Frame width. |
| word  | Reserved.    |

## FrameType Typedef

**Purpose** The FrameType type specifies a window frame style.

**Prototype** `typedef UInt16 FrameType;`  
The FrameType can be set to one of the defined frame types shown in the table below, or a custom frame type as defined by a [FrameBitsType](#) structure.

| Constant       | Value      | Description                                                                 |
|----------------|------------|-----------------------------------------------------------------------------|
| noFrame        | 0          | No frame                                                                    |
| simpleFrame    | 1          | Plain rectangular frame                                                     |
| rectangleFrame | 1          | Plain rectangular frame                                                     |
| simple3DFrame  | 0x0012     | 3D frame with width of 2. This frame type is not supported.                 |
| roundFrame     | 0x0401     | Round frame with width of 1.                                                |
| boldRoundFrame | 0x0702     | Round frame with width of 2.                                                |
| popupFrame     | 0x0205     | Popup frame style with slight corner roundness, width of 1 and shadow of 1. |
| dialogFrame    | 0x0302     | Dialog frame style with slight corner roundness and width of 2.             |
| menuFrame      | popupFrame | Same as popupFrame .                                                        |

## IndexedColorType Typedef

**Purpose** The IndexedColorType type is used to specify a color by its index value; that is, by its location in a color table. Color tables are defined by the [ColorTableType](#) structure, which is declared in

Bitmap.h. The IndexedColorType can hold a 1, 2, 4, or 8-bit index.

**Prototype** `typedef UInt8 IndexedColorType;`  
**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present.

## PatternType Enum

**Purpose** The PatternType enumerated type specifies a pattern for drawing. This type is returned by [WinGetPatternType\(\)](#) and is used as a parameter to the [WinSetPatternType\(\)](#) function.

**Prototype** `typedef enum {  
    blackPattern,  
    whitePattern,  
    grayPattern,  
    customPattern,  
    lightGrayPattern,  
    darkGrayPattern  
} PatternType;`

### Value Descriptions

|                  |                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| blackPattern     | Pattern with all bits on.                                                                                                                                |
| whitePattern     | Pattern with all bits off.                                                                                                                               |
| grayPattern      | Pattern with alternating on and off bits.                                                                                                                |
| customPattern    | Custom pattern specified by <a href="#">CustomPatternType</a> .                                                                                          |
| lightGrayPattern | Pattern with one out of four bits in each row turned on. This value is defined only if the <a href="#">High-Density Display Feature Set</a> is present.  |
| darkGrayPattern  | Pattern with one out of four bits in each row turned off. This value is defined only if the <a href="#">High-Density Display Feature Set</a> is present. |

These patterns all operate with current foreground and background color instead of black and white. In effect, blackPattern is only black if the current foreground color is black. whitePattern uses

the current background color. `grayPattern` and `customPattern` uses a combination of background and foreground colors.

Patterns are expanded to the destination bit depth by the blitter when drawing patterned lines and filled rectangles.

The three standard gray patterns—`grayPattern`, `lightGrayPattern`, and `darkGrayPattern`—are always drawn by the blitter using the screen density to improve the appearance of gray fills. Custom patterns, however, are stretched as appropriate by the blitter based on the destination density.

**Compatibility** The `lightGrayPattern` and `darkGrayPattern` values are defined only if the [High-Density Display Feature Set](#) is present.

## UnderlineModeType Enum

**Purpose** The `UnderlineModeType` enumerated type specifies possible values for the underline mode stored in [DrawStateType](#).

**Prototype**

```
typedef enum { noUnderline, grayUnderline,
solidUnderline, colorUnderline }
UnderlineModeType;
```

### Value Descriptions

|                             |                                                                         |
|-----------------------------|-------------------------------------------------------------------------|
| <code>noUnderline</code>    | No underline.                                                           |
| <code>grayUnderline</code>  | Underline is drawn using a dotted line in the current foreground color. |
| <code>solidUnderline</code> | Underline is drawn using a solid line in the foreground color.          |
| <code>colorUnderline</code> | Underline is drawn using a solid line in the foreground color.          |

**Compatibility** The `solidUnderline` and `colorUnderline` options are only available in Palm OS 3.1 and higher.

## WindowFlagsType Struct

**Purpose** The WindowFlagsType specifies different window attributes.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the WindowFlagsType bit field. Access it only through the functions described below. Never access its bit field members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

**Prototype**

```
typedef struct WindowFlagsType {
    UInt16 format:1;
    UInt16 offscreen:1;
    UInt16 modal:1;
    UInt16 focusable:1;
    UInt16 enabled:1;
    UInt16 visible:1;
    UInt16 dialog:1;
    UInt16 freeBitmap:1;
    UInt16 reserved :8;
} WindowFlagsType;
```

### Field Descriptions

|           |                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| format    | If set, use the genericFormat. If 0, use screenFormat.<br><br>Screen format is the native format of the video system; windows in this format can be copied to the display faster. The generic format is device-independent. A window cannot be enabled (that is, accept pen input) unless it uses screen format. |
| offscreen | If set, the window is offscreen. If 0, the window is onscreen.                                                                                                                                                                                                                                                   |
| modal     | If set, the window is modal. If 0, the window is not modal. You set this value when you create the window. This value is returned by <a href="#">WinModal()</a> .                                                                                                                                                |

|            |                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------|
| focusable  | If set, the window can accept the focus. If 0, the window does not accept the focus. You set this value when you create the window. |
| enabled    | If set, the window is enabled. If 0, the window is disabled.                                                                        |
| visible    | If set, the window is visible if it is onscreen. If 0, the window is not visible.                                                   |
| dialog     | If set, the window is a form. If 0, the window is not a form. The <a href="#">FrmInitForm()</a> function sets this value.           |
| freeBitmap | If set, free the bitmap when the window is freed. If 0, retain the bitmap after the window is freed.                                |
| reserved   | Reserved for future use. Must be 0.                                                                                                 |

**Compatibility** In OS versions previous to 3.5, the `freeBitmap` flag was not present. Instead, a compressed flag was present, where 0 specified uncompressed and 1 specified compressed. This compressed flag is now part of the [BitmapType](#).

## WindowFormatType Enum

**Purpose** Use this enumeration to specify the window format when creating an offscreen window with the [WinCreateOffscreenWindow\(\)](#) function.

**Prototype**

```
typedef enum {  
    screenFormat = 0,  
    genericFormat,  
    nativeFormat  
} WindowFormatType;
```

**Field Values**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| screenFormat  | The window's bitmap is allocated using the hardware screen's depth, but for backward compatibility the bitmap associated with the offscreen window is always low density, and the window always uses a coordinate system that directly maps offscreen pixels to coordinates.                                                                                                                                                                                          |
| genericFormat | Like screenFormat, except that genericFormat offscreen windows do not accept pen input.                                                                                                                                                                                                                                                                                                                                                                               |
| nativeFormat  | Reflects the actual hardware screen format in all ways, including screen depth, density, and pixel format. Applications must always use the graphic API when drawing to a nativeFormat offscreen window: directly accessing offscreen pixels will produce undefined results. When using this format, the width and height arguments must be specified using the active coordinate system. Like genericFormat, nativeFormat offscreen windows do not accept pen input. |

**Compatibility** WindowFormatType is defined only if the [High-Density Display Feature Set](#) is present.

## WindowType Struct

**Purpose** The WindowType structure represents a window.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the WindowType structure. Access it only through the functions described below. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

**Prototype**

```
typedef struct WindowType {  
    Coord          displayWidthV20;  
    Coord          displayHeightV20;  
    void           *displayAddrV20;
```

```

WindowFlagsType    windowFlags;
RectangleType      windowBounds;
AbsRectType        clippingBounds;
BitmapPtr          bitmapP;
FrameBitsType      frameType;
DrawStateType      *drawStateP;
struct WindowType  *nextWindow;
} WindowType;

```

### Field Descriptions

**displayWidthV20** Width of the window in pre OS 3.5 devices. In OS 3.5, use [WinGetBounds\(\)](#) to return the window width.

**displayHeightV20** Height of the window in pre OS 3.5 devices. In OS 3.5, use [WinGetBounds\(\)](#) to return the window height.

**displayAddrV20** Pointer to the window display memory buffer in pre OS 3.5 devices. In OS 3.5 or later, call [WinGetBitmap\(\)](#) and then [BmpGetBits\(\)](#) to obtain the window's memory buffer.

---

**WARNING!** Writing directly to screen memory will not be supported in all devices.

---

**windowFlags** Window attributes (see [WindowFlagsType](#)).

**windowBounds** Display-relative bounds of the window. Use [WinGetBounds\(\)](#) and [WinSetBounds\(\)](#) to retrieve and set this value.

**clippingBounds** Bounds for clipping any drawing within the window. Use [WinGetClip\(\)](#) and [WinSetClip\(\)](#) to retrieve and set this value.

**bitmapP** Pointer to the window bitmap, which holds the window's contents. Use [WinGetBitmap\(\)](#) to retrieve this value.

**frameType** Frame attributes; see [FrameBitsType](#).

## Windows

### WinDrawOperation

---

|            |                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| drawStateP | Pointer to a state of the current transfer mode, pattern mode, font, underline mode, and colors. See <a href="#">DrawStateType</a> .<br><br>Only one drawing state exists in the system. Each window points to the same structure. |
| nextWindow | Pointer to the next window in a linked list of windows. This linked list of windows is called the active window list. Do not change this field.                                                                                    |

**Compatibility** In OS versions previous to 3.5, this structure is slightly different. Specifically, the `bitmapP` field is instead a `viewOrigin` field of type `PointType` and specified the window origin point on the display. The `drawStateP` was named `gstate` and was of type `GraphicStatePtr`. The complete definition is shown below:

---

```
typedef struct WinTypeStruct {
    Word          displayWidth;
    Word          displayHeight;
    VoidPtr       displayAddr;
    WindowFlagsType windowFlags;
    RectangleType windowBounds;
    AbsRectType   clippingBounds;
    PointType     viewOrigin;
    FrameBitsType frameType;
    GraphicStatePtr gstate;
    struct WinTypeStruct *nextWindow;
} WindowType;
```

---

## WinDrawOperation Enum

**Purpose** The `WinDrawOperation` enumerated type specifies the transfer mode for color drawing. This type is used as a parameter to the [WinCopyRectangle\(\)](#) and [WinSetDrawMode\(\)](#) functions.

**Prototype**

```
typedef enum {winPaint, winErase, winMask, winInvert, winOverlay, winPaintInverse, winSwap} WinDrawOperation;
```

### Value Descriptions

|                              |                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>winPaint</code>        | Write color-matched source pixels to the destination. If a bitmap's <code>hasTransparency</code> flag is set, <code>winPaint</code> behaves like <code>winOverlay</code> instead.                                                                                                                                                                                      |
| <code>winErase</code>        | Write <code>backColor</code> if the source pixel is transparent.                                                                                                                                                                                                                                                                                                       |
| <code>winMask</code>         | Write <code>backColor</code> if the source pixel is not transparent.                                                                                                                                                                                                                                                                                                   |
| <code>winInvert</code>       | Bitwise XOR the color-matched source pixel onto the destination. This mode does not honor the transparent color in any way.                                                                                                                                                                                                                                            |
| <code>winOverlay</code>      | Write color-matched source pixel to the destination if the source pixel is not transparent. Transparent pixels are skipped. For a 1-bit display, the "off" bits are considered to be the transparent color. Note that this definition of <code>winOverlay</code> is new for Palm OS 5: in Palm OS 4.x, the destination is set (only) where the source pixels are "on." |
| <code>winPaintInverse</code> | Invert the source pixel color and then proceed as with <code>winPaint</code> .                                                                                                                                                                                                                                                                                         |
| <code>winSwap</code>         | Swap the <code>backColor</code> and <code>foreColor</code> destination colors if the source is a pattern (the type of pattern is disregarded). If the source is a bitmap, then the bitmap is transferred using <code>winPaint</code> mode instead.                                                                                                                     |

Note that 2-bit, 4-bit, and 8-bit source bitmaps that don't have a color table inherit the system default color table for their given depth. 1-bit sources (bitmap, text, and patterns) that don't have a color table are given a color table where entry 0 is the `backColor` and entry 1 is the `foreColor` (`textColor` for text).

`winSwap` is not a color invert operation, although a pair of `winSwap` operations will restore the original graphics data. This

mode is used by the OS to select and deselect areas of the screen. It changes destination pixels matching the foreground color to the background color, and changes destination pixels matching the background color to the foreground color. It is a mode available for rectangles, lines, and pixels, but not text or bitmaps. This mode ignores the current pattern.

### The Transparent Color

As of Palm OS 4.0, bitmaps have a `hasTransparency` flag and may designate a transparent color. These concepts are augmented somewhat in Palm OS 5 to make the transfer modes more consistent:

- Bitmaps that don't specify any transparent color (text, patterns, and version 0 bitmaps) are assumed to have a transparent color of index 0 and the `hasTransparency` bit is assumed to be `false`.
- When the `hasTransparency` flag is set and the transfer mode is `winPaint`, only the non-transparent pixels are copied to the destination. With text and patterns, the Palm OS assumes that the "off" bits are the ones designated as transparent and acts as if the `hasTransparency` flag is always `false`. This assumption retains backwards compatibility and unifies the use of transparency across all source data.

### Compatibility

This type is implemented only if [3.5 New Feature Set](#) is present. In earlier releases, this type is named `ScrOperation` and its values begin with the prefix `scr` rather than `win`. `WinDrawOperation` is fully compatible with `ScrOperation`. Transparency is only available if [4.0 New Feature Set](#) is present, and as mentioned in "[The Transparent Color](#)" the behavior of the window drawing modes—`winOverlay` in particular—changes slightly if [5.0 New Feature Set](#) is present.

## WinHandle Typedef

### Purpose

The `WinHandle` type is a pointer to a [WindowType](#) structure. Note that this may change.

**Prototype**    `typedef WindowType *WinHandle;`

## WinLineType Struct

**Purpose**    The WinLineType structure defines a line.

**Prototype**    `typedef struct WinLineType {  
                  Coord x1;  
                  Coord y1;  
                  Coord x2;  
                  Coord y2;  
                } WinLineType;`

### Field Descriptions

|    |                                                  |
|----|--------------------------------------------------|
| x1 | X coordinate of the first endpoint of the line.  |
| y1 | Y coordinate of the first endpoint of the line.  |
| x2 | X coordinate of the second endpoint of the line. |
| y2 | Y coordinate of the second endpoint of the line. |

**Compatibility**    This type is implemented only if [3.5 New Feature Set](#) is present.

## WinPtr Typedef

**Purpose**    The WinPtr type is a pointer to a [WindowType](#) structure.

**Prototype**    `typedef WindowType *WinPtr;`

## Window Constants

If the [5.0 New Feature Set](#) or the [High-Density Display Feature Set](#) are present, the following constants are defined:

- [Window Coordinate System Constants](#)

## Windows

### Window Coordinate System Constants

---

## Window Coordinate System Constants

These constants specify the coordinate system to be used when drawing within a given window:

| Constant                | Value | Description                                                                                                                                                                                                                                           |
|-------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCoordinatesNative      | 0     | Use the bitmap's native coordinate system; this enables a 1-to-1 correspondence between coordinates and pixels.                                                                                                                                       |
| kCoordinatesStandard    | 72    | The coordinate system used by most handhelds running Palm OS 4.0 and earlier. On a single-density handheld, there is one screen pixel per standard coordinate. On a high-density screen, there is more than one screen pixel per standard coordinate. |
| kCoordinatesOneAndAHalf | 108   | One and a half times the standard coordinate system.                                                                                                                                                                                                  |
| kCoordinatesDouble      | 144   | Twice the standard coordinate system.                                                                                                                                                                                                                 |
| kCoordinatesTriple      | 216   | Three times the standard coordinate system.                                                                                                                                                                                                           |
| kCoordinatesQuadruple   | 288   | Four times the standard coordinate system.                                                                                                                                                                                                            |

---

**IMPORTANT:** Not all coordinate systems listed in the above table are supported in this version of the [High-Density Display Feature Set](#). For Palm OS 5, only kCoordinatesNative, kCoordinatesStandard, and kCoordinatesDouble are supported.

---

Pass one of these constants as an argument to [WinSetCoordinateSystem\(\)](#). These values are returned by [WinGetCoordinateSystem\(\)](#).

**Compatibility** Defined only if the [High-Density Display Feature Set](#) is present.

## Window Functions

### WinClipRectangle Function

|                    |                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Shrink the rectangle to make it fit within the clipping region of the current draw window.                                                                                                                                                                                                                                                      |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <code>void WinClipRectangle (RectangleType *rP)</code>                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | $\leftrightarrow$ <i>rP</i><br>Pointer to a structure holding the rectangle to clip. The rectangle returned is the intersection of the rectangle passed and the clipping bounds of the draw window.                                                                                                                                             |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | This function does not change the clipping rectangle of the window. To modify the window's clipping rectangle, use the <a href="#">WinSetClip()</a> and <a href="#">WinResetClip()</a> functions.<br><br>The draw window is the window to which all drawing functions send their output. It is returned by <a href="#">WinGetDrawWindow()</a> . |
| <b>See Also</b>    | <a href="#">WinCopyRectangle()</a> , <a href="#">WinDrawRectangle()</a> , <a href="#">WinEraseRectangle()</a> , <a href="#">WinGetClip()</a>                                                                                                                                                                                                    |

### WinCopyRectangle Function

|                    |                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy a rectangular region from one place to another (either between windows or within a single window).                                                                |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                  |
| <b>Prototype</b>   | <code>void WinCopyRectangle (WinHandle srcWin,<br/>WinHandle dstWin,<br/>const RectangleType *srcRect,<br/>Coord destX, Coord destY,<br/>WinDrawOperation mode)</code> |
| <b>Parameters</b>  | $\rightarrow$ <i>srcWin</i><br>Window from which the rectangle is copied. If NULL, use the draw window.                                                                |

## Windows

### *WinCopyRectangle*

---

→ *dstWin*

Window to which the rectangle is copied. If NULL, use the draw window.

→ *srcRect*

Bounds of the region to copy.

→ *destX*

Left bound of the rectangle in destination window.

→ *destY*

Top bound of the rectangle in destination window.

→ *mode*

The method of transfer from the source to the destination window (see [WinDrawOperation](#)).

**Returns** Returns nothing.

**Comments** Copies the bits of the window inside the rectangle region.

If the destination bitmap is compressed, the mode parameter must be `winPaint`, and the destination coordinates must be (0,0). If the width of the destination rectangle is less than 16 pixels or if the destination coordinates are not (0,0), then this function turns off compression for the destination bitmap. Normally, you do not copy to a compressed bitmap. Instead, you copy to an uncompressed bitmap and compress it afterwards.

**Compatibility** In OS versions before 3.5, the mode parameter was defined as type `ScrOperation`. It is defined as type `WinDrawOperation` only if [3.5 New Feature Set](#) is present. `ScrOperation` and `WinDrawOperation` are fully compatible with each other.

In OS versions before 3.5, it was common practice to render a bitmap in an offscreen window and then use `WinCopyRectangle` to draw it on the screen. In version 3.5 and higher, the preferred method of doing this is to use [WinDrawBitmap\(\)](#) or [WinPaintBitmap\(\)](#).

**See Also** [WinDrawBitmap\(\)](#)

## WinCreateBitmapWindow Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create a new offscreen window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | WinHandle WinCreateBitmapWindow<br>(BitmapType *bitmapP, UInt16 *error)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Returns</b>     | <p>Returns the handle of the new window upon success, or NULL if an error occurs. The error parameter contains one of the following:</p> <p><i>errNone</i><br/>No error.</p> <p><i>sysErrParamErr</i><br/>The <i>bitmapP</i> parameter is invalid. The bitmap must be uncompressed and it must have a valid pixel size (1, 2, 4, or 8). It must not be the screen bitmap.</p> <p><i>sysErrNoFreeResource</i><br/>There is not enough memory to allocate a new window structure.</p>                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | <p>Use <code>WinCreateBitmapWindow</code> if you want to draw into a previously created bitmap, such as a bitmap created using <a href="#">BmpCreate()</a>.</p> <p>This function generates a window wrapper for the specified bitmap. The newly created window is offscreen, uses the generic format (for device independence), and is added to the active window list. Use <a href="#">WinSetDrawWindow()</a> to make it the draw window, and then use the window drawing functions to modify the bitmap.</p> <p>When you use this function to create a window and then delete the window with <a href="#">WinDeleteWindow()</a>, the bitmap is <b>not</b> freed when the window is freed.</p> <p><a href="#">WinCreateOffscreenWindow()</a> uses this function to create its offscreen window. If you call <code>WinCreateOffscreenWindow</code></p> |

## Windows

### *WinCreateOffscreenWindow*

---

instead of using this function, the bitmap is freed when `WinDeleteWindow` is called.

The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode\(\)](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode\(\)](#) for information on how to work around this limitation.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinCreateWindow\(\)](#), [WinCreateOffscreenWindow\(\)](#)

## WinCreateOffscreenWindow Function

**Purpose** Create a new offscreen window and add it to the window list.

**Declared In** `Window.h`

**Prototype** `WinHandle WinCreateOffscreenWindow (Coord width,  
Coord height, WindowFormatType format,  
UInt16 *error)`

**Parameters**   
→ *width*  
Width of the window in pixels. The coordinate system you use for this parameter depends upon the value of *format*.

→ *height*  
Height of the window in pixels. The coordinate system you use for this parameter depends upon the value of *format*.

→ *format*  
One of the window formats defined by [WindowFormatType](#).

← *error*  
Pointer to any error this function encounters.

**Returns** Returns the handle of the new window upon success, or NULL if an error occurs. The *error* parameter contains one of the following:

`errNone`  
No error.

`sysErrParamErr`  
The width or height parameter is NULL or the current color table is invalid.

`sysErrNoFreeResource`

There is not enough memory to complete the function.

The debug ROM gives a warning if you try to draw to a bad window address.

**Comments**

Windows created with this routine draw to a memory buffer instead of the display. Use this function for temporary drawing operations such as double-buffering or save-behind operations.

The memory buffer has two formats: screen format and generic format. Screen format is the native format of the video system; windows in this format can be copied to the display faster. The generic format is device-independent. A window cannot be enabled (that is, accept pen input) unless it uses screen format.

This function differs from [WinCreateBitmapWindow\(\)](#) in the following ways:

- `WinCreateOffscreenWindow` creates a new bitmap in the same depth as the current screen.  
`WinCreateBitmapWindow` uses the bitmap you pass in, which may or may not be in the same depth as the current screen.
- `WinCreateOffscreenWindow` uses the screen format you specify. `WinCreateBitmapWindow` always uses `genericFormat` for the format argument.
- When you delete the window created with `WinCreateOffscreenWindow`, its bitmap is freed along with the window. The bitmap used in the `WinCreateBitmapWindow` is not freed when the window is freed.

Note that if you aren't directly accessing the bits of an offscreen window's bitmap but are just using the APIs, you can always pass `nativeFormat` for the screen format even on pre-Palm OS 5 handhelds and things will work as expected. If you need direct access to the bits of the offscreen window's bitmap, however, call [BmpCreate\(\)](#) and then call `WinCreateBitmapWindow`. Because you created the bitmap, you know its format and thus can safely manipulate its bits. Calling `WinCreateOffscreenWindow` with a format argument of `nativeFormat` can result in a bitmap with an unexpected format: the endianness, number of bits per pixel, and so

## Windows

### *WinCreateWindow*

---

on would match the screen and therefore be fastest to draw, but your application wouldn't be able to manipulate the pixels directly.

The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode\(\)](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode\(\)](#) for information on how to work around this limitation.

| <b>Parameters</b>  | <ul style="list-style-type: none"><li>→ <i>bounds</i><br/>Display-relative bounds of the window.</li><li>→ <i>frame</i><br/>Type of frame around the window (see <a href="#">FrameType</a>).</li><li>→ <i>modal</i><br/>true if the window is modal.</li><li>→ <i>focusable</i><br/>true if the window can be the active window.</li><li>← <i>error</i><br/>Pointer to any error encountered by this function.</li></ul> |
| <b>Returns</b>     | <p>Returns the handle of the new window upon success, or NULL if an error occurs. The error parameter contains one of the following:</p> <ul style="list-style-type: none"><li><code>errNone</code><br/>No error.</li><li><code>sysErrNoFreeResource</code><br/>There is not enough memory to complete the operation.</li></ul>                                                                                          |

- Comments** Windows created by this routine draw to the display. See [WinCreateOffscreenWindow\(\)](#) for information on drawing off screen.
- You typically don't call this function directly. Instead, you use [FrmInitForm\(\)](#) to create form windows from a resource. Forms are much more flexible and have better system support. All forms are windows, but not all windows are forms.
- The window is created with the bounds and frame type that you specify and uses the bitmap and drawing state of the current draw window. Its clipping region is reset according to the bounds you specify.
- All window flags are set to 0 except for the modal and focusable flags, which you pass as a parameter to this function. Specifically, newly created windows are disabled and invisible. You must specifically enable the window before the window can accept input. You can do so with [WinSetActiveWindow\(\)](#).
- See Also** [WinDeleteWindow\(\)](#)

## WinDeleteWindow Function

- Purpose** Remove a window from the window list and free the memory used by the window.
- Declared In** `Window.h`
- Prototype** `void WinDeleteWindow (WinHandle winHandle,  
Boolean eraseIt)`
- Parameters**
- *winHandle*  
Handle of window to delete.
  - *eraseIt*  
If true, the window is erased before it is deleted. If false, the window is not erased.
- Returns** Returns nothing.
- Comments** This function frees all memory associated with the window. Windows created using [WinCreateOffscreenWindow\(\)](#) have their bitmaps freed; windows created using [WinCreateWindow\(\)](#) or [WinCreateBitmapWindow\(\)](#) do not.

## Windows

### *WinDisplayToWindowPt*

---

The `eraseIt` parameter affects onscreen windows only; offscreen windows are never erased. As a performance optimization, you might set `eraseIt` to `false` for an onscreen window if you know that you are going to immediately redraw the area anyway. For example, when the form manager closes a form dialog, it restores the area with the save-behind bits it had stored for that form. For this reason, when the form manager deletes the dialog window, it passes `false` for `eraseIt` because the entire area will be redrawn.

## WinDisplayToWindowPt Function

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a display-relative coordinate to a window-relative coordinate. The coordinate returned is relative to the display window.  |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                              |
| <b>Prototype</b>   | <code>void WinDisplayToWindowPt (Coord *extentX,<br/>                              Coord *extentY)</code>                          |
| <b>Parameters</b>  | <code>↔ extentX</code><br>Pointer to x coordinate to convert.<br><br><code>↔ extentY</code><br>Pointer to y coordinate to convert. |
| <b>Returns</b>     | Returns nothing.                                                                                                                   |
| <b>See Also</b>    | <a href="#"><code>WinWindowToDisplayPt()</code></a>                                                                                |

## WinDrawBitmap Function

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a bitmap at the given coordinates in <code>winPaint</code> mode (see <a href="#"><code>WinDrawOperation</code></a> for mode details). |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                      |
| <b>Prototype</b>   | <code>void WinDrawBitmap (BitmapPtr bitmapP, Coord x,<br/>                      Coord y)</code>                                            |
| <b>Parameters</b>  | <code>→ bitmapP</code><br>Pointer to a bitmap.<br><br><code>→ x</code><br>The x coordinate of the top-left corner.                         |

→ *y*

The *y* coordinate of the top-left corner.

**Returns** Returns nothing.

**Comments** If the bitmap has multiple depths (is a bitmap family), the closest match less than or equal to the current draw window depth is used. If such a bitmap does not exist, the bitmap with the closest match greater than the draw window depth is used.

If the bitmap has its own color table, color conversion to the draw window color table will be applied (on OS 3.5 or later). This color conversion is slow and not recommended. Instead of including a color table in the bitmap, consider using [WinPalette\(\)](#) to change the system color table, draw the bitmap, and then change the system color table back when the bitmap is no longer visible.

This function differs from [WinPaintBitmap\(\)](#) in that this function always uses winPaint mode (copy mode) as the transfer mode. WinPaintBitmap uses the current drawing state transfer mode.

**See Also** [WinEraseRectangle\(\)](#)

## WinDrawChar Function

**Purpose** Draw the specified character in the draw window.

**Declared In** `Window.h`

**Prototype** `void WinDrawChar (WChar theChar, Coord x,  
Coord y)`

**Parameters** → *theChar*

The character to draw. This may be either a single-byte character or a multi-byte character.

→ *x*

*x* coordinate of the location where the character is to be drawn (left bound).

→ *y*

*y* coordinate of the location where the character is to be drawn (top bound).

**Returns** Returns nothing.

**Comments** Before calling this function, call [WinSetUnderlineMode\(\)](#) and [FntSetFont\(\)](#) to set the desired underline and font to draw the characters.

This function differs from [WinPaintChar\(\)](#) in that this function always uses winPaint mode (see [WinDrawOperation](#)). This means the on bits are drawn in the text color, the off bits are in the background color, and underlines are in the foreground color. WinPaintChar uses the current drawing state transfer mode instead of winPaint.

**Compatibility** Implemented only if [3.1 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call WinGlueDrawChar. For more information, see [Chapter 75](#), “[PalmOSGlue Library](#).”

---

**NOTE:** Though this function is new in the 3.1 New Feature Set, due to a bug in the 3.1 implementation, when running on Palm OS 3.1 you must link with the PalmOSGlue library and call WinGlueDrawChar, rather than calling WinDrawChar.

---

## WinDrawChars Function

**Purpose** Draw the specified characters in the draw window.

**Declared In** Window.h

**Prototype** void WinDrawChars (const Char \*chars, Int16 len, Coord x, Coord y)

**Parameters**

- *chars*  
Pointer to the characters to draw.
- *len*  
Length in bytes of the characters to draw.
- *x*  
x coordinate of the first character to draw (left bound).

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | → <i>y</i><br>y coordinate of the first character to draw (top bound).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Returns</b>  | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b> | <p>This function is useful for printing non-editable status or warning messages on the screen.</p> <p>Before calling this function, call <a href="#">WinSetUnderlineMode()</a> and <a href="#">FntSetFont()</a> to set the desired underline and font to draw the characters.</p> <p>This function differs from <a href="#">WinPaintChars()</a> in that this function always uses winPaint mode (see <a href="#">WinDrawOperation</a>). This means the on bits are drawn in the text color, the off bits are in the background color, and underlines are in the foreground color. WinPaintChar uses the current drawing state transfer mode instead of winPaint.</p> |

## WinDrawGrayLine Function

|                    |                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a dashed line in the draw window.                                                                                                                                                                                        |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                      |
| <b>Prototype</b>   | void WinDrawGrayLine (Coord x1, Coord y1,<br>Coord x2, Coord y2)                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <i>x1</i><br/>x coordinate of line start point.</p> <p>→ <i>y1</i><br/>y coordinate of line start point.</p> <p>→ <i>x2</i><br/>x coordinate of line endpoint.</p> <p>→ <i>y2</i><br/>y coordinate of line endpoint.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                              |

## Windows

### *WinDrawGrayRectangleFrame*

---

- Comments** This routine does not draw in the gray color; it draws with alternating foreground and background pixels. That is, it uses the grayPattern pattern type.
- See Also** [WinDrawLine\(\)](#), [WinEraseLine\(\)](#), [WinFillLine\(\)](#), [WinInvertLine\(\)](#), [WinPaintLine\(\)](#), [WinPaintLines\(\)](#)

## WinDrawGrayRectangleFrame Function

- Purpose** Draw a gray rectangular frame in the draw window.
- Declared In** Window.h
- Prototype** void WinDrawGrayRectangleFrame (FrameType frame, const RectangleType \*rP)
- Parameters** → *frame*  
Type of frame to draw (see [FrameType](#)).  
→ *rP*  
Pointer to the rectangle to frame.
- Returns** Returns nothing.
- Comments** This routine does not draw in the gray color; it draws with alternating foreground and background pixels. The standard gray pattern is not used by this routine; rather, the frame is drawn so that the top-left pixel of the frame is always on.
- See Also** [WinDrawRectangleFrame\(\)](#), [WinEraseRectangleFrame\(\)](#), [WinGetFramesRectangle\(\)](#), [WinInvertRectangleFrame\(\)](#), [WinPaintRectangleFrame\(\)](#)

## WinDrawInvertedChars Function

- Purpose** Draw the specified characters inverted (background color) in the draw window.
- Declared In** Window.h
- Prototype** void WinDrawInvertedChars (const Char \*chars, Int16 len, Coord x, Coord y)
- Parameters** → *chars*  
Pointer to the characters to draw.

→ *len*

Length in bytes of the characters to draw.

→ *x*

x coordinate of the first character to draw (left bound).

→ *y*

y coordinate of the first character to draw (top bound).

**Returns** Returns nothing.

**Comments** This routine draws the **on** bits and any underline in the background color and the **off** bits in the text color. (Black and white uses copy NOT mode.) This is the standard function for drawing inverted text.

Before calling this function, consider calling  
[WinSetUnderlineMode\(\)](#) and [FntSetFont\(\)](#).

**See Also** [WinDrawChar\(\)](#), [WinDrawChars\(\)](#), [WinDrawTruncChars\(\)](#),  
[WinEraseChars\(\)](#), [WinInvertChars\(\)](#), [WinPaintChar\(\)](#),  
[WinPaintChars\(\)](#)

## WinDrawLine Function

**Purpose** Draw a line in the draw window using the current foreground color.

**Declared In** `Window.h`

**Prototype** `void WinDrawLine (Coord x1, Coord y1, Coord x2,  
Coord y2)`

**Parameters** → *x1*

x coordinate of line start point.

→ *y1*

y coordinate of line start point.

→ *x2*

x coordinate of line endpoint.

→ *y2*

y coordinate of line endpoint.

**Returns** Returns nothing.

- Comments** This function differs from [WinPaintLine\(\)](#) in that it always uses winPaint mode (see [WinDrawOperation](#)). WinPaintLine uses the current drawing state transfer mode instead of winPaint.
- See Also** [WinDrawGrayLine\(\)](#), [WinEraseLine\(\)](#), [WinFillLine\(\)](#), [WinInvertLine\(\)](#), [WinPaintLine\(\)](#), [WinPaintLines\(\)](#)

## WinDrawPixel Function

- Purpose** Draw a pixel in the draw window using the current foreground color.
- Declared In** Window.h
- Prototype** void WinDrawPixel (Coord x, Coord y)
- Parameters**
- x  
Pointer to the x coordinate of a pixel.
  - y  
Pointer to the y coordinate of a pixel.
- Returns** Returns nothing. May display a fatal error message if the draw window's bitmap is compressed.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [WinErasePixel\(\)](#), [WinInvertPixel\(\)](#), [WinPaintPixel\(\)](#), [WinPaintPixels\(\)](#)

## WinDrawRectangle Function

- Purpose** Draw a rectangle in the draw window using the current foreground color.
- Declared In** Window.h
- Prototype** void WinDrawRectangle (const RectangleType \*rP, UInt16 cornerDiam)
- Parameters**
- rP  
Pointer to the rectangle to draw.
  - cornerDiam  
Radius of rounded corners. Specify zero for square corners.
- Returns** Returns nothing.

- Comments** The `cornerDiam` parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides. This function differs from [WinPaintRectangle\(\)](#) in that it always uses `winPaint` mode (see [WinDrawOperation](#)). `WinPaintRectangle` uses the current drawing state transfer mode instead of `winPaint`.
- See Also** [WinEraseRectangle\(\)](#), [WinFillRectangle\(\)](#), [WinInvertRectangle\(\)](#)

## WinDrawRectangleFrame Function

- Purpose** Draw a rectangular frame in the draw window using the current foreground color.
- Declared In** `Window.h`
- Prototype**

```
void WinDrawRectangleFrame (FrameType frame,  
                             const RectangleType *rP)
```
- Parameters**
- *frame*  
Type of frame to draw (see [FrameType](#)).
  - *rP*  
Pointer to the rectangle to frame.
- Returns** Returns nothing.
- Comments** The frame is drawn outside the specified rectangle. This function differs from [WinPaintRectangleFrame\(\)](#) in that it always uses `winPaint` mode (see [WinDrawOperation](#)). `WinPaintRectangleFrame` uses the current drawing state transfer mode instead of `winPaint`.
- See Also** [WinDrawGrayRectangleFrame\(\)](#), [WinEraseRectangleFrame\(\)](#), [WinGetFramesRectangle\(\)](#), [WinInvertRectangleFrame\(\)](#)

## WinDrawTruncChars Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Draw the specified characters in the draw window, truncating the characters to the specified width.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>     | <pre>void WinDrawTruncChars (const Char *chars,<br/>                        Int16 len, Coord x, Coord y, Coord maxWidth)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>      | <p>Before calling this function, consider calling <a href="#">WinSetUnderlineMode()</a> and <a href="#">FntSetFont()</a>.</p> <p>If drawing all of the specified characters requires more space than <i>maxWidth</i> allows, <code>WinDrawTruncChars</code> draws one less than the number of characters that can fit in <i>maxWidth</i> and then draws an ellipsis (...) in the remaining space. (If the boundary characters are narrower than the ellipsis, more than one character may be dropped to make room.) If <i>maxWidth</i> is narrower than the width of an ellipsis, nothing is drawn.</p> <p>Use this function to truncate text that may contain multi-byte characters.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.1 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>WinGlueDrawTruncChars</code> . For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                                                                                                                                            |

---

**NOTE:** Though this function is new in the 3.1 New Feature Set, due to a bug in the 3.1 implementation, when running on Palm OS 3.1 you must link with the PalmOSGlue library and call `WinGlueDrawTruncChars`, rather than calling `WinDrawTruncChars`.

## WinEraseChars Function

|                    |                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Erase the specified characters in the draw window.                                                                                                                                                                                                                                                                           |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>void WinEraseChars (const Char *chars, Int16 len,<br/>                    Coord x, Coord y)</pre>                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>chars</i><br/>Pointer to the characters to erase.</p> <p>→ <i>len</i><br/>Length in bytes of the characters to erase.</p> <p>→ <i>x</i><br/>x coordinate of the first character to erase (left bound).</p> <p>→ <i>y</i><br/>y coordinate of the first character to erase (top bound).</p>                           |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | The winMask transfer mode is used to erase the characters. See <a href="#">WinDrawOperation</a> for more information. This has the effect of erasing only the on bits for the characters rather than the entire text rectangle. This function only works if the foreground color is black and the background color is white. |

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Draw a pixel in the draw window using the current background color.                                                                                       |
| <b>Declared In</b>   | Window.h                                                                                                                                                  |
| <b>Prototype</b>     | <code>void WinErasePixel (Coord x, Coord y)</code>                                                                                                        |
| <b>Parameters</b>    | <div><div>→ <i>x</i></div><div>Pointer to the x coordinate of a pixel.</div><div>→ <i>y</i></div><div>Pointer to the y coordinate of a pixel.</div></div> |
| <b>Returns</b>       | Returns nothing.                                                                                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                       |
| <b>See Also</b>      | <a href="#">WinDrawPixel()</a> , <a href="#">WinInvertPixel()</a> , <a href="#">WinPaintPixel()</a> , <a href="#">WinPaintPixels()</a>                    |

## WinEraseRectangle Function

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a rectangle in the draw window using the current background color.                                                                                                                                  |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                 |
| <b>Prototype</b>   | <pre>void WinEraseRectangle (const RectangleType *rP,<br/>                        UInt16 cornerDiam)</pre>                                                                                               |
| <b>Parameters</b>  | <p>→ <i>rP</i><br/>Pointer to the rectangle to erase.</p> <p>→ <i>cornerDiam</i><br/>Radius of rounded corners. Specify zero for square corners.</p>                                                     |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                         |
| <b>Comments</b>    | The <i>cornerDiam</i> parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides. |

## WinEraseRectangleFrame Function

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a rectangular frame in the draw window using the current background color.                                                                                                                                              |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>void WinEraseRectangleFrame (FrameType frame,<br/>                             const RectangleType *rP)</pre>                                                                                                           |
| <b>Parameters</b>  | <p>→ <i>frame</i><br/>Type of frame to draw (see <a href="#">FrameType</a>).</p> <p>→ <i>rP</i><br/>Pointer to the rectangle to frame.</p>                                                                                   |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                             |
| <b>See Also</b>    | <a href="#">WinDrawGrayRectangleFrame()</a> ,<br><a href="#">WinDrawRectangleFrame()</a> , <a href="#">WinGetFramesRectangle()</a> ,<br><a href="#">WinInvertRectangleFrame()</a> , <a href="#">WinPaintRectangleFrame()</a> |

## WinEraseWindow Function

|                    |                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Erase the contents of the draw window.                                                                                                                                                                                   |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                 |
| <b>Prototype</b>   | void WinEraseWindow (void)                                                                                                                                                                                               |
| <b>Parameters</b>  | None.                                                                                                                                                                                                                    |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                         |
| <b>Comments</b>    | <a href="#">WinEraseRectangle()</a> is used to erase the window. This routine doesn't erase the frame around the draw window. See <a href="#">WinEraseRectangleFrame()</a> and <a href="#">WinGetWindowFrameRect()</a> . |

## WinFillLine Function

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Fill a line in the draw window with the current pattern.                                                                                                                                                                                      |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | void WinFillLine (Coord x1, Coord y1, Coord x2, Coord y2)                                                                                                                                                                                     |
| <b>Parameters</b>  | <div>→ <i>x1</i><br/>x coordinate of line start point.</div> <div>→ <i>y1</i><br/>y coordinate of line start point.</div> <div>→ <i>x2</i><br/>x coordinate of line endpoint.</div> <div>→ <i>y2</i><br/>y coordinate of line endpoint.</div> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                              |
| <b>Comments</b>    | You can set the current pattern with <a href="#">WinSetPattern()</a> .                                                                                                                                                                        |
| <b>See Also</b>    | <a href="#">WinDrawGrayLine()</a> , <a href="#">WinDrawLine()</a> , <a href="#">WinEraseLine()</a> , <a href="#">WinInvertLine()</a> , <a href="#">WinPaintLine()</a> , <a href="#">WinPaintLines()</a>                                       |

## WinFillRectangle Function

|                    |                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a rectangle in the draw window with current pattern.                                                                                                                                                                                                                                    |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>void WinFillRectangle (const RectangleType *rP,<br/>                        UInt16 cornerDiam)</pre>                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>rP</i><br/>Pointer to the rectangle to draw.</p> <p>→ <i>cornerDiam</i><br/>Radius of rounded corners. Specify zero for square corners.</p>                                                                                                                                          |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | <p>You can set the current pattern with <a href="#">WinSetPattern()</a>.</p> <p>The <i>cornerDiam</i> parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.</p> |

## WinGetActiveWindow Function

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the window handle of the active window.                                                                                                             |
| <b>Declared In</b> | Window.h                                                                                                                                                   |
| <b>Prototype</b>   | <pre>WinHandle WinGetActiveWindow (void)</pre>                                                                                                             |
| <b>Parameters</b>  | None.                                                                                                                                                      |
| <b>Returns</b>     | Returns the handle of the active window. All user input is directed to the active window.                                                                  |
| <b>See Also</b>    | <a href="#">WinSetActiveWindow()</a> , <a href="#">WinGetDisplayWindow()</a> ,<br><a href="#">WinGetFirstWindow()</a> , <a href="#">WinGetDrawWindow()</a> |

## WinGetBitmap Function

|                      |                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return a pointer to a window's bitmap, which holds the window contents.                                                                                                      |
| <b>Declared In</b>   | Window.h                                                                                                                                                                     |
| <b>Prototype</b>     | BitmapType *WinGetBitmap (WinHandle winHandle)                                                                                                                               |
| <b>Parameters</b>    | → <i>winHandle</i><br>Handle of window from which to get the bitmap.                                                                                                         |
| <b>Returns</b>       | Returns a pointer to the bitmap or NULL if winHandle is invalid.                                                                                                             |
| <b>Comments</b>      | For onscreen windows, the bitmap returned always represents the whole screen. Thus, the top-left corner of the returned bitmap may not be the top-left corner of the window. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                          |

## WinGetBounds Function

|                      |                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the bounds of a window in display-relative coordinates.                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>     | void WinGetBounds (WinHandle winH,<br>RectangleType *rP)                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | → <i>winH</i><br>Handle to a window.<br><br>← <i>rP</i><br>Pointer to a rectangle.                                                                                                                                                                                                                                                                      |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                        |
| <b>Comments</b>      | This function returns in rP the bounds of the window represented by winH. This corresponds to the convention used by <a href="#">WinSetBounds()</a> , because it takes a window handle as an argument.                                                                                                                                                  |
| <b>Compatibility</b> | The implementation of this function changed in Palm OS version 4.0. If <a href="#">4.0 New Feature Set</a> is present, it works as documented here.<br><br>Prior to Palm OS 4.0, WinGetBounds returned the bounds of the draw window, and did not take a window handle as an argument. If an application needed to determine the bounds of an arbitrary |

window, the application would call [WinSetDrawWindow\(\)](#) to temporarily set the draw window to the desired window, then `WinGetBounds` would be called to get the bounds of the draw window, then [WinSetDrawWindow\(\)](#) would be called again to restore the draw window. This is no longer necessary.

As of Palm OS 4.0, an application should use [WinGetDrawWindowBounds\(\)](#) to get the bounds of the draw window.

**See Also**     [WinGetWindowExtent\(\)](#), [WinGetDrawWindowBounds\(\)](#)

## WinGetClip Function

**Purpose**         Return the clipping rectangle of the draw window.

**Declared In**    `Window.h`

**Prototype**      `void WinGetClip (RectangleType *rP)`

**Parameters**     `← rP`  
                    Pointer to a structure to hold the clipping bounds.

**Returns**         Returns nothing.

**See Also**       [WinSetClip\(\)](#)

## WinGetCoordinateSystem Function

**Purpose**         Get the coordinate system

**Declared In**    `Window.h`

**Prototype**      `UInt16 WinGetCoordinateSystem (void)`

**Parameters**     `None.`

**Returns**         Returns a value representing the current coordinate system. See “[Window Coordinate System Constants](#)” on page 1122 for the values that this function can return.

**Comments**      Use this function to determine the active coordinate system. Armed with this information, an application can properly initialize graphic primitive coordinates and dimensions, or can modify the coordinate system with [WinSetCoordinateSystem\(\)](#).

## WinGetDisplayExtent

**See Also** [WinSetCoordinateSystem\(\)](#)

**Returns** Returns nothing.

**See Also** [WinGetDisplayExtent\(\)](#), [WinGetActiveWindow\(\)](#), [WinGetDrawWindow\(\)](#)

## WinGetDrawWindow Function

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the window handle of the current draw window.                                                                 |
| <b>Declared In</b> | Window.h                                                                                                             |
| <b>Prototype</b>   | WinHandle WinGetDrawWindow (void)                                                                                    |
| <b>Parameters</b>  | None.                                                                                                                |
| <b>Returns</b>     | Returns handle of draw window.                                                                                       |
| <b>See Also</b>    | <a href="#">WinGetDisplayWindow()</a> , <a href="#">WinGetActiveWindow()</a> ,<br><a href="#">WinSetDrawWindow()</a> |

## WinGetDrawWindowBounds Function

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the bounds of the draw window.                                                                                                                   |
| <b>Declared In</b> | Window.h                                                                                                                                                |
| <b>Prototype</b>   | void WinGetDrawWindowBounds (RectangleType *rP)                                                                                                         |
| <b>Parameters</b>  | $\leftarrow rP$<br>Pointer to the window bounds.                                                                                                        |
| <b>Returns</b>     | Returns nothing.                                                                                                                                        |
| <b>Comments</b>    | A pointer to the bounds of the draw window is returned. This function is equivalent to <a href="#">WinGetBounds()</a> that was in Palm OS prior to 4.0. |
| <b>See Also</b>    | <a href="#">WinGetBounds()</a>                                                                                                                          |

## WinGetFirstWindow Function

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Purpose</b>     | Return a pointer to the first window in the linked list of windows. |
| <b>Declared In</b> | Window.h                                                            |
| <b>Prototype</b>   | WinHandle WinGetFirstWindow (void)                                  |
| <b>Parameters</b>  | None.                                                               |
| <b>Returns</b>     | Returns handle of first window.                                     |
| <b>Comments</b>    | This function is usually used by the system only.                   |
| <b>See Also</b>    | <a href="#">WinGetActiveWindow()</a>                                |

## WinGetFramesRectangle Function

|                    |                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the rectangle that includes a rectangle together with the specified frame around it.                                                                                                                                                                      |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <pre>void WinGetFramesRectangle (FrameType frame,                              const RectangleType *rP,                              RectangleType *obscuredRect)</pre>                                                                                          |
| <b>Parameters</b>  | <p>→ <i>frame</i><br/>Type of rectangle frame (see <a href="#">FrameType</a>).</p> <p>→ <i>rP</i><br/>Pointer to the rectangle to frame.</p> <p>← <i>obscuredRect</i><br/>Pointer to the rectangle that includes both the specified rectangle and its frame.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                 |
| <b>Comments</b>    | Frames are always drawn around (outside) a rectangle.                                                                                                                                                                                                            |
| <b>See Also</b>    | <a href="#">WinGetWindowFrameRect()</a> , <a href="#">WinGetBounds()</a>                                                                                                                                                                                         |

## WinGetPattern Function

|                    |                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the current fill pattern.                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>void WinGetPattern (CustomPatternType *patternP)</pre>                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p>← <i>patternP</i><br/>Buffer where the current pattern is returned (see <a href="#">CustomPatternType</a>).</p>                                                                                                                                                                                                                                                  |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | <p>The fill pattern is used by <a href="#">WinFillLine()</a> and <a href="#">WinFillRectangle()</a>.</p> <p>This function returns the value of <code>patternData</code> in the current drawing state. (See <a href="#">DrawStateType</a>.) The <code>patternData</code> field is only set if the pattern field is <code>customPattern</code>. Therefore, it's a</p> |

good idea to use [WinGetPatternType\(\)](#) instead of this function on systems that support [WinGetPatternType\(\)](#).

**See Also** [WinSetPattern\(\)](#)

## WinGetPatternType Function

|                      |                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the current pattern type.                                                                                                                                                           |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                   |
| <b>Prototype</b>     | PatternType WinGetPatternType (void)                                                                                                                                                       |
| <b>Parameters</b>    | None.                                                                                                                                                                                      |
| <b>Returns</b>       | Returns the current draw window pattern type (see <a href="#">PatternType</a> ). If the return value is customPattern, you can retrieve the pattern with <a href="#">WinGetPattern()</a> . |
| <b>Comments</b>      | The fill pattern is used by <a href="#">WinFillLine()</a> and <a href="#">WinFillRectangle()</a> .                                                                                         |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                        |
| <b>See Also</b>      | <a href="#">WinSetPatternType()</a>                                                                                                                                                        |

## WinGetPixel Function

|                    |                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the color value of a pixel in the current draw window.                                                                                                                                                                                              |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | IndexedColorType WinGetPixel (Coord x, Coord y)                                                                                                                                                                                                            |
| <b>Parameters</b>  | <div>→ x<br/>Pointer to the x coordinate of a pixel.</div> <div>→ y<br/>Pointer to the y coordinate of a pixel.</div>                                                                                                                                      |
| <b>Returns</b>     | Returns the indexed color value of the pixel. See <a href="#">IndexedColorType</a> . A return value of 0 means either that the coordinates do not lie in the current draw window or that they do and the color of that pixel is index 0 (typically white). |

## Windows

### *WinGetPixelRGB*

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinIndexToRGB\(\)](#)

## WinGetPixelRGB Function

**Purpose** Return the RGB color values of a pixel in the current draw window.

**Declared In** `Window.h`

**Prototype** `Err WinGetPixelRGB (Coord x, Coord y,  
RGBColorType *rgbP)`

**Parameters**

- $\rightarrow x$   
Pointer to the x coordinate of a pixel.
- $\rightarrow y$   
Pointer to the y coordinate of a pixel.
- $\leftarrow rgbP$   
RGB color components of the pixel.

**Returns** Returns `errNone` or `sysErrParamErr`. `sysErrParamErr` is returned when the x or y arguments are  $< 0$  or when they are outside the bounds of the draw window.

**Comments** The RGB color values of the pixel are returned as an [RGBColorType](#). This function can be used with both indexed or direct color modes. A return value of `sysErrParamErr` means that the coordinates do not lie in the current draw window.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## WinGetScalingMode Function

**Purpose** Get the current scaling mode.

**Declared In** `Window.h`

**Prototype** `UInt32 WinGetScalingMode (void)`

**Parameters** None.

**Returns** Returns the current scaling mode. See the description of [WinSetScalingMode\(\)](#) for information on interpreting the returned scaling mode value.

**Compatibility**    Implemented only if the [1.5x Display Feature Set](#) is present.

## WinGetSupportedDensity Function

- Purpose**            Enumerate the various display densities supported by the blitter.
- Declared In**      `Window.h`
- Prototype**        `Err WinGetSupportedDensity (UInt16 *densityP)`
- Parameters**       `↔ densityP`  
                      Pointer to a supported density value. Set this value to zero before calling this function for the first time. Subsequent calls cause this value to be set to one of the display densities supported by the handheld.
- Returns**           Returns `errNone` unless the value you supply in `*densityP` isn't a supported density and isn't zero, in which case this function returns `SysErrParamErr`.
- Comments**        Initialize `*densityP` to zero before your application calls this function for the first time. Repeated calls to `WinGetSupportedDensity` will cause the value pointed to by `densityP` to change; these values represent the supported display densities, in order from low to high density. After the last supported density value, this function sets `*densityP` back to zero.

---

**NOTE:** The densities reported by this function are those that are supported by the blitter. These densities are not necessarily supported by the underlying hardware. A handheld with a low-density screen that is able to scale high-density bitmaps will report that it can handle both high and low density bitmaps. Use [WinScreenGetAttribute\(\)](#) to determine the density of the handheld's screen.

---

Density values are defined in `Bitmap.h`; see the [DensityType](#) enum. Only those values supported by a given handheld will be returned by `WinGetSupportedDensity`. For example, on a handheld with a double-density display this function returns `kDensityLow`, followed by `kDensityDouble`, followed by 0. For each supported density, the inverse scaling factor is supported. In this example, the blitter supports pixel-doubling low-density data

## Windows

### *WinGetWindowExtent*

---

for a double-density destination, and the blitter supports pixel-halving high-density data for a low-density destination.

The value pointed to by `densityP` should only be zero or one of the density values supported by the handheld. If it has any other value when you call `WinGetSupportedDensity`, this function will simply return `sysErrParamErr`.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

## WinGetWindowExtent Function

**Purpose** Return the width and height of the current draw window.

**Declared In** `Window.h`

**Prototype**

```
void WinGetWindowExtent (Coord *extentX,  
                          Coord *extentY)
```

**Parameters**

- $\leftarrow extentX$   
Pointer to the width in pixels of the draw window.
- $\leftarrow extentY$   
Pointer to the height in pixels of the draw window.

**Returns** Returns nothing.

**See Also** [WinGetBounds\(\)](#), [WinGetWindowFrameRect\(\)](#),

## WinGetWindowFrameRect Function

**Purpose** Return a rectangle, in display-relative coordinates, that defines the size and location of a window and its frame.

**Declared In** `Window.h`

**Prototype**

```
void WinGetWindowFrameRect (WinHandle winHandle,  
                             RectangleType *r)
```

**Parameters**

- $\rightarrow winHandle$   
Handle of window whose coordinates are desired.
- $\leftarrow r$   
Pointer to the coordinates of the window.

**Returns** Returns nothing.

**See Also** [WinGetBounds\(\)](#)

## WinIndexToRGB Function

**Purpose** Convert an index in the currently active color table to an RGB value.

**Declared In** `Window.h`

**Prototype** `void WinIndexToRGB (IndexedColorType i,  
RGBColorType *rgbP)`

**Parameters**  $\rightarrow i$

A color index value. See [IndexedColorType](#).

$\leftarrow rgbP$

Pointer to an RGB color value corresponding to the index value  $i$ . See [RGBColorType](#).

**Returns** Returns nothing.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinRGBToIndex\(\)](#)

## WinInvertChars Function

**Purpose** Invert the specified characters in the draw window.

**Declared In** `Window.h`

**Prototype** `void WinInvertChars (const Char *chars, Int16 len,  
Coord x, Coord y)`

**Parameters**  $\rightarrow chars$

Pointer to the characters to invert.

$\rightarrow len$

Length in bytes of the characters to invert.

$\rightarrow x$

x coordinate of the first character to invert (left bound).

$\rightarrow y$

y coordinate of the first character to invert (top bound).

**Returns** Returns nothing.

## Windows

### *WinInvertLine*

---

**Comments** This function applies the `winInvert` operation of [WinDrawOperation](#) to the characters in the draw window.

To perform color inverting, use [WinSetTextColor\(\)](#) and [WinSetBackColor\(\)](#) to choose the desired colors, and call [WinPaintChar\(\)](#).

**See Also** [WinDrawChar\(\)](#), [WinDrawChars\(\)](#), [WinDrawInvertedChars\(\)](#), [WinDrawTruncChars\(\)](#), [WinEraseChars\(\)](#), [WinPaintChar\(\)](#), [WinPaintChars\(\)](#)

## WinInvertLine Function

**Purpose** Invert a line in the draw window (using the [WinDrawOperation](#) `winInvert`).

**Declared In** `Window.h`

**Prototype** `void WinInvertLine (Coord x1, Coord y1, Coord x2, Coord y2)`

**Parameters**

- `x1`  
x coordinate of line start point.
- `y1`  
y coordinate of line start point.
- `x2`  
x coordinate of line endpoint.
- `y2`  
y coordinate of line endpoint.

**Returns** Returns nothing.

**See Also** [WinDrawGrayLine\(\)](#), [WinDrawLine\(\)](#), [WinEraseLine\(\)](#), [WinFillLine\(\)](#), [WinPaintLine\(\)](#), [WinPaintLines\(\)](#)

## WinInvertPixel Function

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Invert a pixel in the draw window (using the <a href="#">WinDrawOperation</a> winInvert).                                                                 |
| <b>Declared In</b>   | Window.h                                                                                                                                                  |
| <b>Prototype</b>     | <code>void WinInvertPixel (Coord x, Coord y)</code>                                                                                                       |
| <b>Parameters</b>    | <div><div>→ <i>x</i></div><div>Pointer to the x coordinate of a pixel.</div><div>→ <i>y</i></div><div>Pointer to the y coordinate of a pixel.</div></div> |
| <b>Returns</b>       | Returns nothing.                                                                                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                       |
| <b>See Also</b>      | <a href="#">WinDrawPixel()</a> , <a href="#">WinErasePixel()</a> , <a href="#">WinPaintPixel()</a> , <a href="#">WinPaintPixels()</a>                     |

## WinInvertRectangle Function

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Invert a rectangle in the draw window (using the <a href="#">WinDrawOperation</a> winInvert).                                                                                                            |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>void WinInvertRectangle (const RectangleType *rP, UInt16 cornerDiam)</code>                                                                                                                        |
| <b>Parameters</b>  | <div><div>→ <i>rP</i></div><div>Pointer to the rectangle to invert.</div><div>→ <i>cornerDiam</i></div><div>Radius of rounded corners. Specify zero for square corners.</div></div>                      |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                         |
| <b>Comments</b>    | The <i>cornerDiam</i> parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides. |

## Windows

### *WinInvertRectangleFrame*

---

The operating system itself does not use the inverting routines. Instead, it uses the winSwap transfer mode, or it changes the color selection and uses the WinPaint... routines.

**See Also** [WinDrawRectangle\(\)](#), [WinEraseRectangle\(\)](#), [WinFillRectangle\(\)](#), [WinPaintRectangle\(\)](#)

## WinInvertRectangleFrame Function

**Purpose** Invert a rectangular frame in the draw window (using the [WinDrawOperation](#) winInvert).

**Declared In** Window.h

**Prototype** void WinInvertRectangleFrame (FrameType frame, const RectangleType \*rP)

**Parameters** → *frame*  
Type of frame to draw (see [FrameType](#)).

→ *rP*  
Pointer to the rectangle to frame.

**Returns** Returns nothing.

**See Also** [WinDrawGrayRectangleFrame\(\)](#), [WinDrawRectangleFrame\(\)](#), [WinEraseRectangleFrame\(\)](#), [WinGetFramesRectangle\(\)](#), [WinPaintRectangleFrame\(\)](#)

## WinModal Function

**Purpose** Return true if the specified window is modal.

**Declared In** Window.h

**Prototype** Boolean WinModal (WinHandle winHandle)

**Parameters** → *winHandle*  
Handle of a window.

**Returns** Returns true if the window is modal, otherwise false.

**Comments** A window is modal if it cannot lose the focus.

**See Also** [FrmAlert\(\)](#), [FrmCustomAlert\(\)](#), [FrmDoDialog\(\)](#)

## WinPaintBitmap Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Draw a bitmap in the current draw window at the specified coordinates with the current draw mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Declared In</b>   | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>     | <code>void WinPaintBitmap (BitmapType *bitmapP, Coord x, Coord y)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | <div><div>→ <i>bitmapP</i><br/>Pointer to a bitmap.</div><div>→ <i>x</i><br/>The x coordinate of the top-left corner.</div><div>→ <i>y</i><br/>The y coordinate of the top-left corner.</div></div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>      | <p>If the bitmap has multiple depths (is a bitmap family), the closest match less than or equal to the current draw window depth is used. If such a bitmap does not exist, the bitmap with the closest match greater than the draw window depth is used.</p> <p>Using <code>WinPaintBitmap</code> is now recommended instead of the previous practice of rendering bitmaps into an offscreen window and then using <a href="#"><code>WinCopyRectangle()</code></a> to draw them on screen.</p> <p>The current draw mode is set by <a href="#"><code>WinSetDrawMode()</code></a>.</p> <p>If the bitmap has its own color table, color conversion to the draw window color table will be applied (on OS 3.5 or later). This color conversion is slow and not recommended. Instead of including a color table in the bitmap, consider using <a href="#"><code>WinPalette()</code></a> to change the system color table, draw the bitmap, and then change the system color table back when the bitmap is no longer visible.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## WinPaintRectangle Function

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a rectangle in the draw window using the current drawing state.                                                                                |
| <b>Declared In</b> | Window.h                                                                                                                                            |
| <b>Prototype</b>   | <pre>void WinPaintRectangle (const RectangleType *rP,<br/>                      UInt16 cornerDiam)</pre>                                            |
| <b>Parameters</b>  | <p>→ <i>rP</i><br/>Pointer to the rectangle to draw.</p> <p>→ <i>cornerDiam</i><br/>Radius of rounded corners. Specify zero for square corners.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                    |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | <p>The <code>cornerDiam</code> parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.</p> <p>This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>See Also</b>      | <a href="#">WinDrawRectangle()</a> , <a href="#">WinEraseRectangle()</a> , <a href="#">WinFillRectangle()</a> , <a href="#">WinInvertRectangle()</a>                                                                                                                                                                                                                                                                                                               |

## WinPaintRectangleFrame Function

|                      |                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Draw a rectangular frame in the draw window using the current drawing state.                                                                                                                                                                                                                            |
| <b>Declared In</b>   | <code>Window.h</code>                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <pre>void WinPaintRectangleFrame (FrameType frame,<br/>                             const RectangleType *rP)</pre>                                                                                                                                                                                      |
| <b>Parameters</b>    | <p>→ <i>frame</i><br/>Type of frame to draw (see <a href="#">FrameType</a>).</p> <p>→ <i>rP</i><br/>Pointer to the rectangle to frame.</p>                                                                                                                                                              |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                        |
| <b>Comments</b>      | <p>The frame is drawn outside the specified rectangle.</p> <p>This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                     |

| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>      | This function allows you to draw a rectangle with a frame width and corner radius specified in the active coordinate system. It is necessary because <a href="#">WinPaintRectangleFrame()</a> doesn't allow you to draw rounded rectangles with a frame width greater than 2. Note that because there isn't a function that parallels either <a href="#">WinDrawRectangleFrame()</a> , <a href="#">WinEraseRectangleFrame()</a> , or <a href="#">WinInvertRectangleFrame()</a> , you must set the drawing mode and colors as appropriate and use <code>WinPaintRoundedRectangleFrame</code> to achieve the desired effect. |
| <b>Compatibility</b> | Implemented only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## WinPaintTiledBitmap Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Parameters</b>    | <p>→ <i>bitmapP</i><br/>Pointer to the bitmap that contains the desired pattern.</p> <p>→ <i>rectP</i><br/>Pointer to the rectangle that is to be filled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Returns</b>       | Returns nothing. On a debug ROM, if either <i>bitmapP</i> or <i>rectP</i> are NULL, an error is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>      | <p>This function makes it possible for an application to define a pattern that is larger than the standard 8 by 8 custom pattern, and to define high-density custom patterns.</p> <p>The pattern is scaled by the blitter using the density of <i>bitmapP</i> and the density of the screen bitmap. <i>bitmapP</i> can be a bitmap family; if it is, the Window Manager selects a bitmap using the same algorithm used by <a href="#">WinPaintBitmap()</a>. As with other patterns, the tiled pattern is anchored to the window's origin.</p> <p>If <i>bitmapP</i> does not match the depth or density of the destination bitmap, the blitter converts the bitmap using a temporary buffer. Note that if there isn't enough heap space for the temporary buffer, <i>WinPaintTiledBitmap</i> will be slow.</p> |
| <b>Compatibility</b> | Implemented only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## WinPalette Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set or retrieve the palette for the draw window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Parameters</b>  | <p>→ <i>operation</i></p> <p>Specify one of the following values:</p> <p><i>winPaletteGet</i><br/>Retrieve the palette. Entries are read from the palette beginning at <i>startIndex</i> and placed into <i>tableP</i> beginning at index 0.</p> <p><i>winPaletteSet</i><br/>Set the palette. Entries from <i>tableP</i> (beginning at index 0) are set into the palette beginning at <i>startIndex</i> in the palette.</p> <p><i>winPaletteSetToDefault</i><br/>Set the palette to the default system palette.</p> <p>→ <i>startIndex</i></p> <p>Identifies where in the palette to start reading or writing. Specify <i>WinUseTableIndexes</i> to indicate that the entries are not to be set or read sequentially; instead, the <i>index</i> value in each <i>RGBColorType</i> entry in <i>tableP</i> determines which slot in the palette is to be set or read. You can use this technique to get or set several discontinuous palette entries with a single function call.</p> <p>→ <i>paletteEntries</i></p> <p>Number of palette entries to get or set.</p> <p>↔ <i>tableP</i></p> <p>A pointer to a buffer of <i>RGBColorType</i> entries that is either read from or written to, depending on the <i>operation</i> parameter; the table entries from 0 to <i>paletteEntries</i> - 1 are affected by this routine.</p> |
| <b>Returns</b>     | <p>Returns one of the following values:</p> <p><i>errNone</i><br/>Success.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

`winErrPalette`

The current draw window does not have a color table, a set operation has overflowed the color table, or one of the entries in `tableP` has an invalid index value

`sysErrParamErr`

The `startIndex` value is invalid.

**Comments**

Here are some examples of how this routine works:

- If `startIndex` is 0 and `paletteEntries` is 10, the first 10 elements of the palette will be set from `tableP` or will be copied into `tableP`.
- If `startIndex` is 10 and `paletteEntries` is 5, then entries 10, 11, 12, 13, and 14 in the palette will be set from or copied to elements 0, 1, 2, 3, and 4 in `tableP`.
- If `startIndex` is `WinUseTableIndexes` and `paletteEntries` is 1, then the index value in the `RGBColorType` of element 0 of `tableP` will be read from or copied to `tableP`; in this case, the index field of the `RGBColorType` will not change.

During a set operation, this function broadcasts the [`sysNotifyDisplayChangeEvent`](#) to notify any interested observer that the color palette has changed.

One use for this function is if you need to display a bitmap that uses a color table other than the one in use by the system. You can attach a custom color table to a bitmap, and if you do, the bitmap is drawn using that color table. However, this is a performance drain. As an optimization, you can use `WinPalette` to change the system color table to match that used by the bitmap, display the bitmap, and use `WinPalette` to reset the color table when the bitmap is no longer visible.

**Compatibility**

Implemented only if [3.5 New Feature Set](#) is present.

## **WinPopDrawState Function**

|                      |                                                                                                                                                                                                                                                        |

| <b>Comments</b>      | <p>Use this routine to save the current draw state before making changes to it using the functions listed in the <a href="#">DrawStateType</a> structure's description. Call <a href="#">WinPopDrawState()</a> to restore the saved settings.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                               |

## WinResetClip Function

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Reset the clipping rectangle of the draw window to the portion of the draw window that is within the bounds of the display. |
| <b>Declared In</b> | Window.h                                                                                                                    |
| <b>Prototype</b>   | <code>void WinResetClip (void)</code>                                                                                       |
| <b>Parameters</b>  | None.                                                                                                                       |
| <b>Returns</b>     | Returns nothing.                                                                                                            |
| <b>See Also</b>    | <a href="#"><u>WinSetClip()</u></a>                                                                                         |

## WinRestoreBits Function

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Copy the contents of the specified window to the draw window and delete the passed window.                                                                                                                                                                |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                  |
| <b>Prototype</b>   | <code>void WinRestoreBits (WinHandle winHandle,<br/>                    Coord destX, Coord destY)</code>                                                                                                                                                  |
| <b>Parameters</b>  | <ul style="list-style-type: none"><li>→ <i>winHandle</i><br/>Handle of window to copy and delete.</li><li>→ <i>destX</i><br/>x coordinate in the draw window to copy to.</li><li>→ <i>destY</i><br/>y coordinate in the draw window to copy to.</li></ul> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                          |
| <b>Comments</b>    | This routine is generally used to restore a region of the display that was saved with <a href="#"><u>WinSaveBit()</u></a> .                                                                                                                               |
| <b>See Also</b>    | <a href="#"><u>WinSaveBit()</u></a>                                                                                                                                                                                                                       |

## WinRGBToIndex Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert an RGB value to the index of the closest color in the currently active color lookup table (CLUT).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <code>IndexedColorType WinRGBToIndex<br/>(const RGBColorType *rgbP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | → <i>rgbP</i><br>Pointer to an RGB color value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Returns</b>     | Returns the index of the closest matching color in the CLUT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | Palm OS 3.5 supports a maximum of 256 colors. The number of possible RGB colors greatly exceeds this amount. For this reason, an exact match may not be available for <i>rgbP</i> . If there is no exact RGB match, then a luminance best-fit is used if the color lookup table is entirely gray scale (red, green, and blue values for each entry are identical), or a shortest-distance fit in RGB space is used if the palette contains colors. RGB shortest distance may not always produce the actual closest perceptible color, but it's relatively fast and works for the system palette. |

`WinRGBToIndex` uses the draw window's color table to return the appropriate color table index. If the draw window does not have a color table, the default color table of the current screen is used.

If the draw window does not have a color table, and if the depth of the draw window and the depth of the screen are different, this function will return an inappropriate index. If this situation exists, the application should either define a color table for the draw window, or use [WinScreenMode\(\)](#) to set the screen depth to the same depth as the draw window before calling `WinRGBToIndex`.

---

**NOTE:** The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode\(\)](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode\(\)](#) for information on how to work around this limitation.

---

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. |

## WinSaveBit Function

|                    |                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create an offscreen window and copy the specified region from the draw window to the offscreen window.                                                                                                                                                                               |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | <pre>WinHandle WinSaveBits<br/>    (const RectangleType *source, UInt16 *error)</pre>                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>source</i><br/>Pointer to the bounds of the region to save, relative to the display.</p> <p>← <i>error</i><br/>Pointer to any error encountered by this function.</p>                                                                                                        |
| <b>Returns</b>     | Returns the handle of the window containing the saved image, or zero if an error occurred.                                                                                                                                                                                           |
| <b>Comments</b>    | <p>The offscreen window is the same size as the region to copy.</p> <p>This function tries to copy the window's bitmap using compressed format if possible. It may display a fatal error message if an error occurs when it tries to shrink the pointer for the compressed bits.</p> |
| <b>See Also</b>    | <a href="#">WinRestoreBits()</a>                                                                                                                                                                                                                                                     |

## WinScaleCoord Function

|                    |                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a single coordinate from the standard coordinate system to the active coordinate system.                                                                                 |
| <b>Declared In</b> | Window.h                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>Coord WinScaleCoord (Coord coord,<br/>    Boolean ceiling)</pre>                                                                                                            |
| <b>Parameters</b>  | <p>→ <i>coord</i><br/>A coordinate in the standard coordinate system.</p> <p>→ <i>ceiling</i><br/>Pass true to round up, false to truncate the fractional part when scaling.</p> |
| <b>Returns</b>     | Returns the coordinate scaled to the active coordinate system.                                                                                                                   |

- Comments** This function converts a coordinate by multiplying it by the coordinate scaling factor, and then truncating or rounding the result to an integer value depending on the value of *ceiling*.
- If the active coordinate system is `kCoordinatesStandard`, the returned coordinate is equal to the supplied coordinate.
- Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.
- See Also** [WinScalePoint\(\)](#), [WinScaleRectangle\(\)](#), [WinUnscaleCoord\(\)](#)

## WinScalePoint Function

- Purpose** Convert a point from the standard coordinate system to the active coordinate system.
- Declared In** `Window.h`
- Prototype**

```
void WinScalePoint (PointType *pointP,  
                    Boolean ceiling)
```
- Parameters**
- $\leftrightarrow$  *pointP*  
Pointer to a `PointType` structure that, before the call, should contain a point's standard coordinate system coordinates. After this function is called the `PointType` structure contains the coordinates of the point scaled to the active coordinate system.
  - $\rightarrow$  *ceiling*  
Pass true to round up, false to truncate the fractional part when scaling.
- Returns** Returns nothing. The coordinates of the point indicated by *pointP* are converted to the active coordinate system.
- Comments** This function converts a point by multiplying its x and y coordinates by the coordinate scaling factor and then truncating or rounding the results depending on the value of *ceiling*.
- If the active coordinate system is `kCoordinatesStandard`, *pointP* is not changed by this function.

**Compatibility**    Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also**    [WinScaleCoord\(\)](#), [WinScaleRectangle\(\)](#),  
[WinUnscalePoint\(\)](#)

## WinScaleRectangle Function

**Purpose**    Convert a rectangle from the standard coordinate system to the active coordinate system.

**Declared In**    `Window.h`

**Prototype**    `void WinScaleRectangle (RectangleType *rectP)`

**Parameters**     $\leftrightarrow$  *rectP*

Pointer to a `RectangleType` structure that, before the call, should contain a rectangle's standard coordinate system coordinates. After this function is called the `RectangleType` structure contains the coordinates of the rectangle scaled to the active coordinate system.

**Returns**    Returns nothing. The coordinates of the rectangle indicated by *rectP* are converted to the native coordinate system.

**Comments**    This function scales the rectangle's `topLeft` and `extent` points by multiplying their `x` and `y` coordinates by the coordinate scaling factor. All values are then truncated, but if either `topLeft.x` or `extent.x` had a fractional part, `extent.x` is incremented by 1 (and, similarly, if either `topLeft.y` or `extent.y` had a fractional part, `extent.y` is incremented by 1).

If the active coordinate system is `kCoordinatesStandard`, *rectP* is not changed by this function.

You can use this function when your gadget handler draws using a more precise coordinate system than the Form Manager and needs to convert the form-based bounds of the gadget to the high-density bounds used by the gadget's drawing function.

**Compatibility**    Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also**    [WinScaleCoord\(\)](#), [WinScalePoint\(\)](#),

## WinScreenGetAttribute Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Get various attributes of the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <pre>Err WinScreenGetAttribute     (WinScreenAttrType selector, UInt32 *attrP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>→ <i>selector</i></p> <p>A value indicating which attribute to return. See the description of <a href="#">WinScreenAttrType</a> in the Comments section, below, for the values you can supply to this parameter.</p> <p>← <i>attrP</i></p> <p>Pointer to a UInt32 into which the specified attribute value is placed by this function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Returns</b>     | Returns <code>errNone</code> if the function successfully retrieved the specified attribute, or <code>sysErrParamErr</code> if <i>selector</i> doesn't represent a screen attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | <p>This function returns many of the attributes that can be obtained with <a href="#">WinScreenMode()</a>. Unlike <a href="#">WinScreenMode</a>, however, this function can also return the number of bytes used by each row in the screen buffer as well as the number of pixels per inch on the screen's x and y axes.</p> <p>Unlike <a href="#">WinScreenMode</a>, you cannot set any attributes with this function. Also, you cannot use this function to obtain the "color enabled" attribute. And unlike <a href="#">WinScreenMode</a>, this function always returns the true screen dimensions; <a href="#">WinScreenMode</a> converts the dimensions to the active coordinate system.</p> <p>Applications can use the screen resolution information to make intelligent decisions about how to draw primitives on Palm Powered handhelds with different screen resolutions.</p> |

### WinScreenAttrType

This enum defines the selectors that can be used with the [WinScreenGetAttribute\(\)](#) function.

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <b>Prototype</b> | <pre>typedef enum {     winScreenWidth,     winScreenHeight,</pre> |
|------------------|--------------------------------------------------------------------|

```
winScreenRowBytes,  
winScreenDepth,  
winScreenAllDepths,  
winScreenDensity,  
winScreenPixelFormat,  
winScreenResolutionX,  
winScreenResolutionY  
} WinScreenAttrType;
```

**Value Descriptions**

|                      |                                                                 |
|----------------------|-----------------------------------------------------------------|
| winScreenWidth       | The width of the screen, in pixels.                             |
| winScreenHeight      | The height of the screen, in pixels.                            |
| winScreenRowBytes    | The number of bytes used by each row in the screen buffer.      |
| winScreenDepth       | The screen depth.                                               |
| winScreenAllDepths   | All screen depths (in bitmap format).                           |
| winScreenDensity     | The screen bitmap's density.                                    |
| winScreenPixelFormat | The <a href="#">PixelFormatType</a> appropriate for the screen. |
| winScreenResolutionX | The number of pixels per inch along the screen's x axis.        |
| winScreenResolutionY | The number of pixels per inch along the screen's y axis.        |

**Compatibility**    Implemented only if the [High-Density Display Feature Set](#) is present.

## WinScreenLock Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | “Lock” the current screen by switching the UI concept of the screen base address to an area that is not reflected on the display.                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>     | UInt8 *WinScreenLock (WinLockInitType initMode)                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | <p>→ <i>initMode</i></p> <p>Indicates how to initialize the new screen area. Specify one of the following values:</p> <ul style="list-style-type: none"><li>winLockCopy<br/>Copy old screen to new.</li><li>winLockErase<br/>Erase new screen to white.</li><li>winLockDontCare<br/>Don't do anything</li></ul>                                                                                                                |
| <b>Returns</b>       | Returns a pointer to the new screen base address, or NULL if this routine fails.                                                                                                                                                                                                                                                                                                                                               |
| <b>Comments</b>      | <p>This routine can be used to “freeze” the display while doing lengthy drawing operations to avoid a flickering effect. Call <a href="#">WinScreenUnlock()</a> to unlock the display and cause it to be updated with any changes. The screen must be unlocked as many times as it is locked to actually update the display.</p> <p>Because this function copies the screen, using it is a relatively expensive operation.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                            |

## WinScreenMode Function

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sets or returns display parameters, including display geometry, bit depth, and color support.                                                                                          |
| <b>Declared In</b> | Window.h                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Err WinScreenMode     (WinScreenModeOperation operation,      UInt32 *widthP, UInt32 *heightP,      UInt32 *depthP, Boolean *enableColorP)</pre>                                  |
| <b>Parameters</b>  | The widthP, heightP, depthP, and enableColorP parameters are used in different ways for different operations. See <a href="#">Comments</a> at the end of this description for details. |

→ *operation*

The work this function is to perform, as specified by one of the following selectors:

`winScreenModeGet`

Return the current settings for the display.

`winScreenModeGetDefaults`

Return the default settings for the display.

`winScreenModeGetSupportedDepths`

Return in `depthP` a hexadecimal value indicating the supported screen depths. The binary representation of this value defines a bitfield in which the value 1 indicates support for a particular display depth. The position representing a particular bit depth corresponds to the value  $2^{(\text{bitDepth}-1)}$ . See the [Example](#) at the end of this function description for more information.

`winScreenModeGetSupportsColor`

Return `true` as the value of the `enableColorP` parameter when color mode can be enabled.

`winScreenModeSet`

Change display settings to the values specified by the other arguments to the `WinScreenMode` function.

`winScreenModeSetToDefaults`

Change display settings to default values.

## Windows

### WinScreenMode

---

↔ *widthP*

Pointer to new/old screen width. For backward compatibility, when operation is `winScreenModeGet` or `winScreenModeGetDefaults`, a single-density width is returned, even if the handheld has a double-density display. Use [WinScreenGetAttribute\(\)](#) to retrieve the true hardware dimensions of the display.

↔ *heightP*

Pointer to new/old screen height. For backward compatibility, when operation is `winScreenModeGet` or `winScreenModeGetDefaults`, a single-density height is returned, even if the handheld has a double-density display. Use [WinScreenGetAttribute\(\)](#) to retrieve the true hardware dimensions of the display.

↔ *depthP*

Pointer to new/old/available screen depth.

↔ *enableColorP*

Pass true to enable color drawing mode. The returned value (when using an operation that returns a value through this parameter) simply indicates whether or not the hardware supports color; its value does not change based on the current screen depth.

**Returns** If no error, returns values as specified by the `operation` argument. Various invalid arguments may cause this function to return a `sysErrParamErr` result code. In rare cases, a failed allocation can cause this function to return a `memErrNotEnoughSpace` error.

**Comments** The `widthP`, `heightP`, `depthP`, and `enableColorP` parameters are used in different ways for different operations. All “get” operations overwrite these values with a result when the function returns. The `winScreenModeSet` operation changes current display parameters when passed valid argument values that are not NULL pointers. The `winScreenModeSetToDefaults` operation ignores values passed for all of these parameters.

[Table 54.1](#) summarizes parameter usage for each operation this function performs.

**Table 54.1 Use of parameters to WinScreenMode function**

| <b>Operation</b>      | <b>winScreenMode...</b> | <b>widthP</b> | <b>heightP</b> | <b>depthP</b> | <b>enableColorP</b> |
|-----------------------|-------------------------|---------------|----------------|---------------|---------------------|
| ...Get                |                         | returned      | returned       | returned      | returned            |
| ...GetDefaults        |                         | returned      | returned       | returned      | returned            |
| ...GetSupportedDepths |                         | ignored       | ignored        | returned      | pass in             |
| ...GetSupportsColor   |                         | ignored       | ignored        | pass in       | returned            |
| ...Set                |                         | pass in       | pass in        | pass in       | pass in             |
| ...SetToDefaults      |                         | ignored       | ignored        | ignored       | ignored             |

This function ignores NULL pointer arguments to the `widthP`, `heightP`, `depthP`, and `enableColorP` parameters; thus, you can pass a NULL pointer for any of these values to leave the current value unchanged. Similarly, when getting values, this function does not return a value for any NULL pointer argument.

If you change the display depth, it is recommended that you restore it to its previous state when your application closes, even though the system sets display parameters back to their default values when launching an application.

Note that none of the other operations interprets the `depth` parameter the same way that `winScreenModeGetSupportedDepths` does. For example, to set the display depth to 8-bit mode, you use 8 (decimal) for the display depth, not 0x80 (128 decimal).

When a window is created, and if the window's associated bitmap does not have its own color table, the window will use the system's default color translation tables when a blitting operation occurs to that window. When the system's bit depth changes, the system's default color translation tables are recalculated based on the new screen depth. When the blit occurs at the new screen depth to the offscreen window, the color translation tables are out of sync.

To work around this system limitation, developers should either:

- allocate offscreen windows after changing the depth, or

## Windows

### WinScreenMode

---

- use [WinCreateBitmapWindow\(\)](#) so that it uses a bitmap with a defined color table.

The latter workaround causes the system to perform color matching when blitting, so the first workaround may be preferred.

#### Compatibility

Implemented only if [3.5 New Feature Set](#) is present. In OS versions prior to 3.5, this function is called `ScrDisplayMode`. The prototype for `ScrDisplayMode` is similar to `WinScreenMode`:

---

```
Err ScrDisplayMode ( ScrDisplayModeOperation operation,  
DWordPtr widthP, DWordPtr heightP,  
DWordPtr depthP, BooleanPtr enableColorP)
```

---

The only other difference between `ScrDisplayMode` and `WinScreenMode` is that the `ScrDisplayModeOperation` constants begin with the prefix `scrDisplayMode` rather than `winScreenMode`.

#### Example

Here are some additional examples of return values provided by the `winScreenModeGetSupportedDepths` mode of the `WinScreenMode` function.

This function indicates support for 4-bit drawing by returning a value of `0x08`, or  $2^3$ , which corresponds to a binary value of `1000`. Support for bit depths of 2 and 1 is indicated by a return value of `0x03`. Support for bit depths of 4, 2, and 1 is indicated by `0x0B`, which is a binary value of `1011`. Support for bit depths of 16, 8, 4 and 2 is indicated by `0x808A`. The figure immediately following depicts this final example graphically.

## WinScrollRectangle Function

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Scroll a rectangle in the draw window.                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <code>void WinScrollRectangle (const RectangleType *rP,<br/>WinDirectionType direction, Coord distance,<br/>RectangleType *vacatedP)</code>                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <div><div>→ <i>rP</i><br/>Pointer to the rectangle to scroll.</div><div>→ <i>direction</i><br/>Direction to scroll (winUp, winDown, winLeft, or winRight).</div><div>→ <i>distance</i><br/>Distance to scroll in pixels.</div><div>← <i>vacatedP</i><br/>Pointer to the rectangle that needs to be redrawn because it has been vacated as a result of the scroll.</div></div> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | The rectangle scrolls within its own bounds. Any portion of the rectangle that is scrolled outside its bounds is clipped.                                                                                                                                                                                                                                                     |

## WinSetActiveWindow Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Make a window the active window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <code>void WinSetActiveWindow (WinHandle winHandle)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <code>→ winHandle</code><br>Handle of a window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>The active window is not actually set in this routine; flags are set to indicate that a window is being exited and another window is being entered. The routine <code>EvtGetEvent</code> sends a <a href="#">winExitEvent</a> and a <a href="#">winEnterEvent</a> when it detects these flags. The active window is set by <code>EvtGetEvent</code> when it sends the <code>winEnterEvent</code>. The draw window is also set to the new active window when the active window is changed.</p> <p>The window is enabled before it is made active.</p> <p>All user input is directed to the active window.</p> |
| <b>See Also</b>    | <a href="#">WinGetActiveWindow()</a> , <a href="#">EvtGetEvent()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## WinSetBackColor Function

|                    |                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the background color to use in subsequent draw operations.                                                                                                                                                                                 |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                          |
| <b>Prototype</b>   | <code>IndexedColorType WinSetBackColor</code><br><code>(IndexedColorType backColor)</code>                                                                                                                                                     |
| <b>Parameters</b>  | <code>→ backColor</code><br>Color to set; specify a value of type <a href="#">IndexedColorType</a> .                                                                                                                                           |
| <b>Returns</b>     | Returns the previous background color index.                                                                                                                                                                                                   |
| <b>Comments</b>    | <p>This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState()</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState()</a> to restore it later.</p> |

To set the foreground color to a predefined UI color default, use [UIColorGetTableEntryIndex\(\)](#) as an input to this function. For example:

---

```
curColor = WinSetBackColor
(UIColorGetTableEntryIndex(UIFieldBackground));
```

---

**Compatibility**      Implemented only if [3.5 New Feature Set](#) is present.

**See Also**            [WinSetForeColor\(\)](#), [WinSetTextColor\(\)](#)

## WinSetBackColorRGB Function

- Purpose**              Set the background color to use in subsequent draw operations.
- Declared In**        `Window.h`
- Prototype**          `void WinSetBackColorRGB  
                         (const RGBColorType *newRgbP,  
                         RGBColorType *prevRgbP)`
- Parameters**        `→ newRgbP`  
                        Color to set; specify a value of type [RGBColorType](#).  
  
                        `← prevRgbP`  
                        Previous color; specify a value of type [RGBColorType](#).
- Returns**             Returns nothing
- Comments**          This function takes new and previous [RGBColorType](#) arguments. It is okay to set `newRgbP` or `prevRgbP` to NULL. If an application only wants to get the current color, the `newRgbP` argument is set to NULL. If the application does not care about the previous color, `prevRgbP` can be set to NULL.
- This function sets the `backColorRGB` field of the [DrawStateType](#) structure to the value specified by `newRgbP`. It then sets the index field of `backColorRGB` to the 8 bit system palette entry that most closely matches the RGB components. Finally, it sets the `backColor` index field of [DrawStateType](#) to this index value.
- This function changes the current drawing state. If necessary, use [WinPushDrawState\(\)](#) to preserve the current drawing state before you set this function and use [WinPopDrawState\(\)](#) to restore it later.

## Windows

### *WinSetBounds*

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [WinSetForeColorRGB\(\)](#), [WinSetTextForeColorRGB\(\)](#)

## WinSetBounds Function

**Purpose** Set the bounds of the window to display-relative coordinates.

**Declared In** `Window.h`

**Prototype** `void WinSetBounds (WinHandle winHandle,  
const RectangleType *rP)`

**Parameters**   
→ *winHandle*  
Handle for the window for which to set the bounds.  
→ *rP*  
Pointer to a rectangle to use for bounds.

**Returns** Returns nothing.

**Comments** A visible window cannot have its bounds modified.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [WinGetBounds\(\)](#)

## WinSetClip Function

**Purpose** Set the clipping rectangle of the draw window.

**Declared In** `Window.h`

**Prototype** `void WinSetClip (const RectangleType *rP)`

**Parameters**   
→ *rP*  
Pointer to a structure holding the clipping bounds.

**Returns** Returns nothing.

**See Also** [WinClipRectangle\(\)](#), [WinSetClip\(\)](#), [WinGetClip\(\)](#)

## WinSetDrawMode Function

|                      |                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Set the transfer mode to use in subsequent draw operations.                                                                                                                                                                             |
| <b>Declared In</b>   | <code>Window.h</code>                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>WinDrawOperation WinSetDrawMode<br/>(WinDrawOperation newMode)</code>                                                                                                                                                             |
| <b>Parameters</b>    | → <i>newMode</i><br>Transfer mode to set; specify one of the <a href="#">WinDrawOperation</a> values.                                                                                                                                   |
| <b>Returns</b>       | Returns the previous transfer mode.                                                                                                                                                                                                     |
| <b>Comments</b>      | This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState()</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState()</a> to restore it later. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                     |

## WinSetCoordinateSystem Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Establish the coordinate system to be used for subsequent drawing operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <code>UInt16 WinSetCoordinateSystem (UInt16 coordSys)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | → <i>coordSys</i><br>The desired coordinate system. Supply one of the values defined in “ <a href="#">Window Coordinate System Constants</a> ” on page 1122.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Returns</b>     | Returns the previous coordinate system value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Comments</b>    | <p>This function modifies the <code>scale</code> field in the draw state (a <a href="#">DrawStateType</a> structure). As when making other modifications to a window’s draw state, applications should call <a href="#">WinPushDrawState()</a> before modifying the coordinate system. To restore the coordinate system, your application can then call <a href="#">WinPopDrawState()</a>.</p> <p>To calculate the draw state <code>scale</code> field, the Window Manager divides the density of the bitmap associated with the draw window</p> |

## Windows

### *WinSetDrawWindow*

---

by `coordSys`. If `coordSys` is `kCoordinatesNative`, the Window Manager sets the scale field to 1.0, which enables 1-to-1 mapping of coordinates to pixels.

If you supply a value of `kCoordinatesStandard` for `coordSys`, subsequent drawing will use the standard coordinate system.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [WinGetCoordinateSystem\(\)](#)

## WinSetDrawWindow Function

**Purpose** Set the draw window. (All drawing operations are relative to the draw window.)

**Declared In** `Window.h`

**Prototype** `WinHandle WinSetDrawWindow (WinHandle winHandle)`

**Parameters**  $\rightarrow$  `winHandle`  
Handle of a window.

**Returns** Returns the previous draw window.

**Compatibility** OS versions before 3.5 allowed you to use `NULL` as a parameter to this function to set the draw window to the display window (or screen window). In version 3.5 and higher, this practice is discouraged. If `winHandle` is `NULL`, the debug ROM sets the draw window to `badDrawWindowValue`, and you are warned if you try to draw to it.

**See Also** [WinGetDrawWindow\(\)](#), [WinSetActiveWindow\(\)](#)

## WinSetForeColor Function

**Purpose** Set the foreground color to use in subsequent draw operations.

**Declared In** `Window.h`

**Prototype** `IndexedColorType WinSetForeColor  
(IndexedColorType foreColor)`

**Parameters**  $\rightarrow$  `foreColor`  
Color to set; specify a value of type [IndexedColorType](#).

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | Returns the previous foreground color index.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Comments</b>      | <p>This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState()</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState()</a> to restore it later.</p> <p>To set the foreground color to a predefined UI color default, use <a href="#">UIColorGetTableEntryIndex()</a> as an input to this function. For example:</p> <hr/> <pre>curColor = WinSetForeColor<br/>          (UIColorGetTableEntryIndex<br/>          (UIObjectForeground));</pre> <hr/> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>See Also</b>      | <a href="#">WinSetBackColor()</a> , <a href="#">WinSetTextColor()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## WinSetForeColorRGB Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the foreground color to use in subsequent draw operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <pre>void WinSetForeColorRGB<br/>    (const RGBColorType *newRgbP,<br/>     RGBColorType *prevRgbP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>newRgbP</i><br/>Color to set; specify a value of type <a href="#">RGBColorType</a>.</p> <p>← <i>prevRgbP</i><br/>Previous color; specify a value of type <a href="#">RGBColorType</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>    | <p>This function takes new and previous <a href="#">RGBColorType</a> arguments. It is okay to set <i>newRgbP</i> or <i>prevRgbP</i> to NULL. If an application only wants to get the current color, the <i>newRgbP</i> argument is set to NULL. If the application does not care about the previous color, <i>prevRgbP</i> can be set to NULL.</p> <p>This function sets the <code>foreColorRGB</code> field of the <a href="#">DrawStateType</a> structure to the value specified by <i>newRgbP</i>. It then sets the index field of <code>foreColorRGB</code> to the 8 bit system palette entry that most</p> |

## Windows

### *WinSetPattern*

---

closely matches the RGB components. Finally, it sets the `foreColor` index field of [DrawStateType](#) to this index value.

This function changes the current drawing state. If necessary, use [WinPushDrawState\(\)](#) to preserve the current drawing state before you set this function and use [WinPopDrawState\(\)](#) to restore it later.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [WinSetBackColorRGB\(\)](#), [WinSetTextColorRGB\(\)](#)

## WinSetPattern Function

**Purpose** Set the current fill pattern.

**Declared In** `Window.h`

**Prototype**

```
void WinSetPattern
    (const CustomPatternType *patternP)
```

**Parameters**  $\rightarrow$  *patternP*  
Pattern to set (see [CustomPatternType](#)).

**Returns** Returns nothing.

**Comments** The fill pattern is used by [WinFillLine\(\)](#) and [WinFillRectangle\(\)](#).

This function changes the current drawing state. If necessary, use [WinPushDrawState\(\)](#) to preserve the current drawing state before you set this function and use [WinPopDrawState\(\)](#) to restore it later.

**See Also** [WinGetPattern\(\)](#)

## WinSetPatternType Function

**Purpose** Set the current pattern type.

**Declared In** `Window.h`

**Prototype**

```
void WinSetPatternType (PatternType newPattern)
```

**Parameters**  $\rightarrow$  *newPattern*  
Pattern type to set for the draw window (see [PatternType](#)).

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>      | <p>This function sets the pattern field of the drawing state to newPattern and sets the patternData field to NULL. To set patternData to a custom pattern use <a href="#">WinSetPattern()</a>.</p> <p>The fill pattern is used by <a href="#">WinFillLine()</a> and <a href="#">WinFillRectangle()</a>.</p> <p>This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState()</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState()</a> to restore it later.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>See Also</b>      | <a href="#">WinGetPatternType()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## WinSetScalingMode Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Controls the scaling of bitmaps and fonts, and the spacing between text glyphs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | UInt32 WinSetScalingMode (UInt32 mode)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>→ <i>mode</i></p> <p>Specifies whether bitmaps and fonts should be scaled, and whether text glyphs should be aligned on standard coordinates. See the Comments section, below, for details on how to construct the mode value.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Returns</b>     | Returns the previous scaling mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | <p>If you need to display a large, low-density bitmap—for instance, a map or a photograph—you can use WinSetScalingMode to draw your bitmap unscaled, allowing the user to see more of the bitmap at one time. If you want to draw more, but smaller, text on a handheld that has a high-density display (including 1.5 and double-density), you can use WinSetScalingMode to draw text unscaled. Finally, when the window coordinate system is set to kCoordinatesOneAndAHalf you can use this function to draw text without padding pixels between glyphs, resulting in more consistent kerning for text.</p> |

## Windows

### Scaling Mode Values

---

On a handheld with a high-density display, if the bitmap being drawn, or the font being used, is part of a family that contains both low- and high-density members, `WinSetScalingMode` controls which member is used. If `kTextScalingOff` is set, for instance, the low-density font is used, unscaled, when drawing subsequent text.

### Scaling Mode Values

Depending on how bitmaps and text should be scaled, OR the appropriate constants from the following table to construct the appropriate scaling mode value.

| Constant                       | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kBitmapScalingOff</code> | 1     | Turning bitmap scaling off causes the blitter to draw the low-density bitmap family member, unscaled, when the application subsequently calls <a href="#">WinDrawBitmap()</a> or <a href="#">WinPaintBitmap()</a> (even if the bitmap family contains a bitmap whose density matches the window's). This causes your bitmaps to be drawn smaller, as if they were being viewed from a distance. The application uses the coordinates passed to <a href="#">WinDrawBitmap</a> and <a href="#">WinCopyRectangle()</a> to determine where the unscaled low-density bitmap is placed within the larger footprint of the high-density bounds. |

| Constant                     | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kTextScalingOff</code> | 2     | Turning text scaling off causes the blitter to render text using the low-density family member of the appropriate font, unscaled, when the application subsequently draws text (even if the font family contains a font whose density matches the window's). This results in smaller-sized text being drawn on the screen.                                                                                                                                              |
| <code>kTextPaddingOff</code> | 4     | When text padding is turned off, the blitter does not insert pixels between glyphs in order to align glyphs on standard coordinates. (Text padding is on by default.) By setting the <code>kTextPaddingOff</code> bit, an application can lay out text using high density coordinates and preserve the native font's internal kerning. This unpadded mode provides the best appearance of text, but requires the application to use the high-density coordinate system. |

When an application calls [WinSetCoordinateSystem\(\)](#) to use native coordinates for a high-density window, the operating system turns off text padding. When an application calls `WinSetCoordinateSystem` to use standard coordinates, the operating system turns text padding on. To use standard coordinates with pixel padding turned off, or to use native coordinates with pixel padding turned on, call `WinSetScalingMode` after calling [WinSetCoordinateSystem\(\)](#). Note that using standard coordinates with padding off is not recommended since the Font Manager API that measures character widths will return inaccurate widths.

The scaling mode flags are part of the window's draw state. In order to ensure that the draw state is properly restored, save that state using [WinPushDrawState\(\)](#) before calling functions that alter the draw state—such as `WinSetScalingMode` or `WinSetCoordinateSystem`. After drawing is completed, restore the draw state with [WinPopDrawState\(\)](#).

## Windows

### *WinSetTextColor*

---

When an application quits, the draw state is restored to the default settings.

**Compatibility** Implemented only if the [1.5x Display Feature Set](#) is present.

**See Also** [WinGetScalingMode\(\)](#)

## WinSetTextColor Function

**Purpose** Set the color to use for drawing characters in subsequent draw operations.

**Declared In** `Window.h`

**Prototype** `IndexedColorType WinSetTextColor  
(IndexedColorType textColor)`

**Parameters**  $\rightarrow$  `textColor`  
Color to set; specify a value of type [IndexedColorType](#).

**Returns** Returns the previous text color index.

**Comments** This function changes the current drawing state. If necessary, use [WinPushDrawState\(\)](#) to preserve the current drawing state before you set this function and use [WinPopDrawState\(\)](#) to restore it later.

To set the foreground color to a predefined UI color default, use [UIColorGetTableEntryIndex\(\)](#) as an input to this function. For example:

---

```
curColor = WinSetTextColor  
(UIColorGetTableEntryIndex(UIFieldText));
```

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinSetBackColor\(\)](#), [WinSetForeColor\(\)](#)

## WinSetTextColorRGB Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Comments</b>      | <p>This function takes new and previous <a href="#">RGBColorType</a> arguments. It is okay to set <i>newRgbP</i> or <i>prevRgbP</i> to NULL. If an application only wants to get the current color, the <i>newRgbP</i> argument is set to NULL. If the application does not care about the previous color, <i>prevRgbP</i> can be set to NULL.</p> <p>This function sets the <code>textColorRGB</code> field of the <a href="#">DrawStateType</a> structure to the value specified by <i>newRgbP</i>. It then sets the index field of <code>textColorRGB</code> to the 8 bit system palette entry that most closely matches the RGB components. Finally, it sets the <code>textColor</code> index field of <a href="#">DrawStateType</a> to this index value.</p> <p>This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState()</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState()</a> to restore it later.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## WinUnscalePoint Function

**Purpose**            Convert a point from the active coordinate system to the standard coordinate system.

**Declared In**      `Window.h`

**Prototype**        `void WinUnscalePoint (PointType *pointP,  
                        Boolean ceiling)`

**Parameters**       $\leftrightarrow$  *pointP*  
                        Pointer to a `PointType` structure that, before the call, should contain a point's coordinates using the active coordinate system. After this function is called the `PointType` structure contains the coordinates of the point scaled to the standard coordinate system.

$\rightarrow$  *ceiling*  
                        Pass true to round up, false to truncate the fractional part when scaling.

**Returns**           Returns nothing. The coordinates of the point indicated by *pointP* are converted to the standard coordinate system.

**Comments**        This function converts a point by dividing its x and y coordinates by the coordinate scaling factor, truncating or rounding the results to integer values depending on the value of *ceiling*. For instance, the input coordinates (11, 13) are transformed to (6, 7) if the input values represent native coordinates on a handheld with a double-density screen and *ceiling* is set to `true`. If *ceiling* is set to `false`, the same input coordinates are transformed to (5, 6).

                        If the active coordinate system is `kCoordinatesStandard`, *pointP* is not changed by this function.

**Compatibility**    Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also**        [WinScalePoint\(\)](#), [WinUnscaleCoord\(\)](#),  
[WinUnscaleRectangle\(\)](#)

## WinUnscaleRectangle Function

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert a rectangle from the active coordinate system to the standard coordinate system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>     | <code>void WinUnscaleRectangle (RectangleType *rectP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | $\leftrightarrow$ <i>rectP</i><br>Pointer to a RectangleType structure that, before the call, should contain a rectangle's coordinates using the active coordinate system. After this function is called the RectangleType structure contains the coordinates of the rectangle scaled to the standard coordinate system.                                                                                                                                                                                                                                               |
| <b>Returns</b>       | Returns nothing. The coordinates of the rectangle indicated by <i>rectP</i> are converted to the standard coordinate system.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>      | <p>This function scales the rectangle's <i>topLeft</i> and <i>extent</i> points by dividing their <i>x</i> and <i>y</i> coordinates by the coordinate scaling factor. All values are then truncated, but if either <i>topLeft.x</i> or <i>extent.x</i> had a fractional part, <i>extent.x</i> is incremented by 1 (and, similarly, if either <i>topLeft.y</i> or <i>extent.y</i> had a fractional part, <i>extent.y</i> is incremented by 1).</p> <p>If the active coordinate system is <i>kCoordinatesStandard</i>, <i>rectP</i> is not changed by this function.</p> |
| <b>Compatibility</b> | Implemented only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>See Also</b>      | <a href="#">WinScaleRectangle()</a> , <a href="#">WinUnscaleCoord()</a> , <a href="#">WinUnscalePoint()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## WinValidateHandle Function

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return <i>true</i> if the specified handle references a valid window object. |
| <b>Declared In</b> | Window.h                                                                     |
| <b>Prototype</b>   | <code>Boolean WinValidateHandle (WinHandle winHandle)</code>                 |
| <b>Parameters</b>  | $\rightarrow$ <i>winHandle</i><br>The handle to be tested.                   |

|                      |                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | Returns <code>true</code> if the specified handle references a non-NULL pointer to a window in the active window list, <code>false</code> if the handle references a window whose values are out of sync with the current system state. |
| <b>Comments</b>      | For debugging purposes only. Do not include this function in commercial applications.                                                                                                                                                   |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                     |
| <b>See Also</b>      | <a href="#">FrmValidatePtr()</a> , <a href="#">FrmRemoveObject()</a>                                                                                                                                                                    |

## WinWindowToDisplayPt Function

|                    |                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a window-relative coordinate to a display-relative coordinate.                                                                  |
| <b>Declared In</b> | <code>Window.h</code>                                                                                                                   |
| <b>Prototype</b>   | <code>void WinWindowToDisplayPt (Coord *extentX,<br/>                                Coord *extentY)</code>                             |
| <b>Parameters</b>  | <p>↔ <i>extentX</i><br/>    Pointer to x coordinate to convert.</p> <p>↔ <i>extentY</i><br/>    Pointer to y coordinate to convert.</p> |
| <b>Returns</b>     | Returns nothing.                                                                                                                        |
| <b>Comments</b>    | The coordinate passed is assumed to be relative to the draw window.                                                                     |
| <b>See Also</b>    | <a href="#">WinDisplayToWindowPt()</a>                                                                                                  |

# Miscellaneous System Functions

---

This chapter describes miscellaneous system functions. The functions in this chapter are declared in the header files `Crc.h`, `DLServer.h`, `IntlMgr.h`, and `Localize.h`.

## Crc16CalcBlock Function

|                    |                                                                                                                                                                                                                             |                   |                             |                    |                                |                  |                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|-----------------------------|--------------------|--------------------------------|------------------|-----------------|
| <b>Purpose</b>     | Calculate the 16-bit CRC of a data block using the table lookup method.                                                                                                                                                     |                   |                             |                    |                                |                  |                 |
| <b>Declared In</b> | <code>Crc.h</code>                                                                                                                                                                                                          |                   |                             |                    |                                |                  |                 |
| <b>Prototype</b>   | <pre>UInt16 Crc16CalcBlock (const void *bufP,<br/>                        UInt16 count, UInt16 crc)</pre>                                                                                                                   |                   |                             |                    |                                |                  |                 |
| <b>Parameters</b>  | <table><tr><td><code>bufP</code></td><td>Pointer to the data buffer.</td></tr><tr><td><code>count</code></td><td>Number of bytes in the buffer.</td></tr><tr><td><code>crc</code></td><td>Seed crc value.</td></tr></table> | <code>bufP</code> | Pointer to the data buffer. | <code>count</code> | Number of bytes in the buffer. | <code>crc</code> | Seed crc value. |
| <code>bufP</code>  | Pointer to the data buffer.                                                                                                                                                                                                 |                   |                             |                    |                                |                  |                 |
| <code>count</code> | Number of bytes in the buffer.                                                                                                                                                                                              |                   |                             |                    |                                |                  |                 |
| <code>crc</code>   | Seed crc value.                                                                                                                                                                                                             |                   |                             |                    |                                |                  |                 |
| <b>Returns</b>     | A 16-bit CRC for the data buffer.                                                                                                                                                                                           |                   |                             |                    |                                |                  |                 |

## DlkControl Function

- Purpose** Perform an operation at the behest of the desktop software. Among other things, this function is used to return values to the conduit during the handling of [sysAppLaunchCmdHandleSyncCallApp](#).
- Declared In** `DLServer.h`
- Prototype** `Err DlkControl (DlkCtlEnum op, void *param1P, void *param2P)`
- Parameters**
- *op*  
Desktop Link control code. Use `dlkCtlSendCallAppReply` when sending a result back to the conduit while handling a `sysAppLaunchCmdHandleSyncCallApp` launch code.
  - ↔ *param1P*  
Pointer to the first parameter (operation-specific). For `dlkCtlSendCallAppReply`, this parameter should point to a [DlkCallAppReplyParamType](#) structure.
  - ↔ *param2P*  
Pointer to the second parameter (operation-specific). For `dlkCtlSendCallAppReply`, this parameter should be set to `NULL`.
- Returns** `errNone` if no error, or an error code if there was a problem during the call to `DlkControl`. In either case, place the value returned from `DlkControl` into the `replyErr` field of the `SysAppLaunchCmdHandleSyncCallAppType` structure when handling `sysAppLaunchCmdHandleSyncCallApp`.
- Comments** This function is needed to return data back to a conduit during the handling of [sysAppLaunchCmdHandleSyncCallApp](#). Set *param1P* to point to a [DlkCallAppReplyParamType](#) structure, as described below. See the [Example](#) on page 1201 for an illustration of how to handle `sysAppLaunchCmdHandleSyncCallApp`.

### DlkCallAppReplyParamType

**Prototype**

```
typedef struct DlkCallAppReplyParamType {
    UInt16 pbSize;
    UInt32 dwResultCode;
    const void *resultP;
    UInt32 dwResultSize;
    void *dlRefP;
```

---

```

        UInt32 dwReserved1;
    } DlkCallAppReplyParamType;

```

**Fields**

**pbSize**  
Size of this parameter block. Set it to `sizeof(DlkCallAppReplyParamType)`.

**dwResultCode**  
Result code to be returned to the remote caller.

**resultP**  
Pointer to result data.

**dwResultSize**  
Size of result data block (number of bytes).

**dlRefP**  
Desktop Link reference pointer from `SysAppLaunchCmdHandleSyncCallAppType`.

**dwReserved1**  
Reserved. Set to NULL.

**Example** The `SysAppLaunchCmdHandleSyncCallAppType` structure that accompanies the [sysAppLaunchCmdHandleSyncCallApp](#) launch code contains all of the information passed into `SyncCallRemoteModule` on the desktop as well as the necessary fields to pass the result pack to the desktop. At the end of your `sysAppLaunchCmdHandleSyncCallApp` launch code handler, you'll need to send a [DlkCallAppReplyParamType](#) reply structure back to the device using `DlkControl`.

---

```

#include <DLServer.h>
...
case sysAppLaunchCmdHandleSyncCallApp:
{
    SysAppLaunchCmdHandleSyncCallAppType *theCommandPtr;
    DlkCallAppReplyParamType theReplyParams;
    CharPtr theReplyBuffer = "SUCCESS";

    // Cast the cmdPBP to a SysAppLaunchCmdHandleSyncCallAppType
    // pointer so that we can work with it.
    theCommandPtr = (SysAppLaunchCmdHandleSyncCallAppType*)cmdPBP;

    // Do whatever work is necessary here.  If you set the m_wActionCode
    // field in your CCallModuleParams class on the desktop, then you
    // can handle that code by looking at the action field of theCommandPtr
    // (i.e.) if (theCommandPtr->action == 1)

```

## Miscellaneous System Functions

### *DlkControl*

---

```
// Create the reply to send back to the desktop

// First clear out all the fields. This is necessary so that the reserved
// fields are set to NULL.
MemSet( &theReplyParams, sizeof(DlkCallAppReplyParamType), 0 );

// Set the size of the reply. This is required.
theReplyParams.pbSize = sizeof(DlkCallAppReplyParamType);

// Set the result code. Normally this will be set to zero unless you want
// to send an error code back to the desktop.
theReplyParams.dwResultCode = 0;

// Fill in the reply buffer and buffer length
theReplyParams.resultP = theReplyBuffer;
theReplyParams.dwResultSize = StrLen(theReplyBuffer) + 1;

// Fill in the DL reference pointer. This is required.
theReplyParams.dlRefP = theCommandPtr->dlRefP;

// Set the handled field to true. This is required to let the desktop
// know that the sysAppLaunchCmdHandleSyncCallApp was handled. If you
// don't set this to true, the call to SyncCallRemoteModule will return
// SYNCERR_UNKNOWN_REQUEST.
theCommandPtr->handled = true;

// Finally, set the replyErr field by passing the reply parameters to
// DlkControl. This is required for the DLServer to properly handle the
// reply request.
theCommandPtr->replyErr = DlkControl (dlkCtlSendCallAppReply,
    &theReplyParams, NULL);

break;
}
```

---

[Table 55.1](#) and [Table 55.2](#) list some important mappings from the CCallModuleParams class on the desktop to the SysAppLaunchCmdHandleSyncCallAppType and DlkCallAppReplyParamType structures on the handheld.

**Table 55.1 CCallModuleParams to SysAppLaunchCmdHandleSyncCallAppType mapping**

| <b>CCallModuleParams</b> | <b>SysAppLaunchCmdHandleSyncCallAppType</b> |
|--------------------------|---------------------------------------------|
| m_wActionCode            | action                                      |
| m_dwParamSize            | dwParamSize                                 |
| m_pParam                 | paramP                                      |

**Table 55.2 CCallModuleParams to DlkCallAppReplyParamType mapping**

| <b>CCallModuleParams</b> | <b>DlkCallAppReplyParamType</b> |
|--------------------------|---------------------------------|
| m_dwResultBufSize        | dwResultSize                    |
| m_pResultBuf             | resultP                         |
| m_dwResultCode           | dwResultCode                    |

## DlkGetSyncInfo Function

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Get the sync info managed by Desktop Link. This function is often used to obtain the user name on the handheld.                                                                                                       |
| <b>Declared In</b> | DLServer.h                                                                                                                                                                                                            |
| <b>Prototype</b>   | <pre>Err DlkGetSyncInfo (UInt32 *succSyncDateP,                     UInt32 *lastSyncDateP,                     DlkSyncStateType *syncStateP, Char *nameBufP,                     Char *logBufP, Int32 *logLenP)</pre> |
| <b>Parameters</b>  | <p>← <i>succSyncDateP</i></p> <p>Pointer to the location where the date of the last successful sync is stored. Supply NULL for this parameter if this date isn't needed.</p>                                          |

## Miscellaneous System Functions

### *DlkGetSyncInfo*

---

← *lastSyncDateP*

Pointer to the location where the date of the last sync, successful or otherwise, is stored. Supply NULL for this parameter if this date isn't needed.

← *syncStateP*

Pointer to a `DlkSyncStateType` enum into which the state of the last sync is stored. Supply NULL for this parameter if the state information isn't needed. See the Comments, below, for a description of this enum.

← *nameBufP*

Pointer to a string buffer into which the null-terminated handheld user name is stored. This string buffer must have been preallocated to be at least `dlkUserNameBufSize` bytes in length. Supply NULL for this parameter if the user name isn't needed.

← *logBufP*

Pointer to a string buffer into which the sync log text, null-terminated, is stored. Supply NULL for this parameter if the log text isn't needed. If you supply a valid pointer for this parameter, you must specify the preallocated buffer length using the *logLenP* parameter; the returned log text will be truncated, if necessary, to fit within the buffer.

↔ *logLenP*

Pointer to the log buffer size. If *logBufP* is not NULL, on entry you must set this value to the size of the *logBufP* buffer. When this function returns, this value indicates the actual length of the log text, not counting the null terminator.

**Returns** Returns `errNone` if no error, or `dlkErrMemory` if the Desktop Link preferences resource couldn't be locked.

**Comments** The state information returned through *syncStateP* has one of the values defined by the `DlkSyncStateType` enum:

**Prototype**

```
typedef enum DlkSyncStateType {  
    dlkSyncStateNeverSynced = 0,  
    dlkSyncStateInProgress,  
    dlkSyncStateLostConnection,  
    dlkSyncStateLocalCan,  
    dlkSyncStateRemoteCan,  
    dlkSyncStateLowMemoryOnTD,  
    dlkSyncStateAborted,  
}
```

```

    dlkSyncStateCompleted,
    dlkSyncStateIncompatibleProducts,
    dlkSyncStateNPOD
} DlkSyncStateType;

```

| Value                            | Description                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| dlkSyncStateNeverSynced          | The handheld has never been synced.                                                                                                          |
| dlkSyncStateInProgress           | A sync is currently in progress.                                                                                                             |
| dlkSyncStateLostConnection       | The connection was lost during sync.                                                                                                         |
| dlkSyncStateLocalCan             | Sync was cancelled by the user on the handheld.                                                                                              |
| dlkSyncStateRemoteCan            | Sync was cancelled by the user from the desktop.                                                                                             |
| dlkSyncStateLowMemoryOnTD        | Sync ended due to a low memory condition on the handheld.                                                                                    |
| dlkSyncStateAborted              | Sync was aborted for some other reason.                                                                                                      |
| dlkSyncStateCompleted            | Sync completed normally.                                                                                                                     |
| dlkSyncStateIncompatibleProducts | Sync ended because the desktop HotSync product is incompatible with this version of the handheld HotSync.                                    |
| dlkSyncStateNPOD                 | The sync could not take place because the handheld has a 4.0-style password but the desktop hasn't yet been updated to a compatible version. |

## Miscellaneous System Functions

### *IntlGetRoutineAddress*

---

**Example** This function is most often used to obtain the handheld user name. The following code excerpt shows how to do this (for clarity, error-checking has been omitted):

---

```
MemHandle nameH;  
char *nameP;  
  
// Allocate a buffer for the user name  
nameH = MemHandleNew(dlkUserNameBufSize);  
nameP = MemHandleLock(nameH);  
  
// Obtain the user's name  
DlkGetSyncInfo(NULL, NULL, NULL, nameP, NULL, NULL);  
  
// ... Do something with the user name here ...  
  
// Now that we're done with the user name, free the buffer  
MemPtrUnlock(nameP);
```

---

**Compatibility** The `dlkSyncStateIncompatibleProducts` enum value was added in Palm OS 3.0. The `dlkSyncStateNPOD` enum value was added in Palm OS 4.0.

## IntlGetRoutineAddress Function

**Purpose** Return the address of an international manager or text manager function.

**Declared In** `IntlMgr.h`

**Prototype**  
`void *IntlGetRoutineAddress  
    (IntlSelector inSelector)`

**Parameters**  $\rightarrow$  *inSelector*  
One of the routine selectors defined in `IntlMgr.h`.

**Returns** Returns the address of the corresponding function. Returns `NULL` if an invalid routine selector is passed.

**Comments** Use this function for performance reasons. It returns the address of an international manager or text manager function. You can then use this address to call the function without having to go through the international manager's trap dispatch table. This function is mostly useful for optimizing the performance of text manager routines that are called in a tight loop.

You might also use this function to check for the presence of newer international manager and text manager functions. If the result is NULL, the function is not implemented on this device.

**Compatibility** Implemented only if [International Feature Set](#) is present.

**See Also** [IntlSetRoutineAddress\(\)](#), [SysGetTrapAddress\(\)](#)

## IntlSetRoutineAddress Function

**Purpose** Set the address of the function corresponding to an international manager or text manager function.

**Declared In** IntlMgr.h

**Prototype** `Err IntlSetRoutineAddress (IntlSelector iSelector,  
void *iProcPtr)`

**Parameters**

- *iSelector*  
One of the routine selectors defined in IntlMgr.h.
- *iProcPtr*  
Pointer to a function that the routine identified by *iSelector* should point to.

**Returns** Returns `errNone` if no error, or `intlErrInvalidSelector` if *iSelector* does not refer to a valid international manager or text manager routine.

**Comments** This function is useful for patching an international or text manager function. Normally only a locale module would need to patch one of these functions.

---

**WARNING!** If your application patches an international manager function using this function, you **must** remove the patch before your application exits. Do **not** use this mechanism to permanently patch international manager functions as it may cause unpredictable results for the system and other applications.

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present. If [5.0 New Feature Set](#) is present this function is unimplemented.

**See Also** [IntlGetRoutineAddress\(\)](#), [SysSetTrapAddress\(\)](#)

## Miscellaneous System Functions

### *LocGetNumberSeparators*

---

#### LocGetNumberSeparators Function

|                      |                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Get localized number separators.                                                                                                                                                                                                                                    |
| <b>Declared In</b>   | <code>Localize.h</code>                                                                                                                                                                                                                                             |
| <b>Prototype</b>     | <pre>void LocGetNumberSeparators     (NumberFormatType numberFormat,      Char *thousandSeparator,      Char *decimalSeparator)</pre>                                                                                                                               |
| <b>Parameters</b>    | <p>→ <i>numberFormat</i><br/>The format to use (see <a href="#">NumberFormatType</a>).</p> <p>← <i>thousandSeparator</i><br/>The character used for the thousands separator.</p> <p>← <i>decimalSeparator</i><br/>The character used for the decimal separator.</p> |
| <b>Returns</b>       | Returns nothing.                                                                                                                                                                                                                                                    |
| <b>Comments</b>      | The format to use is stored in the system preferences. You can obtain it by passing <code>prefNumberFormat</code> to <a href="#">PrefGetPreference()</a> .                                                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                                 |
| <b>See Also</b>      | <a href="#">StrLocalizeNumber()</a> , <a href="#">StrDelocalizeNumber()</a> , “ <a href="#">Localized Applications</a> ” in the <i>Palm OS Programmer’s Companion</i> , vol. I                                                                                      |

#### PceNativeCall Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Call a native ARM or Windows NT function from code running in the PACE (68k) environment.                                                                                                                                                                                                                                                                                                                     |
| <b>Declared In</b> | <code>PceNativeCall.h</code>                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>   | <pre>UInt32 PceNativeCall(NativeFuncType *nativeFuncP,                      void *userDataP)</pre>                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p>→ <i>nativeFuncP</i><br/>On a handheld with an ARM processor, this is a pointer to the ARM function to be executed. On Palm OS Simulator, this is a pointer to the name of a DLL and the name of the entry point within that DLL that is to be executed, separated by a null character and terminated with a null character. See the Comments, below, for more details on the format of this argument.</p> |

↔ *userDataP*

Pointer to an application-specific block of data that is passed to the ARM function. This block has no specific alignment requirements; it needn't be aligned on a 16- or 32-bit boundary. Note that your ARM function may impose specific alignment requirements, however.

**Returns** The return value of the specified ARM function is returned by *PceNativeCall*. This value is placed in both the A0 and D0 registers in the emulated 68k CPU, allowing *PceNativeCall* to support both pointer and immediate return value conventions.

**Comments** Applications that employ *PceNativeCall* won't work on handhelds running a version of Palm OS prior to Palm OS 5. Before calling *PceNativeCall*, your application must verify the underlying processor type, since the calling convention is different on Palm OS Simulator. See "[Calling an ARM Function](#)" on page 347 of *Palm OS Programmer's Companion*, vol. I for more information and an example.

*PceNativeCall* byte-swaps the parameter pointer and return value as appropriate for the Dragonball-to-ARM transition. This allows you to dereference *userDataP* directly from your ARM code. Because the operating system has no knowledge of the structure of the parameter block, however, it performs no byte-swapping within this block. Your ARM code must do this as necessary for your application (see "[Accessing 68K Data From an ARM Function](#)" on page 349 of the *Palm OS Programmer's Companion*, vol. I for more information).

On Palm OS Simulator, rather than passing a pointer to a block of ARM code in *nativeFuncP*, you instead pass a pointer to the name of a DLL and the name of the function within that DLL that is to be executed. These two names must be separated by a null character, and the entire sequence must be terminated by a null character. For example, to load the DLL found at

C:\TEST\_DLL\Debug\Simple.dll and call the function *TestNativeCall* within that DLL, you might pass a pointer to the following character string literal:

"C:\\TEST\_DLL\\Debug\\Simple.dll\\0TestNativeCall"

Note that if you don't supply an absolute path, Simulator looks for the DLL in (or relative to) the directory from which *PalmSim.exe*

## Miscellaneous System Functions

### *PceNativeCall*

---

is running. Thus, if the DLL is located in the same directory as `PalmSim.exe`, you can call the above function with:

```
"Simple.dll\0TestNativeCall"
```

On release ROMs, `PceNativeCall` fails silently if `nativeFuncP` is `NULL`. On debug ROMs, it generates an error. All other pointers are treated as valid code and followed. If `nativeFuncP` is invalid, the processor will try to execute the code anyway and will eventually generate an error.

---

**NOTE:** The call to your native function is guaranteed to be made from ARM mode.

---

For more information on how the ARM code should be structured and how to call back and forth between the PACE and ARM environments, see “[ARM-Native Functions](#)” on page 346 of the *Palm OS Programmer’s Companion*, vol. I.

**Compatibility**    Implemented only if [5.0 New Feature Set](#) is present.

# **Communications**

# Connection Manager

---

The Connection Manager allows other applications to access, add, and delete connection profiles contained in the Connection panel.

This chapter provides reference material for the Connection Manager API declared in the header file `ConnectionMgr.h`:

- [Connection Manager Constants](#)
- [Connection Manager Functions](#)

For more information on the Connection Manager, see the chapter “[Serial Communication](#)” on page 89 in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Connection Manager Data Types

### CncProfileID Typedef

|                      |                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | The <code>CncProfileID</code> type uniquely identifies a connection profile within the Connection Manager profile database. You pass this ID as a parameter to several of the Connection Manager functions. You can obtain a connection’s profile ID using <a href="#">CncProfileGetIDFromName()</a> or <a href="#">CncProfileGetIDFromIndex()</a> . |
| <b>Prototype</b>     | <code>typedef UInt32 CncProfileID</code>                                                                                                                                                                                                                                                                                                             |
| <b>Compatibility</b> | Defined only if <a href="#">Connection Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                           |

## Connection Manager Constants

### Profile Parameter Constants

The Connection Manager defines the following constants to represent individual parameters in the preinstalled connection profiles. Not all parameters work for all types of profiles.

| Parameter Name                            | Parameter Type      | Description                                                                                                                                                                                                                       |
|-------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kCncParamBaud</code>                | <code>UInt32</code> | The baud rate to use for the connection.                                                                                                                                                                                          |
| <code>kCncParamBluetoothDeviceAddr</code> | <code>buffer</code> | The 48-bit address ( <code>BD_ADDR</code> ) of the device that the handheld is connected to through the Bluetooth port. This parameter is only valid if <code>kCncParamPort</code> specifies the Bluetooth port.                  |
| <code>kCncParamBluetoothDeviceName</code> | <code>string</code> | The name of the device that the handheld is connected to through the Bluetooth port. The device name uses the UTF-8 character encoding. This parameter is only valid if <code>kCncParamPort</code> specifies the Bluetooth port.  |
| <code>kCncParamCountryIndex</code>        | <code>UInt16</code> | The index into the list of strings returned by <code>kCncParamIntlModemCountryStringList</code> and <code>kCncParamIntlModemResetStringList</code> that provides the name of the country and the reset commands for this profile. |

| Parameter Name       | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamDeviceKind  | UInt16         | The type of connection being made (general serial connection, connection to a modem, connection to a phone, and so on). This value is one of the <a href="#">Device Kind Constants</a> .                                                                                                                                                                                 |
| kCncParamDialingMode | UInt8          | For modem profiles, the dialing mode. 1 for Pulse dialing, 0 for TouchTone.                                                                                                                                                                                                                                                                                              |
| kCncParamFlowControl | UInt16         | The flow control setting (hardware handshaking). 0 indicates that the flow control setting is enabled and disabled depending on the baud rate. If you choose this setting, flow control is on if the baud rate is greater than 2400. 1 indicates that flow control is always on, and 2 indicates that it is always off. This parameter does not apply to phone profiles. |
| kCncParamInitString  | string         | For modem and phone profiles, a null-terminated string containing the commands sent to initialize the connection. The Connection panel removes any carriage returns or other control characters from the initialization string before saving it to the profile.                                                                                                          |

### Profile Parameter Constants

---

| Parameter Name                      | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamIntlModemCountryStringList | buffer         | <p>For modem profiles, a data buffer containing a list of possible countries. This list contains the countries in which the modem can operate and is shown in the Connection panel Details form for this profile. The selected country controls the dialing prefix and the modem reset string. The kCncParamCountryIndex parameter specifies the country selected from this list.</p> <p>The data buffer contains a packed block of null-terminated strings, each containing a country name. The first 16 bits of the data buffer (a UInt16 value) tells how many strings are contained in the block. You can use <a href="#">SysFormPointerArrayToStrings()</a> to convert the data buffer into an array of strings.</p> <p>Because this parameter value has a variable size, you must first call <a href="#">CncProfileSettingGet()</a> with a NULL data pointer to obtain the correct size.</p> |
| kCncParamIntlModemResetStringList   | buffer         | <p>For modem profiles, a data buffer containing possible reset strings. The kCncParamCountryIndex parameter specifies which reset string from this list is to be used. The actual string used is itself stored in the kCncParamResetString parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Parameter Name                  | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                | <p>The data buffer contains a packed block of null-terminated strings, each containing a reset string. The first 16 bits of the data buffer (a <code>UInt16</code> value) tells how many strings are contained in the block. You can use <a href="#"><code>SysFormPointerArrayToStrings()</code></a> to convert the data buffer into an array of strings.</p> <p>Because this parameter value has a variable size, you must first call <a href="#"><code>CncProfileSettingGet()</code></a> with a <code>NULL</code> data pointer to obtain the correct size.</p> |
| <code>kCncParamInvisible</code> | system flag    | If <code>true</code> , the profile is hidden from the user. If <code>false</code> , the profile is visible. This parameter is not currently used.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>kCncParamLocked</code>    | system flag    | If <code>true</code> , the profile is locked so that the user cannot edit it. If <code>false</code> , the profile can be edited. This parameter can be set by profiles, such as phone profiles, created by third party utilities.                                                                                                                                                                                                                                                                                                                                |
| <code>kCncParamName</code>      | string         | The name of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>kCncParamNoDetails</code> | system flag    | If <code>true</code> , the profile details should not be displayed. If <code>false</code> , they can be displayed. The profile details are the parameters that appear in the Details form of the Connection panel.                                                                                                                                                                                                                                                                                                                                               |

## Connection Manager

### Profile Parameter Constants

---

| Parameter Name                | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamNonEditable          | system flag    | <p>If <code>true</code>, the Connection panel's Edit form should be suppressed for this profile. If <code>false</code>, the Edit form can be displayed.</p> <p>This parameter differs from <code>kCncParamLocked</code> and <code>kCncParamReadOnly</code> in that it causes an alert to be displayed if the user taps the Edit button. The other parameters allow the Edit form to be displayed but do not allow changes to be made. Also, a non-editable profile can be deleted, but a read-only or locked profile cannot.</p> |
| kCncParamPort                 | UInt32         | The logical, physical, or virtual port identifier. See " <a href="#">Port Constants</a> " on <a href="#">page 1487</a> in the " <a href="#">Serial Manager</a> " chapter for more information.                                                                                                                                                                                                                                                                                                                                   |
| kCncParam_PSDCreator          | UInt32         | For phone profiles, the creator ID of the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| kCncParam_PSDName             | string         | For phone profiles, the name of the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| kCncParam_PSDParameter Buffer | buffer         | For phone profiles, a data buffer containing any necessary data that the phone driver needs to store. This parameter typically holds data that is set using the Details form of the Connection panel.                                                                                                                                                                                                                                                                                                                            |
| kCncParam_PSDType             | UInt32         | For phone profiles, the database type for the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter Name           | Parameter Type | Description                                                                                                                                                                                                                                             |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamReadOnly        | system flag    | If <code>true</code> , the profile is read-only and cannot be edited. If <code>false</code> , the profile can be edited. This parameter is only intended to be used by profiles pre-installed in the Palm OS.                                           |
| kCncParamReceiveTimeOut  | UInt32         | For phone profiles, the number of milliseconds to wait for a response from the phone. This time-out value is used by telephony functions that don't need to access the network (for example, the function <a href="#">TelNwkGetSelectedNetwork()</a> ). |
| kCncParamResetString     | string         | For modem and phone profiles, the reset string. For modem profiles, this is one of the strings in <code>kCncParamIntlModemResetStringList</code> .                                                                                                      |
| kCncParamSerialPortFlags | UInt32         | For phone profiles, bit flags that correspond to various serial port hardware settings. See “ <a href="#">Serial Settings Constants</a> ” on page 1490 for more information.                                                                            |
| kCncParamSystemFlags     | UInt32         | A bit flag representing all system flags. Currently, only bits 0 through 4 have a meaning. These correspond to the read-only bit, the invisible bit, the noneditable bit, the no details bit, and the locked bit, respectively.                         |
| kCncParamTimeOut         | UInt32         | The amount of time in milliseconds to wait for a response when CTS is unasserted and hardware flow control is on.                                                                                                                                       |

## Connection Manager

### Profile Parameter Size Constants

| Parameter Name     | Parameter Type | Description                                                                                                                       |
|--------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| kCncParamTTCreator | UInt32         | For phone profiles, the creator ID of the telephony task used by the phone driver.                                                |
| kCncParamTTType    | UInt32         | For phone profiles, the database type for the telephony task used by the phone driver.                                            |
| kCncParamVersion   | UInt8          | The version of the Connection Manager API under which this profile was created. The current version number is kCncProfileVersion. |
| kCncParamVolume    | UInt16         | For modem profiles, the modem volume.                                                                                             |

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Profile Parameter Size Constants

The size constants specify the size of each of the predefined parameters described in “[Profile Parameter Constants](#).” The following table lists the parameter name, the size of its value, and the size constant that gives this size. These size constants are suitable for passing to [CncProfileSettingGet\(\)](#) and [CncProfileSettingSet\(\)](#).

| Profile Parameter Name       | Size | Size Constant                       |
|------------------------------|------|-------------------------------------|
| kCncParamBaud                | 32   | kCncParamBaudSize                   |
| kCncParamBluetoothDeviceAddr | 8    | kCncParamBluetoothDeviceAddrSize    |
| kCncParamBluetoothDeviceName | 249  | kCncParamBluetoothDeviceNameMaxSize |
| kCncParamCountryIndex        | 16   | kCncParamCountryIndexSize           |

## Connection Manager

### *Profile Parameter Size Constants*

---

| Profile Parameter Name  | Size | Size Constant                     |
|-------------------------|------|-----------------------------------|
| kCncParamDeviceKind     | 16   | kCncParamDeviceKindSize           |
| kCncParamDialingMode    | 8    | kCncParamDialingModeSize          |
| kCncParamFlowControl    | 16   | kCncParamFlowControlSize          |
| kCncParamInitString     | 81   | kCncParamInitStringMaxSize        |
|                         | 81   | kCncProfileUsualInitStringsSize   |
| kCncParamInvisible      | 8    | kCncParamInvisibleSize            |
| kCncParamLocked         | 8    | kCncParamLockedSize               |
| kCncParamName           | 22   | kCncParamNameMaxSize              |
|                         | 22   | kCncProfileNameSize               |
| kCncParamNoDetails      | 8    | kCncParamNoDetailsSize            |
| kCncParamNonEditable    | 8    | kCncParamNonEditableSize          |
| kCncParamPort           | 32   | kCncParamPortSize                 |
| kCncParam_PSDCreator    | 32   | kCncParam_PSDCreatorSize          |
| kCncParam_PSDName       | 32   | kCncParam_PSDNameSize             |
| kCncParam_PSDType       | 32   | kCncParam_PSDTypeSize             |
| kCncParamReadOnly       | 8    | kCncParamReadOnlySize             |
| kCncParamReceiveTimeOut | 32   | kCncParamReceiveTimeOutSize       |
| kCncParamResetString    | 81   | kCncParamResetStringMaxSize       |
|                         | 8    | kCncProfileClassicResetStringSize |
|                         | 81   | kCncProfileUsualResetStringSize   |
| kCncParamSystemFlags    | 32   | kCncParamSystemFlagsSize          |
| kCncParamTimeOut        | 32   | kCncParamTimeOutSize              |

## Connection Manager

### *Profile Parameter Size Constants*

---

| Profile Parameter Name  | Size | Size Constant                         |
|-------------------------|------|---------------------------------------|
| kCncParamDeviceKind     | 16   | kCncParamDeviceKindSize               |
| kCncParamDialingMode    | 8    | kCncParamDialingModeSize              |
| kCncParamFlowControl    | 16   | kCncParamFlowControlSize              |
| kCncParamInitString     | 81   | kCncParamInitStringMaxSize            |
|                         | 81   | kCncProfileUsualInitStrings<br>ize    |
| kCncParamInvisible      | 8    | kCncParamInvisibleSize                |
| kCncParamLocked         | 8    | kCncParamLockedSize                   |
| kCncParamName           | 22   | kCncParamNameMaxSize                  |
|                         | 22   | kCncProfileNameSize                   |
| kCncParamNoDetails      | 8    | kCncParamNoDetailsSize                |
| kCncParamNonEditable    | 8    | kCncParamNonEditableSize              |
| kCncParamPort           | 32   | kCncParamPortSize                     |
| kCncParam_PSDCreator    | 32   | kCncParam_PSDCreatorSize              |
| kCncParam_PSDName       | 32   | kCncParam_PSDNameSize                 |
| kCncParam_PSDType       | 32   | kCncParam_PSDTypeSize                 |
| kCncParamReadOnly       | 8    | kCncParamReadOnlySize                 |
| kCncParamReceiveTimeOut | 32   | kCncParamReceiveTimeOutSize           |
| kCncParamResetString    | 81   | kCncParamResetStringMaxSize           |
|                         | 8    | kCncProfileClassicResetStri<br>ngSize |
|                         | 81   | kCncProfileUsualResetString<br>Size   |
| kCncParamSystemFlags    | 32   | kCncParamSystemFlagsSize              |
| kCncParamTimeOut        | 32   | kCncParamTimeOutSize                  |

| Profile Parameter Name | Size | Size Constant          |
|------------------------|------|------------------------|
| kCncParamTTCreator     | 32   | kCncParamTTCreatorSize |
| kCncParamTTType        | 32   | kCncParamTTTypeSize    |
| kCncParamVersion       | 8    | kCncParamVersionSize   |
| kCncParamVolume        | 16   | kCncParamVolumeSize    |

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Device Kind Constants

The device kind constants specify the type of connection being made. You specify the type of connection by defining a value for the kCncParamDeviceKind parameter using [CncProfileSettingSet\(\)](#).

| Constant                   | Value | Description                                |
|----------------------------|-------|--------------------------------------------|
| kCncDeviceKindSerial       | 0     | The connection is through the serial port. |
| kCncDeviceKindModem        | 1     | The connection is to a modem.              |
| kCncDeviceKindPhone        | 2     | The connection is to a phone.              |
| kCncDeviceKindLocalNetwork | 3     | The connection is to a LAN.                |

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Profile Parameter Types

The parameter type constants specify the type of value stored for a parameter in a connection profile. If you define a new parameter using [CncDefineParamID\(\)](#), you must use one of these constants to specify the type of data the parameter stores. The macro [CncGetParamType\(\)](#) can return this information for any parameter in the profile.

## Connection Manager

### Connection Manager Functions

---

| Constant            | Value | Description                                                                                                                                                                                                                                                                |
|---------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamSystemFlag | 0x00  | A system flag parameter. The Connection Manager can store up to 32 system flags. Flags are stored in a single bit and returned as a UInt8 value. The entire system flags word can be returned if you pass kCncParamSystemFlags to <a href="#">CncProfileSettingGet()</a> . |
| kCncParamUInt8      | 0x01  | A UInt8 parameter.                                                                                                                                                                                                                                                         |
| kCncParamUInt16     | 0x02  | A UInt16 parameter.                                                                                                                                                                                                                                                        |
| kCncParamUInt32     | 0x03  | A UInt32 parameter.                                                                                                                                                                                                                                                        |
| kCncParamString     | 0x04  | A string parameter.                                                                                                                                                                                                                                                        |
| kCncParamBuffer     | 0x05  | A generic block of data.                                                                                                                                                                                                                                                   |

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Connection Manager Functions

### CncAddProfile Function

**Purpose** Adds a profile to the Connection Manager.

**Declared In** ConnectionMgr.h

**Prototype**

```
Err CncAddProfile (Char *name, UInt32 port,
                  UInt32 baud, UInt16 volume, UInt16 handShake,
                  const Char *initString,
                  const Char *resetString,
                  Boolean isModem, Boolean isPulse)
```

**Parameters** ↔ *name*  
Pointer to the profile name to be added. If the name is already taken in the Connection panel then a duplication number is appended to it. The name added is returned here.

→ *port*

The port identification used by the profile. See “[Specifying the Port](#)” on page 100 of the *Palm OS Programmer’s Companion*, vol. II, *Communications* for more information.

→ *baud*

The baud rate used by the profile.

→ *volume*

The volume setting for the device (for Modem only).

→ *handShake*

Flow control setting (hardware handshaking). 0 specifies automatic (on at speeds > 2400 baud), 1 specifies always on, and 2 specifies always off.

→ *initString*

Pointer to the initialization string used by a modem (for Modem only).

→ *resetString*

Pointer to the reset string used by a modem (for Modem only).

→ *isModem*

true if Modem, false if Direct.

→ *isPulse*

true if Pulse dial, false if TouchTone.

**Returns**

`errNone`

No error.

`cncErrAddProfileFailed`

The add operation failed.

`cncErrProfileListFull`

The add operation failed because the profile list is full.

`cncErrConDBNotFound`

The connection database is missing.

**Comments**

All profiles within the Connection Manager must have a unique name. The Connection Manager tries to append a duplication number to the end of the name if you specify a name that is already taken.

## Connection Manager

### *CncDefineParamID*

---

There is a maximum limit to the number of profiles that can be maintained by the Connection Manager. If the limit is passed, an error is returned and that profile will not be added.

Profiles that do not need certain fields may pass NULL in the place of a value.

**Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present.

If [Connection Manager Feature Set](#) is present, use [CncProfileCreate\(\)](#) instead of using this function.

CncAddProfile is still supported for backward compatibility. In Palm OS 4.0 and higher, the maximum number of profiles that can be defined has greatly increased.

#### **Example**

```
AddMyProfile()
{
    Char *myConNameP;
    Err err;

    myConNameP = MemPtrNew(cncProfileNameSize);

    StrCopy(myConNameP, "Foobar");

    err = CncAddProfile(myConNameP, 'u328', 57600, 0, 0,
        "AT&FX4", 0, true, false);

    MemPtrFree(myConNameP);
}
```

## **CncDefineParamID Macro**

**Purpose** Creates and returns a parameter ID.

**Declared In** ConnectionMgr.h

**Prototype**

```
#define CncDefineParamID (parameterRange,
    parameterType,
    parameterID)
```

**Parameters** → *parameterRange*  
Use kCncParamThirdPartiesRange to specify that this parameter is not defined by the OS.

→ *parameterType*  
The type of value stored for the parameter. See “[Profile Parameter Types](#)” for a list of possible values.

→ *parameterID*

A unique value between 0 to 1023. The value must be unique within the profile for which you are defining the parameter.

If you are using a *parameterType* of *kCncParamSystemFlag*, specify a value from 0 to 31 to identify which of the system flag bit is to be set.

**Returns** Returns the parameter ID as a `UInt16` value.

**Comments** You use this macro only if you are defining your own connection profile and have a parameter that you need to define within that profile. The parameter ID immediately precedes its parameter value in the Connection Manager profile database. Because of how the database is formatted, the parameter ID must tell the Connection Manager how to interpret the next series of bytes. For this reason, the high order bits of the parameter ID include information about the type of value and whether the value is defined by the system or a third party.

**Compatibility** Parameter IDs of this format are only used if [4.0 New Feature Set](#) is present.

**See Also** [CncProfileSettingSet\(\)](#), [CncProfileSettingGet\(\)](#)

## CncDeleteProfile Function

**Purpose** Removes a profile from the Connection Manager.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncDeleteProfile (const Char *name)`

**Parameters** → *name*  
 Pointer to the name of the profile to be deleted.

**Returns** `errNone`  
 No error.

`cncErrProfileReadOnly`  
 The profile could not be deleted because it is read only.

`cncErrProfileNotFound`  
 The profile could not be found.

`cncErrConDBNotFound`  
 The connection database is missing.

## Connection Manager

### *CncGetParamType*

---

- Comments** The profiles that come preinstalled on the unit are read only and cannot be deleted.
- Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present. If [Connection Manager Feature Set](#) is present, use [CncProfileDelete\(\)](#) instead of using this function.

## CncGetParamType Macro

- Purpose** Returns the parameter type portion of the parameter ID.
- Declared In** `ConnectionMgr.h`
- Prototype**

```
#define CncGetParamType (parameterID)
```
- Parameters**  $\rightarrow$  *parameterID*  
A `UInt16` that contains the parameter ID.
- Returns** Returns a `UInt16` value where bits 11 through 14 contain one of the values in “[Profile Parameter Types](#)” and the other bits are clear.
- Compatibility** Parameter IDs of this format are only used if [4.0 New Feature Set](#) is present.
- See Also** [CncProfileSettingSet\(\)](#), [CncProfileSettingGet\(\)](#)

## CncGetProfileInfo Function

- Purpose** Returns the settings for a profile.
- Declared In** `ConnectionMgr.h`
- Prototype**

```
Err CncGetProfileInfo (Char *name, UInt32 *port,  
    UInt32 *baud, UInt16 *volume,  
    UInt16 *handShake,  
    Char *initString, Char *resetString,  
    Boolean *isModem, Boolean * isPulse)
```
- Parameters**  $\rightarrow$  *name*  
Pointer to the name of the profile to be returned. Passing in `NULL` causes this function to return the settings for the profile currently selected in the Connection panel.
- $\leftarrow$  *port*  
Pointer to the port identifier that the profile uses.

← *baud*  
Pointer to the baud rate that has been set for this profile.

← *volume*  
Pointer to the volume of the device (applies only to modems).

← *handShake*  
Pointer to the flow control setting (hardware handshaking). 0 indicates automatic (on at speeds > 2400 baud), 1 indicates always on, and 2 indicates always off.

← *initString*  
Pointer to the initialization string for the device (applies only to modems).

← *resetString*  
Pointer to the reset string for the device (applies only to modems).

← *isModem*  
Pointer to a Boolean value: `true` for Modem, `false` for Direct.

← *isPulse*  
Pointer to a Boolean value: `true` for Pulse dial, `false` for TouchTone.

**Returns**    `errNone`  
              No error.

`cncErrGetProfileFailed`  
              The get profile operation failed. The profile may or may not be there.

`cncErrProfileNotFound`  
              The profile could not be found

`cncErrConDBNotFound`  
              The connection database is missing.

**Comments**    One or more of the parameters may be set to `NULL` if that information is not desired.

**Compatibility**    Implemented only if [New Serial Manager Feature Set](#) is present. If [Connection Manager Feature Set](#) is present, use [CncProfileSettingGet\(\)](#) with one of the “[Profile Parameter Constants](#)” instead of using this function.

## Connection Manager

### *CncGetProfileList*

---

**Example**

```
{
    UInt32 portID, baud;
    UInt16 openPort;
    // get port id
    err = CncGetProfileInfo("Direct Serial", &portID, &baud,
        0, 0, 0, 0, 0, 0);
    if(!err)
    { // open the port
        SrmOpen(portID, baud, &openPort);
    }
}
```

## CncGetProfileList Function

**Purpose** Returns a list of available profiles that are available through the Connection Manager.

**Declared In** ConnectionMgr.h

**Prototype** Err CncGetProfileList (Char \*\*\*nameListPPP,  
UInt16 \*countP)

**Parameters**  $\leftarrow$  *nameListPPP*  
Pointer to a pointer to a list of profile names.  
 $\leftarrow$  *countP*  
Pointer to the number of profile names.

**Returns** *errNone*  
No error.  
*cncErrGetProfileListFailed*  
The profile list could not be found.  
*cncErrConDBNotFound*  
The connection database is missing.

**Comments** Allocation of the list is handled by the Connection Manager; deallocation is the responsibility of the calling application. Appended to the end of the list will be “-Current-”, which represents the profile currently selected in the Connection panel.

**Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present.

**Example**

```
//Declared globally
Char ** globalProfileList;
ListType *listP;
UInt16 globalProfileCount;
```

```
void SetConnectionList()
{
    //Get the list from the Connection Manager
    err = CncGetProfileList(&globalProfileList,
        &globalProfileCount);
    //Set the UI list
    LstSetListChoices(listP, globalProfileList,
        globalProfileCount);
}

void StopApplication()
{
    UInt16 i;

    //Deallocate the connection list
    For(i = 0; i < globalProfileCount; i++)
        MemPtrFree(globalProfileList[ i ]);
    MemPtrFree(globalProfileList);
}
```

## **CncGetSystemFlagBitnum Macro**

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns the number uniquely identifying a system flag parameter.                                         |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                          |
| <b>Prototype</b>     | #define CncGetSystemFlagBitnum (parameterID)                                                             |
| <b>Parameters</b>    | → <i>parameterID</i><br>The UInt16 containing the parameter ID.                                          |
| <b>Returns</b>       | Returns the ID of the system flag parameter, which is a value from 0 to 31.                              |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                          |

## Connection Manager

### *CncGetTrueParamID*

---

#### CncGetTrueParamID Macro

|                      |                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns the portion of the parameter ID that uniquely identifies the parameter.                                                        |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                        |
| <b>Prototype</b>     | <pre>#define CncGetTrueParamID (parameterID)</pre>                                                                                     |
| <b>Parameters</b>    | → <i>parameterID</i><br>A UInt16 containing the parameter ID.                                                                          |
| <b>Returns</b>       | Returns a UInt16 containing just the parameter ID. The high-order bits, which specify the parameter type and address space, are clear. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                               |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                                                        |

#### CncIsFixedLengthParamType Macro

|                      |                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Specifies whether the parameter value is fixed length or variable length.                                                |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                          |
| <b>Prototype</b>     | <pre>#define CncIsFixedLengthParamType (parameterID)</pre>                                                               |
| <b>Parameters</b>    | → <i>parameterID</i><br>A UInt16 containing the parameter ID.                                                            |
| <b>Returns</b>       | Returns true if the parameter is a fixed length parameter type such as UInt32, or false if it is a variable length type. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                 |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                                          |

## **CncIsSystemFlags Macro**

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns whether the parameter value is a system flag.                                                    |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                          |
| <b>Prototype</b>     | <code>#define CncIsSystemFlags (parameterID)</code>                                                      |
| <b>Parameters</b>    | <code>→ parameterID</code><br>The UInt16 containing the parameter ID.                                    |
| <b>Returns</b>       | Returns true if the parameter type is a system flag. Returns false otherwise.                            |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                          |

## **CncIsSystemRange Macro**

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Specifies whether the parameter is in the system range or in the third-party range.                      |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                          |
| <b>Prototype</b>     | <code>#define CncIsSystemRange (parameterID)</code>                                                      |
| <b>Parameters</b>    | <code>→ parameterID</code><br>A UInt16 containing the parameter ID.                                      |
| <b>Returns</b>       | Returns true if the parameter ID is defined by Palm OS, or false if it is defined by a third party.      |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                          |

## CncIsThirdPartiesRange Macro

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Specifies whether the parameter is defined by a third party.                                             |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                          |
| <b>Prototype</b>     | <pre>#define CncIsThirdPartiesRange (parameterID)</pre>                                                  |
| <b>Parameters</b>    | <p>→ <i>parameterID</i></p> <p>A UInt16 containing the parameter ID.</p>                                 |
| <b>Returns</b>       | Returns true if the parameter is a third-party parameter, or false if it is a system parameter.          |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                          |

## CncIsVariableLengthParamType Macro

|                      |                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns whether the parameter value is a variable-length type.                                                                     |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                    |
| <b>Prototype</b>     | <pre>#define CncIsVariableLengthParamType<br/>    (parameterID)</pre>                                                              |
| <b>Parameters</b>    | <p>→ <i>parameterID</i></p> <p>A UInt16 containing the parameter ID.</p>                                                           |
| <b>Returns</b>       | Returns true if the parameter is a variable-length string or a buffer or false if it holds a fixed-length type such as an integer. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                           |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet()</a> , <a href="#">CncProfileSettingGet()</a>                                                    |

## CncProfileCloseDB Function

|                    |                                                 |
|--------------------|-------------------------------------------------|
| <b>Purpose</b>     | Closes the Connection Manager profile database. |
| <b>Declared In</b> | ConnectionMgr.h                                 |
| <b>Prototype</b>   | <pre>Err CncProfileCloseDB (void)</pre>         |
| <b>Parameters</b>  | None.                                           |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Returns</b>       | <code>errNone</code><br>No error.<br><br><code>kCncErrDBAccessFailed</code><br>The database could not be closed or this is a reference counting error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>      | Use <a href="#">CncProfileOpenDB()</a> and <code>CncProfileCloseDB</code> as an optimization if you make several Connection Manager calls in succession. All Connection Manager calls open the profile database when they begin and close the database when they are finished. The Connection Manager maintains a reference count that tells it whether the database is open. If you call <code>CncProfileOpenDB</code> before making another Connection Manager call, the next call does not open or close the database. This saves your application the overhead of opening and closing the database each time a call is made. |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## CncProfileCount Function

|                      |                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns the number of connection profiles currently defined in the Connection Manager profile database.                  |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                                             |
| <b>Prototype</b>     | <code>Err CncProfileCount (UInt16 *profilesCountP)</code>                                                                |
| <b>Parameters</b>    | $\leftarrow profilesCountP$<br>The number of profiles.                                                                   |
| <b>Returns</b>       | <code>errNone</code><br>No error.<br><br><code>kCncErrDBAccessFailed</code><br>The profile database could not be opened. |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.                                           |
| <b>See Also</b>      | <a href="#">CncGetProfileList()</a>                                                                                      |

## CncProfileCreate Function

|                      |                                                                                                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Adds a profile record to the Connection Manager profile database.                                                                                                                                                                                                                                             |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>     | Err CncProfileCreate (CncProfileID *profileIdP)                                                                                                                                                                                                                                                               |
| <b>Parameters</b>    | $\leftarrow profileIdP$<br>Upon return, the unique ID of the new profile.                                                                                                                                                                                                                                     |
| <b>Returns</b>       | errNone<br>No error.<br><br>kCncErrDBAccessFailed<br>The profile database could not be opened.<br><br>a Data Manager error<br>The new record could not be created.                                                                                                                                            |
| <b>Comments</b>      | This function creates a new empty record in the Connection Manager profile database. To populate the profile, use <a href="#">CncProfileSettingSet()</a> to set parameter values, including the profile name. Use <a href="#">CncDefineParamID()</a> if you need to store information unique to your profile. |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.                                                                                                                                                                                                                                |
| <b>See Also</b>      | <a href="#">CncAddProfile()</a> , <a href="#">CncProfileDelete()</a>                                                                                                                                                                                                                                          |

## CncProfileDelete Function

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Deletes a profile.                                                                                                                 |
| <b>Declared In</b> | ConnectionMgr.h                                                                                                                    |
| <b>Prototype</b>   | Err CncProfileDelete (CncProfileID profileId)                                                                                      |
| <b>Parameters</b>  | profileId<br>The ID of the profile to delete.                                                                                      |
| <b>Returns</b>     | errNone<br>No error.<br><br>kCncErrDBAccessFailed<br>The profile database could not be opened, or the record could not be deleted. |

|                      |                                                                                      |
|----------------------|--------------------------------------------------------------------------------------|
|                      | kCncErrProfileParamNotFound                                                          |
|                      | The database does not contain a profile with the specified ID.                       |
| <b>Comments</b>      | The profiles that come preinstalled on the unit are read only and cannot be deleted. |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.       |
| <b>See Also</b>      | <a href="#">CncDeleteProfile()</a> , <a href="#">CncProfileCreate()</a>              |

## CncProfileGetCurrent Function

|                      |                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns the ID of the currently selected profile in the Connection panel.                                                                                                    |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                                                              |
| <b>Prototype</b>     | Err CncProfileGetCurrent<br>(CncProfileID *profileIdP)                                                                                                                       |
| <b>Parameters</b>    | ← <i>profileIdP</i><br>The ID of the current profile.                                                                                                                        |
| <b>Returns</b>       | errNone<br>No error.<br><br>kCncErrDBAccessFailed<br>The profile database could not be opened.                                                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.                                                                                               |
| <b>See Also</b>      | <a href="#">CncProfileGetIDFromIndex()</a> ,<br><a href="#">CncProfileGetIDFromName()</a> , <a href="#">CncProfileGetIndex()</a> ,<br><a href="#">CncProfileSetCurrent()</a> |

## CncProfileGetIDFromIndex Function

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Returns the profile ID given its index into the Connection Manager profile database. |
| <b>Declared In</b> | ConnectionMgr.h                                                                      |
| <b>Prototype</b>   | Err CncProfileGetIDFromIndex (UInt16 index,<br>CncProfileID *profileIdP)             |
| <b>Parameters</b>  | → <i>index</i><br>The index of the Connection Manager profile.                       |

## Connection Manager

### *CncProfileGetIDFromName*

---

|                      |                                                                                                                                                                                                       |

## CncProfileOpenDB Function

|                    |                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Opens the Connection Manager profile database.                                                                                                                                                                                                                        |
| <b>Declared In</b> | ConnectionMgr.h                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | Err CncProfileOpenDB (void)                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | None                                                                                                                                                                                                                                                                  |
| <b>Returns</b>     | <p>errNone<br/>No error.</p> <p>kCncErrDBAccessFailed<br/>The profile database could not be opened.</p>                                                                                                                                                               |
| <b>Comments</b>    | Use CncProfileOpenDB and <a href="#">CncProfileCloseDB()</a> as an optimization if you make several Connection Manager calls in succession. All Connection Manager calls open the profile database when they begin and close the database when they are finished. The |

## Connection Manager

### *CncProfileSetCurrent*

---

Connection Manager maintains a reference count that tells it whether the database is open. If you call `CncProfileOpenDB` before making another Connection Manager call, the next call does not open or close the database. This saves your application the overhead of opening and closing the database each time a call is made.

The Connection Manager profile database is created if it does not exist.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

## CncProfileSetCurrent Function

**Purpose** Sets the current profile.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileSetCurrent (CncProfileID profileId)`

**Parameters**  $\rightarrow$  *profileId*  
The ID of the profile to be made current.

**Returns** `errNone`  
No error.  
`kCncErrDBAccessFailed`  
The profile database could not be opened.

**Comments** The current profile is the profile that is used for the next network connection attempt.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncProfileGetCurrent\(\)](#)

## CncProfileSettingGet Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Obtains a value stored in one of the Connection Manager profiles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b> | ConnectionMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <pre>Err CncProfileSettingGet (CncProfileID profileId,<br/>                          UInt16 paramId, void *paramBufferP,<br/>                          UInt16 *ioParamSizeP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p>→ <i>profileId</i><br/>The ID of the profile from which to obtain a parameter value.</p> <p>→ <i>paramId</i><br/>The ID of the parameter to obtain. See “<a href="#">Profile Parameter Constants</a>” for a list of the parameters used in the profiles that come preinstalled on the device.</p> <p>← <i>paramBufferP</i><br/>A pointer to a buffer into which to write the parameter value. If the parameter stores a variable-sized value, you can determine the necessary size by passing NULL for paramBufferP. Upon return, paramSize contains the required size.</p> <p>↔ <i>ioParamSizeP</i><br/>On input, a pointer to the size of the buffer into which to write the parameter. On output, points to the number of bytes written to paramBufferP.</p> |
| <b>Returns</b>     | <p>errNone<br/>No error.</p> <p>kCncErrDBAccessFailed<br/>The profile database could not be opened.</p> <p>kCncErrProfileGetParamFailed<br/>The Connection Manager failed to obtain the value of the parameter.</p> <p>kCncErrProfileBadSystemFlagBitnum<br/>An attempt was made to obtain the value of a system flag that is undefined.</p> <p>kCncErrProfileBadParamSize<br/>The paramBufferP buffer is too small. ioParamSizeP contains the correct size for the buffer.</p>                                                                                                                                                                                                                                                                                    |

## Connection Manager

### *CncProfileSettingSet*

---

kCncErrProfileParamNotFound

The specified parameter is not defined in the profile.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncProfileSettingSet\(\)](#), [CncGetProfileInfo\(\)](#)

## CncProfileSettingSet Function

**Purpose** Sets a parameter value in the specified profile.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileSettingSet (CncProfileID iProfileId, UInt16 paramId, const void *paramBufferP, UInt16 paramSize)`

**Parameters**  $\rightarrow$  *iProfileId*  
The ID of the profile.

$\rightarrow$  *paramId*  
The ID of the parameter. See “[Profile Parameter Constants](#)” for a list of the parameters defined in the preinstalled connection profiles.

$\rightarrow$  *paramBufferP*  
A pointer to the value to set for this parameter.

$\rightarrow$  *paramSize*  
The size of the buffer passed in *paramBufferP*. See “[Profile Parameter Size Constants](#).”

**Returns** `errNone`  
No error.

`kCncErrDBAccessFailed`  
The profile database could not be opened.

`kCncErrProfileParamNotFound`  
No profile with the specified ID.

`kCncErrProfileSetParamFailed`  
The Connection Manager failed to set the value of the parameter.

kCncErrProfileBadParamSize

The paramBufferP buffer is too small. Most likely, the passed in size does not allow space for a string parameter's null terminator.

kCncErrProfileParamNameHasChange

An attempt was made to set the profile name to a name that is already used. The Connection Manager appends a duplication number to the end of the name and returns this error. You should use [CncProfileSettingGet\(\)](#) to find out the new name.

**Compatibility**      Implemented only if [Connection Manager Feature Set](#) is present.

**See Also**            [CncDefineParamID\(\)](#), [CncProfileSettingGet\(\)](#)

## Connection Manager

*CncProfileSettingSet*

---

# Exchange Manager

---

This chapter describes the Exchange Manager API declared in the header file `ExgMgr.h` and the Exchange Local Library API declared in the header file `ExgLocalLib.h`. It discusses the following topics:

- [Exchange Manager Data Structures](#)
- [Exchange Manager Constants](#)
- [Exchange Manager Functions](#)
- [Application-Defined Functions](#)

For more information on the Exchange Manager, see the chapter “[Object Exchange](#)” on page 1 of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Exchange Manager Data Structures

### ExgAskResultType Enum

**Purpose** The `ExgAskResultType` enum defines possible values for the `result` field of the [sysAppLaunchCmdExgAskUser](#) launch code parameter block.

**Prototype**

```
typedef enum {  
    exgAskDialog,  
    exgAskOk,  
    exgAskCancel }  
ExgAskResultType;
```

## Exchange Manager

### *ExgGoToType*

---

#### Value Descriptions

|                           |                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgAskDialog</code> | The Exchange Manager should display a dialog that prompts the user to confirm the receipt of data. See <a href="#">ExgDoDialog()</a> . |
| <code>exgAskOk</code>     | Accept the data.                                                                                                                       |
| <code>exgAskCancel</code> | Reject the data.                                                                                                                       |

#### ExgGoToType Struct

**Purpose** The `ExgGoToType` structure defines the `goToParams` field of the [ExgSocketType](#) structure. Applications that want to be launched after the data is received place their creator IDs in the `goToCreator` field and define the `goToParams` field. The values in this structure are copied to the [sysAppLaunchCmdGoto](#) launch code's parameter block.

**Prototype**

```
typedef struct {
    UInt16 dbCardNo;
    LocalID dbID;
    UInt16 recordNum;
    UInt32 uniqueID;
    UInt32 matchCustom;
} ExgGoToType;
```

#### Field Descriptions

|                          |                                                                     |
|--------------------------|---------------------------------------------------------------------|
| <code>dbCardNo</code>    | The card number of the database that contains the added record.     |
| <code>dbID</code>        | The local ID of the database that contains the added record.        |
| <code>recordNum</code>   | The index of the record that was added.                             |
| <code>uniqueID</code>    | The unique ID of the record that was added. This field is not used. |
| <code>matchCustom</code> | Application-specific information.                                   |

## ExgLocalSocketInfoType Struct

**Purpose** The ExgLocalSocketInfoType structure identifies information specific to the Local Exchange Library. The socketRef field of the [ExgSocketType](#) structure is set to this structure when you send and receive data using the Local Exchange Library. The Local Exchange Library creates this structure if it does not already exist. You only need to create it if you want to supply non-default values for the noAsk or previewInfoP fields.

**Prototype**

```
typedef struct {  
    Boolean freeOnDisconnect;  
    Boolean noAsk;  
    ExgPreviewInfoType *previewInfoP;  
    FileHand tempFileH;  
    Err err;  
    ExgLocalOpType op;  
} ExgLocalSocketInfoType;
```

### Field Descriptions

|                  |                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| freeOnDisconnect | Whether the structure is freed when the <a href="#">ExgDisconnect()</a> call is made. The default is true. In general, code that allocates a structure should be responsible for freeing that structure. Therefore, if you have allocated ExgLocalSocketInfoType, you should set this field to false and explicitly free the structure when you are finished with it. |
| noAsk            | Set to true to disable the display of the exchange dialog. If you want to, for example, create a vCalendar object and send it to the Datebook application in response to a user command, you probably want to set noAsk to true so that the user does not have to confirm the receipt of the data they just requested you to send.                                    |

## Exchange Manager

### *ExgPreviewInfoType*

---

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| previewInfoP | A pointer to an <a href="#">ExgPreviewInfoType</a> structure, used to display a preview of the data. If you wanted to simply use another application to help display data, you would create and initialize this structure.                                                                                                                                                                                                                                                                                                               |
| tempFileH    | A temporary buffer that the Local Exchange Library uses. Do not set this field directly; the Local Exchange Library should set it.                                                                                                                                                                                                                                                                                                                                                                                                       |
| err          | The error code returned from the Local Exchange Library. Do not set this field directly; the Local Exchange Library should set it.                                                                                                                                                                                                                                                                                                                                                                                                       |
| op           | <p>The operation in progress. Do not set this field directly. The Local Exchange Library sets this field to one of the following:</p> <p><code>exgLocalOpNone</code><br/>No operation in progress.</p> <p><code>exgLocalOpPut</code><br/>A send is in progress.</p> <p><code>exgLocalOpAccept</code><br/>A receive is in progress.</p> <p><code>exgLocalOpGet</code><br/>A get is in progress.</p> <p><code>exgLocalOpGetSender</code><br/>The library is receiving information from the sending application during a get operation.</p> |

## ExgPreviewInfoType Struct

**Purpose** The `ExgPreviewInfoType` structure provides information to the [ExgNotifyPreview\(\)](#) function. The `ExgNotifyPreview` function uses this information to have the application display a preview of the data to be received in the exchange dialog.

**Prototype** `typedef struct {`

```
    UInt16      version;  
    ExgSocketType *socketP;  
    UInt16      op;  
    Char        *string;  
    UInt32      size;  
    RectangleType bounds;  
    UInt16      types;  
    Err         error;  
} ExgPreviewInfoType;
```

### Field Descriptions

- *version* Set this field to 0 to specify version 0 of this structure.
- *socketP* A pointer to the socket structure (see [ExgSocketType](#)). The `libraryRef` field must identify the exchange library from which preview data should be received, and the `target`, `type`, or `name` field should be defined as well.
- *op* One of the following constants:
- `exgPreviewDialog`  
Display a modal dialog containing the preview. This constant is only used in situations where one application launches another to display data.
  - `exgPreviewDraw`  
The preview is a graphic.
  - `exgPreviewLongString`  
The preview is a long string.
  - `exgPreviewQuery`  
Ask the application which preview operations it supports. The answer is returned in the `types` field. If the application does not support any preview modes, the error field contains `exgErrNotSupported`.
  - `exgPreviewShortString`  
The preview is a short string.

## Exchange Manager

### *ExgSocketType*

---

|                 |                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| ← <i>string</i> | A buffer into which the application places the string preview if <code>exgPreviewLongString</code> or <code>exgPreviewShortString</code> is specified. |
| → <i>size</i>   | The allocated size of the string field.                                                                                                                |
| → <i>bounds</i> | The bounds of the rectangle in which the application draws the graphic if <code>exgPreviewDraw</code> is specified.                                    |
| ← <i>types</i>  | Upon return from an <code>exgPreviewQuery</code> operation, a bit field identifying the types of previews the application supports.                    |
| ← <i>error</i>  | The error code returned from the application. If <code>errNone</code> , the preview operation was successful.                                          |

Applications can define and use their own constants for the preview operation. Operations specific to an application are numbered starting at `exgPreviewFirstUser` and should be no greater than `exgPreviewLastUser`.

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## ExgSocketType Struct

**Purpose** The `ExgSocketType` structure defines an Exchange Manager socket, which is passed to most Exchange Manager functions. The `ExgSocketPtr` type points to a `ExgSocketType` structure.

**Prototype**

```
typedef struct ExgSocketType {
    UInt16 libraryRef;
    UInt32 socketRef;
    UInt32 target;
    UInt32 count;
    UInt32 length;
    UInt32 time;
    UInt32 appData;
    UInt32 goToCreator;
    ExgGoToType goToParams;
    UInt16 localMode:1;
    UInt16 packetMode:1;
    UInt16 noGoTo:1;
```

```
    UInt16 noStatus:1;
    UInt16 preview:1;
    UInt16 reserved:11;
    Char *description;
    Char *type;
    Char *name;
} ExgSocketType;
```

```
typedef ExgSocketType* ExgSocketPtr;
```

Note that when data is received, some of the fields in this structure may not have values. When you are sending data, it is recommended that you provide values for all of these fields, but you should not rely on receiving values for the fields marked optional.

### Field Descriptions

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>libraryRef</code> | <p>The exchange library in use. When an application or library receives a socket, this field is already assigned.</p> <p>When sending data, applications may identify the exchange library they want to connect with by providing a URL in the <code>name</code> field. If so, they should use 0 for the <code>libraryRef</code> field. The Exchange Manager then determines which library corresponds to the URL and assigns the <code>libraryRef</code> field. See the Comments in the <a href="#">ExgPut()</a> function description for more information.</p> |
| <code>socketRef</code>  | <p>The connection identifier. This value is supplied by the exchange library when a connection is established. It contains any necessary library-specific data.</p>                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>target</code>     | <p>The creator ID of the application that should receive the message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>count</code>      | <p>The number of objects in this connection, usually 1 (optional).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Exchange Manager

### *ExgSocketType*

---

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| length      | The total byte count for all objects being sent (optional).                                                                                                                                                                                                                                                                                                                                                                                              |
| time        | The last modified time of object (optional).                                                                                                                                                                                                                                                                                                                                                                                                             |
| appData     | Application-specific information (optional).                                                                                                                                                                                                                                                                                                                                                                                                             |
| goToCreator | The creator ID of the application to launch using the <a href="#">sysAppLaunchCmdGoto</a> launch code after the item is received if noGoTo is 0. The value is assigned by the application that receives the object. See the Comments section in <a href="#">ExgDisconnect()</a> for more information.                                                                                                                                                    |
| goToParams  | If goToCreator is specified, then this field contains data that is copied into the launch code's parameter block. See <a href="#">ExgGoToType</a> .                                                                                                                                                                                                                                                                                                      |
| localMode   | Set to 1 to exchange with local device only. A localMode of 1 is equivalent to specifying a URL with the <code>exgLocalPrefix</code> . Set to 0 to enable an exchange with a remote machine. The default is 0.                                                                                                                                                                                                                                           |
| packetMode  | Set to 1 to use connectionless packet mode (Ultra). The default is 0. Ultra mode is not currently supported.                                                                                                                                                                                                                                                                                                                                             |
| noGoTo      | Set to 1 to disable launching the application with <a href="#">sysAppLaunchCmdGoto</a> . The default is 0.                                                                                                                                                                                                                                                                                                                                               |
| noStatus    | <p>If <code>true</code>, the exchange library should not display a progress dialog. If <code>false</code>, the library can display a progress dialog. The default is <code>false</code>.</p> <p>The Exchange Manager sets and clears this bit at various times while data is received. Applications may also want to set this bit if they use the Local Exchange Library and want to prevent the progress dialog from being displayed during a send.</p> |

|             |                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| preview     | If true, a preview is in progress. The <a href="#">ExgNotifyPreview()</a> function sets this bit while the preview takes place and clears it when the preview is finished. Exchange libraries should not discard any data while a preview is in progress because the full data must be sent later if the receiving user accepts it. |
| reserved    | Reserved system flags.                                                                                                                                                                                                                                                                                                              |
| description | A pointer to the text description of the object (optional).                                                                                                                                                                                                                                                                         |
| type        | A pointer to the MIME type of the object (optional).                                                                                                                                                                                                                                                                                |
| name        | The name of the object being sent. This can be a URL whose scheme identifies the exchange library to connect with.<br><br>If the name has a colon, it is treated as a URL.                                                                                                                                                          |

**Compatibility** The noGoTo and noStatus flags are only defined if [3.5 New Feature Set](#) is present, and the noStatus flag has no effect unless [4.0 New Feature Set](#) is present. The preview flag is only defined if [4.0 New Feature Set](#) is present.

## Exchange Manager Constants

### Registry ID Constants

The registry ID constants are used in the Exchange Manager registry. Exchange libraries register for the URL prefixes they handle, and applications register for the types of data they receive. The registry ID constants specify which type of data is being registered for.

## Exchange Manager

### Predefined URL Schemes

---

| Constant                       | Value                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgRegCreatorID</code>   | <code>0xffffb</code> | Register for a creator ID. The <code>target</code> field of the <a href="#">ExgSocketType</a> contains the creator ID of the application that should receive the data. Typically, the application with the matching creator ID receives the data, but it is possible for one application to register for another's creator ID and receive data in its place.                                                                                      |
| <code>exgRegSchemeID</code>    | <code>0xffffc</code> | Register for a URL scheme. Typically, only exchange libraries register for URL schemes. Applications can register for URL schemes, but they only receive the URL when <a href="#">ExgRequest()</a> is called. If the <code>name</code> field of the <code>ExgSocketType</code> contains a colon (:), the portion of the URL before the colon is the URL scheme. The default library registered for URLs with that scheme will handle the message. |
| <code>exgRegExtensionID</code> | <code>0xffffd</code> | Register for a filename extension. If the <code>name</code> field of the <code>ExgSocketType</code> contains a period (.), the portion of the name after the last period is the filename extension. The application registered to handle files of that extension will handle the message.                                                                                                                                                         |
| <code>exgRegTypeID</code>      | <code>0xffffe</code> | Register for a MIME type. If the <code>type</code> field of the <code>ExgSocketType</code> contains a value, the application registered to receive that MIME type handles the message.                                                                                                                                                                                                                                                            |

**Compatibility** The `exgRegCreatorID` and `exgRegSchemeID` constants are only defined if [4.0 New Feature Set](#) is present.

## Predefined URL Schemes

The Exchange Manager provides these predefined URL schemes, for which exchange libraries can register.

| Constant       | Value    | Description                                                                                                                                                                                                    |
|----------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgBeamScheme  | "_beam"  | The URL scheme for Beam commands. By default, the IR Library handles this scheme.                                                                                                                              |
| exgSendScheme  | "_send"  | The URL scheme for Send commands. The purpose of the Send command is to provide a choice of transport mechanisms to the user; therefore, any exchange library that sends data should register for this scheme. |
| exgLocalScheme | "_local" | The URL scheme for the Local Exchange Library.                                                                                                                                                                 |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## Predefined URL Prefixes

The Exchange Manager provides the following prefixes, which can be used to construct URLs appropriate for the name field of the [ExgSocketType](#) structure. When sending data, applications provide a URL to identify the exchange library that should transport the data.

| Constant      | Value                   | Description                                                                                                                                                                                                                                          |
|---------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgBeamPrefix | (exgBeamScheme ":")     | The URL to beam data.                                                                                                                                                                                                                                |
| exgSendPrefix | ("?" exgSendScheme ":") | A URL for the general Send command. Because this URL begins with a question mark (?), the Exchange Manager displays a dialog with a list of exchange libraries registered for the exgSendScheme. The user then chooses the desired exchange library. |

## Exchange Manager

### Exchange Manager Functions

---

| Constant                       | Value                                                      | Description                                                                                                                                                                                           |
|--------------------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgSendBeamPrefix</code> | <code>("?" exgSendScheme ";"<br/>exgBeamScheme ":")</code> | A URL for the general Send command. The Exchange Manager displays a dialog with a list of exchange libraries registered for either the <code>exgSendScheme</code> or the <code>exgBeamScheme</code> . |
| <code>exgLocalPrefix</code>    | <code>(exgLocalScheme ":")</code>                          | The URL for using the Local Exchange Library.                                                                                                                                                         |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## Exchange Manager Functions

### ExgAccept Function

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |         |                               |                                        |                                 |                                                                                                                       |

| <code>exgErrNotSupported</code> | A preview is in progress, and the exchange library identified by <code>libraryRef</code> doesn't support preview mode                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |         |                               |                                        |                                 |                                                                                                                       |

**Comments** Applications call this function when launched with the [sysAppLaunchCmdExgReceiveData](#) or [sysAppLaunchCmdExgPreview](#) launch code. The launch code contains `socketP` in its parameter block. Applications should pass this socket to `ExgAccept` to accept the connection, then call [ExgReceive\(\)](#) one or more times to receive the data, and then call [ExgDisconnect\(\)](#) to disconnect.

---

**NOTE:** Don't create the socket on the receiving side of an exchange. The socket is passed to you in the command parameter block of the [sysAppLaunchCmdExgReceiveData](#) or [sysAppLaunchCmdExgPreview](#) launch code.

---

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present. Preview mode is supported only if [4.0 New Feature Set](#) is present.

**See Also** [ExgConnect\(\)](#), [ExgPut\(\)](#), [ExgGet\(\)](#)

## ExgConnect Function

## Exchange Manager

*ExgConnect*

---

|                                   |                                                                 |
|-----------------------------------|-----------------------------------------------------------------|
| <code>exgMemError</code>          | There isn't enough free memory to respond to the request        |
| <code>exgErrNotEnoughPower</code> | The battery does not have enough power to perform the operation |

Other error codes depend on the exchange library.

**Comments** Applications can call this function to initiate a connection for sending multiple objects or for performing two-way communications. Some exchange libraries support sending multiple objects but do not support this call. See “[Sending Multiple Objects](#)” on page 16 of *Palm OS Programmer's Companion*, vol. II, *Communications* for more information.

Before calling this function, the application must initialize the `socketP` parameter. The socket should identify the exchange library to connect with by providing either a library reference number in the `libraryRef` field or a URL in the `name` field. The default exchange library registered for that type of URL handles the connection.

To provide users with a choice of transport mechanisms, specify a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

For example, many applications on Palm OS® 4.0 or higher support a Send command. This command generates a URL with the prefix `exgSendPrefix` (see [Predefined URL Prefixes](#)). The Exchange Manager displays a dialog containing a list of libraries registered for that URL scheme. The user selects an exchange library, and that library's `ExgLibConnect` function is called.

If the library is not specified by either URL or library reference number (in the `libraryRef` field), the Exchange Manager by default uses the IR Library; however, if the `localMode` flag is set, the Local Exchange Library is used instead.

In addition to specifying the library, you can set the `count` field in `socketP` before making this call to indicate the number of objects that are going to be sent. Use a count of 0 if the number of objects isn't known in advance.

If no error is returned from `ExgConnect`, applications can follow this call either by sending multiple objects or requesting data from the remote device or both. To send an object, call `ExgPut()` at the beginning of each object and call `ExgSend()` one or more times per object to send the data. To request data from the remote device, use `ExgGet()` (and then use `ExgReceive()` to receive the requested data). You can use these calls in combination with each other to support two-way communications. After all of the objects have been sent and received, call `ExgDisconnect()` to disconnect.

---

**IMPORTANT:** Not all exchange libraries support the sending of multiple objects or using `ExgGet` to request data.

---

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present. `ExgConnect` was for system use only until the release of Palm OS 4.0. Multiple object sending and identifying exchange libraries by URL are supported only if [4.0 New Feature Set](#) is present. On earlier releases, this function is an alias for the `ExgPut` function.

## ExgControl Function

**Purpose**    Requests that an exchange library perform an operation.

**Declared In**    `ExgMgr.h`

**Prototype**    `Err ExgControl (ExgSocketType *socketP, UInt16 op, void *valueP, UInt16 *valueLenP)`

**Parameters**     $\rightarrow$  *socketP*  
A pointer to the socket structure (see [ExgSocketType](#)). Specify either a value for the `libraryRef` field or a URL in the `name` field. `libraryRef` should be 0 if the `name` field contains a URL.

$\rightarrow$  *op*  
A constant identifying the operation that the exchange library should perform. See the Comments section for more information.

## Exchange Manager

### *ExgControl*

---

↔ *valueP*

Upon entry, a parameter that the exchange library requires to perform the operation, if any. Most operations do not require an input parameter. Upon return, contains the result of the operation.

↔ *valueLenP*

The size of the *valueP* buffer. The size is updated upon return to show the actual length of the content returned.

**Returns** Returns one of the following error codes:

|                                 |                                                               |
|---------------------------------|---------------------------------------------------------------|
| <code>errNone</code>            | Success                                                       |
| <code>exgErrBadLibrary</code>   | Couldn't find the requested exchange library                  |
| <code>exgErrNotSupported</code> | The exchange library does not support the requested operation |

Other error codes depend on the exchange library.

**Comments** The Exchange Manager uses this function to request information from the exchange library. Applications may also call this function.

The Exchange Manager defines and uses a set of operation constants that it might send to any exchange library. These constants begin with the prefix `exgLibCtlGet`. The type of the variable pointed to by *valueP* depends on the type of operation to be performed. [Table 57.1](#) lists and describes the predefined Exchange Manager operations.

**Table 57.1 ExgControl operations for all exchange libraries**

| Operation<br>exgLibCtlGet... | value Data Type                                                           | Description                                                                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Preview                      | Boolean. Output only.                                                     | Returns <code>true</code> if the exchange library supports preview mode or <code>false</code> if not. If the exchange library does not respond to this operation, it is assumed to support preview mode.                                                                                                      |
| Title                        | String buffer of size <code>exgTitleBufferSize</code> bytes. Output only. | Returns the name of the exchange library as it should appear in the Send dialog. All exchange libraries must respond to this operation.                                                                                                                                                                       |
| Version                      | UInt16. Output only.                                                      | Returns the version of the exchange library API that this library implements. The constant <code>exgLibAPIVersion</code> defines the current version number. If the exchange library does not respond to this operation, the library supports the version of the Exchange Library API defined in Palm OS 4.0. |

An exchange library may also define its own operations. For example, the IR Library supports operations to enable or disable beaming, to set the baud rates, or to use the serial port (see “[IR Control Constants](#)” on page 1318). The SMS Library supports operations that allow you to set the SMS preferences for sending messages or to manipulate multipart messages (see “[SMS Control Constants](#)” on page 2138). Operations specific to an exchange library are numbered starting at `exgLibCtlSpecificOp`.

The `socketP` passed to this function must identify an exchange library either using the `libraryRef` field or using a URL in the `name` field. The Comments section in [ExgConnect \(\)](#) describes how an application should identify the exchange library.

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

## ExgDBRead Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts a Palm OS database from its internal format and writes it to storage RAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>Err ExgDBRead (ExgDBReadProcPtr readProcP,<br/>               ExgDBDeleteProcPtr deleteProcP,<br/>               void* userDataP, LocalID* dbIDP,<br/>               UInt16 cardNo, Boolean* needResetP,<br/>               Boolean keepDates)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <div><p>→ <i>readProcP</i><br/>A pointer to a function that reads in the database and passes it to <code>ExgDBRead</code>. See <a href="#">ExgDBReadProcPtr()</a> for details.</p><p>→ <i>deleteProcP</i><br/>A pointer to a function that is called if a database with an identical name already exists on the device. See <a href="#">ExgDBDeleteProcPtr()</a> for details.</p><p>→ <i>userDataP</i><br/>A pointer to any data you want to pass to either the <code>readProcP</code> or <code>deleteProcP</code> functions. Often, this parameter is used to pass the <a href="#">ExgSocketType</a> that is required by many Exchange Manager functions.</p><p>← <i>dbIDP</i><br/>The ID of the database that <code>ExgDBRead</code> created on the local device.</p><p>→ <i>cardNo</i><br/>The number of the card on which the database is to be stored.</p><p>← <i>needResetP</i><br/>Set to true by <code>ExgDBRead</code> if the <code>dmHdrAttrResetAfterInstall</code> attribute bit is set in the received database.</p><p>→ <i>keepDates</i><br/>Specify true to retain the creation, modification, and last backup dates as set in the received database header. Specify false to reset these dates to the current date.</p></div> |
| <b>Returns</b>     | Returns <code>errNone</code> if successful; otherwise, returns one of the data manager error codes ( <code>dmErr...</code> ) or a callback-specific error code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

(If the readProcP function returns an error, it is also returned by ExgDBRead.)

**Comments** This function converts data received from an exchange library or from any other transport mechanism into a Palm OS database and stores that database in the storage heap. It is not required that you use this function in conjunction with Exchange Manager calls. That is, it's possible to use this function to perform other operations, such as converting a database created on the desktop computer to a Palm OS formatted database in the storage heap.

The primary use of this function, however, is to receive a database that has been beamed onto the device. In this case, call ExgDBRead in response to the launch code

[sysAppLaunchCmdExgReceiveData](#) after calling [ExgAccept\(\)](#) to accept the connection. Place the call to [ExgReceive\(\)](#) in the read callback function you passed as the readProcP parameter. Pass the [ExgSocketType](#) structure returned from ExgAccept in the userDataP parameter so that you have access to it in the read callback function.

The read callback function performs the actual reading of data. ExgDBRead calls the read callback function multiple times. Each time, the sizeP parameter contains the number of bytes ExgDBRead expects the data returned in dataP to contain. It's important for the read callback function to set the number of bytes (in sizeP) that it actually placed in dataP if it's not the same as what ExgDBRead expected. ExgDBRead stops calling the read callback function after 0 is returned in sizeP.

The callback function you pass in deleteProcP handles the case where the database being read already exists on the device. It is called only in that circumstance. The callback function may want to close the database if it is open, change the existing database's name, or delete the existing database to allow an overwrite. See [ExgDBDeleteProcPtr\(\)](#) for more information.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

| <b>Purpose</b>     | Converts a given Palm OS database from its internal format on the local device and writes it using a function you supply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <pre>Err ExgDBWrite (ExgDBWriteProcPtr writeProcP,<br/>                void* userDataP, const char* nameP,<br/>                LocalID dbID, UInt16 cardNo)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p>→ <i>writeProcP</i><br/>A pointer to a function that writes out the database identified by <i>dbID</i>. See <a href="#">ExgDBWriteProcPtr()</a> for details.</p> <p>→ <i>userDataP</i><br/>A pointer to any data you want to pass to the <i>writeProcP</i> function. Often, this parameter is used to pass the <a href="#">ExgSocketType</a> that is required by many Exchange Manager functions.</p> <p>→ <i>nameP</i><br/>A pointer to the name of the database that you want <i>ExgDBWrite</i> to write. This database is passed to <i>writeProcP</i>.</p> <p>→ <i>dbID</i><br/>The ID of the database that you want <i>ExgDBWrite</i> to pass to <i>writeProcP</i>. If you don't supply an ID, then <i>nameP</i> is used to search for the database by name.</p> <p>→ <i>cardNo</i><br/>The number of the card on which to look for the database identified by <i>nameP</i>.</p> |
| <b>Returns</b>     | Returns <code>errNone</code> if successful; otherwise, returns one of the data manager error codes ( <code>dmErr...</code> ) or a callback-specific error code. (If the <i>writeProcP</i> function returns an error, it is also returned by <i>ExgDBWrite</i> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Comments</b>    | <p>This function converts a Palm OS formatted database on the storage heap into a stream of bytes that can be sent over the Internet or over any other transport mechanism. It is not required that you use this function in conjunction with Exchange Manager calls.</p> <p>The primary use of this function, however, is to write a database that is going to be beamed onto another device. In this case, call <i>ExgDBWrite</i> after establishing the connection with <a href="#">ExgPut()</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                |

Place the call to [ExgSend\(\)](#) in the write callback function you passed as the `writeProcP` parameter. Pass the [ExgSocketType](#) structure returned from `ExgSend` in the `userDataP` parameter so that you have access to it in the write callback function.

The write callback function performs the actual writing of data. `ExgDBWrite` calls the write callback function multiple times. Each time, the `sizeP` parameter contains the number of bytes of `dataP` that are to be written. If the write callback function didn't handle it all, it's important that it set in `sizeP` the number of bytes that it did handle successfully. `ExgDBWrite` stops calling the write callback function after 0 is returned in `sizeP`.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

**See Also**        [ExgDBRead\(\)](#)

## ExgDisconnect Function

**Purpose**            Terminates an Exchange Manager transfer and disconnects.

**Declared In**      `ExgMgr.h`

**Prototype**        `Err ExgDisconnect (ExgSocketType *socketP,  
                         Err error)`

**Parameters**       `→ socketP`

A pointer to the socket structure (see [ExgSocketType](#)) identifying the connection to terminate.

`→ error`

Any error that occurred. This parameter tells the exchange library why the connection is being broken. Normally the error code from [ExgSend\(\)](#) or [ExgReceive\(\)](#) is passed in here.

**Returns**           Returns one of the following error codes:

`errNone`                      Success

`exgErrBadLibrary`          Couldn't find default exchange library

`exgMemError`                Couldn't read data to send

`exgErrUserCancel`          User cancelled transfer

Other error codes depend on the exchange library.

## Exchange Manager

### *ExgDisconnect*

---

May display a fatal error message if `socketP` doesn't contain a `libraryRef` value.

**Comments** Applications must call this function when finished sending data or receiving data. It terminates the connection made with [ExgConnect\(\)](#), [ExgAccept\(\)](#), [ExgPut\(\)](#), or [ExgGet\(\)](#).

In the error parameter, pass any error that occurs during the application loop, including errors returned from other Exchange Manager functions. This ensures that the connection is shut down knowing that it failed rather than succeeded.

It's especially important to check the result code from this function, since this will tell you if the transfer was successful. An `errNone` return value means that the item was delivered to the destination successfully. It does not mean that the user on the other end actually kept the data.

`ExgDisconnect` is used after sending and receiving. When receiving, the application can insert its creator ID into the `goToCreator` field in the socket structure and add other goto information in the `goToParams` field. After the application returns from the [sysAppLaunchCmdExgReceiveData](#) launch code, the exchange library may call [ExgNotifyGoto\(\)](#), which launches the `goToCreator` application with the standard launch code [sysAppLaunchCmdGoto](#).

---

**IMPORTANT:** Placing your creator ID in the `goToCreator` field is no longer a guarantee that you receive this launch code starting in Palm OS 4.0 because Palm OS 4.0 supports the sending of multiple objects at once. Thus, another application might overwrite the `goToCreator` field after your application has disconnected, making that application the recipient of the launch code.

---

Note that some exchange libraries wait to establish a connection until `ExgDisconnect` is called. The IR Library, for example, buffers the data that it receives and then waits until `ExgDisconnect` to actually send this data unless `ExgConnect` is called to establish a multi-object send connection.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

Prior to Palm OS release 4.0, the Exchange Manager always launched the `goToCreator` application, if one was provided, upon return from this function. If [4.0 New Feature Set](#) is present, the Exchange Manager does not launch the `goToCreator` application. Exchange libraries that want the previous behavior must explicitly call `ExgNotifyGoto()`.

## ExgDoDialog Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Displays a dialog that allows users to accept or reject the receipt of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <pre>Boolean ExgDoDialog (ExgSocketType *socketP,<br/>                    ExgDialogInfoType *infoP, Err *errP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p>→ <i>socketP</i></p> <p>A pointer to the socket structure (see <a href="#">ExgSocketType</a>) identifying the connection. A value must be provided for the <code>libraryRef</code> field.</p> <p>Applications can obtain the socket structure from the <a href="#">sysAppLaunchCmdExgAskUser</a> launch code parameter block.</p> <p>↔ <i>infoP</i></p> <p>A pointer to an <code>ExgDialogInfoType</code> structure (see the Comments section below).</p> <p>← <i>errP</i></p> <p><code>errNone</code> if no error, or the error code if an error occurred. Currently, no errors are returned.</p> |
| <b>Returns</b>     | Returns <code>true</code> if the user clicks the OK button on the dialog, or <code>false</code> otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>    | <p>This function displays the exchange dialog, which prompts the user to accept or reject incoming data.</p> <p>By default, the Exchange Manager calls this function if the receiving application doesn't handle the <a href="#">sysAppLaunchCmdExgAskUser</a> launch code or if it returns <code>exgAskDialog</code> from the launch code handler. When the Exchange Manager calls <code>ExgDoDialog</code>, the</p>                                                                                                                                                                                 |

## Exchange Manager

### *ExgDoDialog*

---

dialog displays a message similar to “Do you want to accept ‘John Doe’ into Address Book?” and allows the user to accept or reject the data. If the user clicks OK, the data should be received as an unfiled record.

The Exchange Manager attempts to display a preview of the data in the exchange dialog to provide users with enough information to determine if they want to accept or reject the data. To display the preview data, it calls [ExgNotifyPreview\(\)](#). Applications wishing to support preview mode should respond to the launch code [sysAppLaunchCmdExgPreview](#). See the [ExgNotifyPreview](#) function’s description for more information.

Applications may also want to allow users to select a category in which to accept the incoming data. To do so, handle [sysAppLaunchCmdExgAskUser](#) to call [ExgDoDialog](#) directly and pass it a pointer to an [ExgDialogInfoType](#) structure. The [ExgDialogInfoType](#) structure is defined as follows:

**Prototype**

```
typedef struct {
    UInt16      version;
    DmOpenRef   db;
    UInt16      categoryIndex;
} ExgDialogInfoType;
```

→ *version*

Set this field to 0 to specify version 0 of this structure.

→ *db*

A pointer to an open database that defines the categories the dialog should display.

← *categoryIndex*

The index of the category in which the user wants to file the incoming data.

If *db* is valid, the function extracts the category information from the specified database and displays it in a pop-up list. Upon return, the *categoryIndex* field contains the index of the category the user selected, or [dmUnfiledCategory](#) if the user did not select a category.

If the call to [ExgDoDialog](#) is successful, your application is responsible for retaining the value returned in *categoryIndex* and using it to file the incoming data as a record in that category.

One way to do this is to store the categoryIndex in the socket's appData field (see [ExgSocketType](#)) and then extract it from the socket in your response to the launch code [sysAppLaunchCmdExgReceiveData](#). For example:

---

```
if (cmd == sysAppLaunchCmdExgReceiveData) {
    UInt16 category =
        (ExgSocketPtr)cmdPBP->appData;
    /* other declarations */

    /* Receive the data, and create a new record
    using the received data. indexNew is the
    index of this record. */
    if (category != dmUnfiledCategory) {
        UInt16 attr;
        Err err;
        err = DmRecordInfo(dbP, indexNew, &attr,
            NULL, NULL);

        // Set the category to the one the user
        // specified, and mark the record dirty.
        if ((attr & dmRecAttrCategoryMask) !=
            category) {
            attr &= ~dmRecAttrCategoryMask;
            attr |= category | dmRecAttrDirty;
            err = DmSetRecordInfo(dbP, indexNew,
                &attr, NULL);
        }
    }
}
```

---

Some of the Palm OS built-in applications (Address Book, Memo, and ToDo) use this method of setting the category on data received through beaming. Refer to the example code for these applications provided in the SDK for a more complete example of how to use ExgDoDialog.

When you explicitly call ExgDoDialog, you must set the result field of the sysAppLaunchCmdExgAskUser launch code's parameter block to either exgAskOk (upon success) or exgAskCancel (upon failure) to prevent the system from displaying the dialog a second time.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

Preview mode display in the exchange dialog is implemented only if [4.0 New Feature Set](#) is present.

## ExgGet Function

| <b>Comments</b>               | <p>Applications use this function to request data (initiate a send) from a remote device. Not all exchange libraries support this operation; for example, neither the IR Library nor Bluetooth support it.</p> <p>Before calling this function, the application must initialize the <code>socketP</code> parameter. The socket should identify the exchange library to connect with by providing either a library reference number in the <code>libraryRef</code> field or a URL in the <code>name</code> field. The default exchange library registered for the URL's scheme handles the connection. The socket should also specify what data it is requesting by providing values for at least one of the <code>target</code>, <code>name</code>, and <code>type</code> fields. Specifying the data in the <code>name</code> field is the most common method.</p> |                      |         |                               |                                        |                               |                                  |                          |                                                          |

To provide users with a choice of transport mechanisms, the application can provide a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

If the library is not specified by either URL or library reference number, the Exchange Manager by default uses the IR Library; however, if the `localMode` flag is set, the Local Exchange Library is used instead.

Applications can use `ExgGet` to initiate a send from the Local Exchange Library. For more information, see “[Sending and Receiving Locally](#)” on page 32 of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

If no error is returned, applications should follow this call with one or more calls to [ExgReceive\(\)](#), to receive the data, or [ExgDisconnect\(\)](#), to disconnect.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [ExgPut\(\)](#), [ExgConnect\(\)](#)

## ExgGetDefaultApplication Function

**Purpose**         Retrieves the default application for the specified type of data or the default exchange library for URLs with the specified scheme.

**Declared In**    `ExgMgr.h`

**Prototype**     `Err ExgGetDefaultApplication (UInt32 *creatorIDP,  
                                  UInt16 id, const Char *dataTypeP)`

**Parameters**     $\leftarrow$  *creatorIDP*

A pointer to the creator ID of the default application or default exchange library.

$\rightarrow$  *id*

The registry ID constant identifying the type of data in `dataTypeP`. See [Registry ID Constants](#).

$\rightarrow$  *dataTypeP*

A pointer to a string that contains the type of data for which to retrieve the default application or library. If `dataTypeP` is

a file extension, do not include the period (.). If it is a URL, do not include the colon (:).

**Returns** Returns `errNone` if a match was found or `exgErrNoKnownTarget` if there is no default application or library for this type of data.

**Comments** You might use this function to see which application on this device will receive a particular type of data or to see which library on this device handles URLs of a particular scheme.

For example, to find out which application receives TXT files on this device, do the following:

---

```
UInt32 creatorID;
Err error;
error = ExgGetDefaultApplication(&creatorID,
    exgRegExtensionID, "TXT");
if (!error) {
    //creatorID contains default application.
```

---

To find out which exchange library handles URLs that use the beam prefix, do the following:

---

```
UInt32 creatorID;
Err error;
error = ExgGetDefaultApplication(&creatorID,
    exgRegSchemeID, exgBeamScheme);
if (!error) {
    //creatorID contains default library.
```

---

It's possible to have several applications registered to receive the same type of data, but none of them is the default. When the Exchange Manager receives an object of that type, it selects an application to receive the data, and it selects that same application every time. The selected application effectively becomes the default for the data type even though it is not explicitly set as the default. If this is the case, the `ExgGetDefaultApplication` function returns the creator ID of this de-facto default application.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgGetRegisteredApplications\(\)](#),  
[ExgGetRegisteredTypes\(\)](#), [ExgRegisterDatatype\(\)](#),  
[ExgSetDefaultApplication\(\)](#)

## ExgGetRegisteredApplications Function

| <b>Purpose</b>     | Retrieves a list of all applications registered to receive data of a specified type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | ExgMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <pre>Err ExgGetRegisteredApplications     (UInt32 **creatorIDsP, UInt32 *numAppsP,      Char **namesP, Char **descriptionsP,      UInt16 id, const Char *dataTypeP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p>← <i>creatorIDsP</i><br/>An array of the creator IDs of the applications registered to receive objects of this type. Pass NULL for this parameter if you only want to know how many applications are registered for this type.</p> <p>← <i>numAppsP</i><br/>The number of applications registered to receive objects of this type. This is the number of elements in the <i>creatorIDsP</i> array, the <i>namesP</i> array, and the <i>descriptionsP</i> array.</p> <p>← <i>namesP</i><br/>A packed list of strings, suitable for passing to <a href="#">SysFormPointerArrayToStrings()</a>, containing the names of the applications or libraries. Each string is no more than <code>exgMaxTitleLen</code> characters. Pass NULL for this parameter if you don't want to retrieve it.</p> <p>← <i>descriptionsP</i><br/>A packed list of strings, suitable for passing to <a href="#">SysFormPointerArrayToStrings</a>, containing the descriptions of the applications or libraries. Descriptions are specified when the applications or libraries register for data. Each string is no more than <code>exgMaxDescriptionLength</code> characters. Pass NULL for this parameter if you don't want to retrieve it.</p> <p>→ <i>id</i><br/>The registry ID constant identifying the type of data in <i>dataTypeP</i>. See <a href="#">Registry ID Constants</a>.</p> <p>→ <i>dataTypesP</i><br/>A pointer to a tab-delimited, null-terminated string listing the items to register. (Use <code>\t</code> for the tab character.) Each</p> |

item in the string must be no more than `exgMaxTypeLength` characters. There can be no more than 16 types total.

**Returns** Returns `errNone` upon success or `exgMemError` if the function cannot allocate space for the creator IDs, names, or descriptions.

---

**IMPORTANT:** This function allocates enough space for the `creatorIDsP`, `namesP`, and `descriptionsP` arrays as long as you do not pass `NULL` for the parameters. You are still responsible for freeing these arrays.

---

**Comments** You might use this function to see which applications on this device can receive a particular type of data or to see which libraries on this device handle URLs of a particular scheme. You can also use it to build a list of choices from which the user can select a default application or default exchange library for a particular data type or URL scheme. For example, iMessenger uses this function to build a list of mailto handlers so that the user can choose one of them to be the default.

The Exchange Manager itself uses `ExgGetRegisteredApplications` to find exchange libraries when it is given a URL that begins with a question mark (?). It displays the returned list to the user in the Send With dialog.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

| <b>Comments</b>                  | The Exchange Manager uses this function to determine which application should be launched to receive incoming data. Applications and libraries may call this function as well.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                      |         |                                  |                                                                                                 |                                  |                                                       |

`ExgGetTargetApplication` determines the target application by doing the following:

- If the `socketP->target` field contains a creator ID, the Exchange Manager searches the registry to see if an application is registered for that creator ID as the default application. If the registry does not contain an entry for the creator ID, it checks to see if the application identified by the creator ID is installed on this device. If an application is found for the target, that is the application returned.
- If the `socketP->type` field contains a MIME type, the Exchange Manager searches the registry for an application registered to receive objects of that type. If one is found, that is the application returned.
- If the `socketP->name` field contains a period (`.`), the portion after the last period is taken to be the file extension. The Exchange Manager searches the registry for an application registered to receive a file with the specified extension. If one is found, that is the application returned. If not, `exgErrNoKnownTarget` is returned.

If more than one application is registered for the target, type, or file extension, this function returns the one that is registered as the default. If no application is registered as the default, then a specific application is chosen. The Exchange Manager chooses this same application each time. That is, each time a file with a TXT extension is sent with no target or MIME type specified, the `ExgGetTargetApplication` returns the same application to handle the receipt.

Set the `unwrap` parameter to `true` if the object was sent as part of another object, such as a `vStock` object that was sent as an attachment to an e-mail message. In this case, the Exchange Manager searches for an application that registered to receive the target, the type, or the file extension of the `vStock` object with the `exgUnwrap` flag set. If an application is found, the `vStock` object is delivered, and the exchange library should discard the object that contained it (the e-mail message). If there is no application registered to receive the data with the `exgUnwrap` flag set, this function returns `exgErrNoKnownTarget`. In this case, the exchange library should call [`ExgNotifyReceive\(\)`](#) again passing the entire e-mail message instead of just the `vStock` attachment.

## Exchange Manager

### *ExgNotifyGoto*

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgSetDefaultApplication\(\)](#), [ExgNotifyPreview\(\)](#),  
[ExgNotifyReceive\(\)](#), [ExgRegisterDatatype\(\)](#)

## ExgNotifyGoto Function

**Purpose** Launches the target application using [sysAppLaunchCmdGoto](#).

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgNotifyGoto (ExgSocketType *socketP,  
                          UInt16 flags)`

**Parameters**  $\rightarrow$  *socketP*  
A socket identifying the object to deliver (see [ExgSocketType](#)). The `goToCreator` field contains the application to be launched, and the `goToParams` field contains data for the launch code's parameter block.

$\rightarrow$  *flags*  
Not currently used. Pass 0 for this parameter.

**Returns** Returns one of the following error codes:

|                                                             |                                                                         |
|-------------------------------------------------------------|-------------------------------------------------------------------------|
| <code>errNone</code>                                        | Success or the <code>goToCreator</code> field is empty                  |
| <code>dmErr...</code> (one of the data manager error codes) | The specified application could not be found                            |
| <code>memErrNotEnoughSpace</code>                           | Not enough memory available to create the launch code's parameter block |

**Comments** Exchange libraries call this function if they want to support immediate display of the received object. Applications do not call this function.

Most exchange libraries should call `ExgNotifyGoto` after the return from [ExgNotifyReceive\(\)](#) so that the user can inspect the newly received data. If the exchange library is most often used by a single application that does not require the launch code, this call to `ExgNotifyGoto` can be skipped. For example, the SMS Library does not call `ExgNotifyGoto`. SMS messages are received by the

SMS Messenger application, which does not launch upon receiving data.

ExgNotifyGoto only launches an application if one is specified in the goToCreator field and the noGoTo parameter is false. If a goToCreator is not specified, it is not considered an error. This gives the application a way to override the default behavior.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive\(\)](#), [ExgDisconnect\(\)](#)

## ExgNotifyPreview Function

**Purpose** Displays a preview in the exchange dialog of the data to be received.

**Declared In** ExgMgr.h

**Prototype** Err ExgNotifyPreview (ExgPreviewInfoType \*infoP)

**Parameters**  $\leftrightarrow$  infoP

An [ExgPreviewInfoType](#) structure containing information about the preview operation.

**Returns** Returns one of the following error codes:

|                     |                                                                  |
|---------------------|------------------------------------------------------------------|
| errNone             | Success                                                          |
| exgErrNotSupported  | The exchange library doesn't support preview mode                |
| exgErrNoKnownTarget | There is no application registered to receive the type of object |

Other error codes depend on the application.

**Comments** This function performs the preview operation specified in the op field of the infoP parameter. The [ExgDoDialog\(\)](#) function calls this function to show a data preview in the exchange dialog. Exchange libraries might want to call this function in certain circumstances. An application rarely calls this function, but it may do so if it displays its own dialog in response to the launch code [sysAppLaunchCmdExgAskUser](#).

ExgNotifyPreview uses [ExgGetTargetApplication\(\)](#) to determine the appropriate target application for this data and then

## Exchange Manager

### *ExgNotifyReceive*

---

launches that application with the launch code [sysAppLaunchCmdExgPreview](#), passing `infoP` as the parameter block. The application responds to this launch code by accepting the connection, receiving the data from the exchange library, and depending on the operation requested, drawing the data into the `infoP->bounds` rectangle or returning it in the `infoP->string` field, and then disconnecting. The `ExgDoDialog` function uses the returned information to draw the preview portion of the dialog.

If the preview data is a string, the `ExgNotifyPreview` provides a series of fallback strings that are used if the exchange library doesn't support preview or the application doesn't respond to the launch code. If the application fails to return a string, this function provides one of the following:

- the data's description from `socketP->description`
- the filename in `socketP->name`
- the target application's description as stored in the exchange registry
- the MIME type in `socketP->type`
- the file extension in `socketP->name`

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive\(\)](#), [ExgDisconnect\(\)](#)

## ExgNotifyReceive Function

**Purpose** Delivers an object to the appropriate application using the registry.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgNotifyReceive (ExgSocketType *socketP,  
                          UInt16 flags)`

**Parameters**  $\leftrightarrow$  *socketP*

A pointer to the socket structure (see [ExgSocketType](#)).

$\rightarrow$  *flags*

A bit field. Pass 0 or a combination of the following constants (OR the constants together to specify more than one):

`exgUnwrap`

The object being delivered should only be handled by an application that registered to receive it with the `exgUnwrap` flag set.

`exgNoAsk`

Do not ask the user to confirm receipt of data. If this constant is passed, the target application does not receive the [sysAppLaunchCmdExgAskUser](#) launch code, and the Exchange Manager does not call [ExgDoDialog\(\)](#) to display the user confirmation dialog.

`exgGet`

Specifies that this is a request for the application to send data rather than to receive data.

**Returns** Returns one of the following error codes:

`errNone` Success

`exgErrTargetMissing` The target field contains a creator ID, but the application with that creator ID does not exist

`exgErrNoKnownTarget` No application is registered to receive the data type

`exgErrUserCancel` The user cancelled the operation

Other error codes depend on the application that is launched.

**Comments** Exchange libraries call this function to initiate a receive operation on the receiving device. Applications do not call this function.

The `ExgNotifyReceive` function uses [ExgGetTargetApplication\(\)](#) to determine which application should receive the data, then sends that application the appropriate launch codes.

If the `flags` parameter is 0, a receive operation is assumed. The `ExgNotifyReceive` function does the following:

1. It sends the application the [sysAppLaunchCmdExgAskUser](#) launch code.

## Exchange Manager

### *ExgNotifyReceive*

---

2. If the application returns `exgAskDialog` or does not respond to the launch code, it calls `ExgDoDialog()`, which sends the application the `sysAppLaunchCmdExgPreview` launch code to have the application receive preview data for the dialog.
3. It sends the application the `sysAppLaunchCmdExgReceiveData` launch code to tell the application to receive the data.

If the `flags` field contains the `exgNoAsk` flag, the first and second steps are skipped.

If the `flags` field contains `exgGet`, this function is a request for data to send to the remote device, not a request to receive data from the remote device. In this case, `ExgNotifyReceive` launches the target application with the `sysAppLaunchCmdExgGetData` launch code.

If the `flags` field has the `exgUnwrap` bit set, it means that the object to be received was sent as part of another object, and it should only be sent to an application that registered to receive it with the `exgUnwrap` flag set. For example, if the exchange library receives an e-mail message with an attached vStock object, the exchange library may call `ExgNotifyReceive` with the `exgUnwrap` flag set and a socket that describes the vStock data type to see if there is an application that registered to receive it directly. If no application is registered to receive vStock objects with the `exgUnwrap` flag set, `ExgNotifyReceive` returns `exgErrNoKnownTarget`. The exchange library should then call `ExgNotifyReceive` again, but this time without the `exgUnwrap` flag and with a socket that describes the e-mail message data type. This second call sends the object to the application registered to receive the e-mail message rather than its vStock attachment. That application may extract the vStock attachment from the message and use the Local Exchange Library to send it to an application registered to receive vStock objects normally (without the `exgUnwrap` flag).

#### **Compatibility**

Implemented only if [3.0 New Feature Set](#) is present.

`ExgNotifyReceive` was a system use only function until the release of Palm OS 4.0.

If the [4.0 New Feature Set](#) is **not** present, the `flags` parameter is not supported, so libraries cannot suppress the exchange dialog, send

objects with attachments, or perform a get operation. These features are all added in the [4.0 New Feature Set](#). Also, if the 4.0 new feature set is not present, this function performs the equivalent of [ExgNotifyGoto\(\)](#) after the application has returned from receiving data. Exchange libraries wishing to support this functionality should call `ExgNotifyGoto` immediately after calling `ExgNotifyReceive`.

| <b>Comments</b>                   | <p>Applications call this function to start a send operation.</p> <p>If the connection does not already exist, this function establishes one. You must create and initialize an <code>ExgSocketType</code> structure containing information about the data to send and the destination application. All unused fields in the structure <b>must</b> be set to 0.</p>                                                                                                                                          |                      |         |                               |                                        |                          |                                          |                                   |                                                                 |

## Exchange Manager

### *ExgPut*

---

If no error is returned, this call **must** be followed by [ExgSend\(\)](#), to begin sending data, or [ExgDisconnect\(\)](#), to disconnect. You may need to call [ExgSend](#) multiple times to send all the data.

The socket's `libraryRef` field or the `name` field must identify the library that performs the transfer. The `libraryRef` field identifies the exchange library by its library reference number. The `name` field identifies the library by URL. The socket should also specify what data is being sent by providing values for at least one of the `target`, `name`, and `type` fields. Use of the `name` field is the most common method.

To provide users with a choice of transport mechanisms, the application can provide a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

For example, many applications on Palm OS 4.0 or higher support a `Send` command. This command generates a URL with the prefix `exgSendPrefix` (see [Predefined URL Prefixes](#)). The Exchange Manager displays a dialog containing a list of libraries registered for that URL scheme. The user selects an exchange library, and that library's `ExgLibSend` function is called.

If the library is not specified by either URL or library reference number, the Exchange Manager by default uses the IR Library; however, if the `localMode` flag is set, the Local Exchange Library is used instead.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

Support for identifying exchange libraries by URL is implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [ExgDisconnect\(\)](#), [ExgSend\(\)](#), [ExgConnect\(\)](#)

## ExgReceive Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Exchange Manager

### *ExgRegisterDatatype*

---

received. However, exchange libraries can provide their own user interface that is shown during this call, is updated as necessary, and allows the user to cancel the operation in progress.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present. Preview mode and [ExgGet\(\)](#) are only supported if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive\(\)](#)

## ExgRegisterDatatype Function

**Purpose** Registers an application to receive a specific type of data, or registers an exchange library to handle specific URL schemes.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgRegisterDatatype (UInt32 creatorID,  
                                UInt16 id, const Char *dataTypesP,  
                                const Char *descriptionsP, UInt16 flags)`

**Parameters**

- *creatorID*  
The creator ID of the registering application or exchange library.
- *id*  
A registry ID constant identifying the type of the items being registered. See [Registry ID Constants](#).
- *dataTypesP*  
Pointer to a tab-delimited, null-terminated string listing the items to register. (Use "\t" for the tab character.) To unregister, pass a NULL value. Each item in the string must be no more than `exgMaxTypeLength` characters. There can be no more than 16 types total.

---

**NOTE:** If specifying file extensions, do not include the period (.) that precedes the extension. If specifying URL prefixes, do not include the colon (:) at the end of the prefix.

---

→ *descriptionsP*  
Pointer to a tab-delimited, null-terminated string that lists descriptions for the items in the *dataTypesP* parameter. (Use "\t" for the tab character.) Each description must be no

longer than `exgMaxDescriptionLength`. Pass `NULL` to leave out the descriptions.

There must either be one description for all types or the number of descriptions must match the number of types.

The descriptions are used in dialogs displayed by Exchange Manager to identify applications or libraries.

→ *flags*

A bit field specifying registration options. Currently, only one bit is used: the `unwrap` bit. Pass the `exgUnwrap` constant to specify that the application is registering to receive objects of this type directly if the object is sent as part of another object. For example, if a `vStock` object is sent as an attachment to an email message, the Exchange Manager should send the `vStock` object to this application directly rather than sending the message to the email application.

**Returns** Returns `errNone` if successful, `exgMemError` if there is not enough memory to save the registration info, or one of the data manager error codes (`dmErr...`).

**Comments** Both applications and exchange libraries use this function to register with the Exchange Manager to receive certain types of data.

Applications must register with the Exchange Manager to receive data objects that do not specifically target that application using the creator ID in the `target` field.

Exchange libraries register to receive data with certain URL schemes. If an exchange library is not registered to receive URLs, it only handles the receipt and sending of data if its library reference number is explicitly specified in the [ExgSocketType](#) structure. Otherwise, the IR Library handles all incoming data for which a library could not be found.

Both applications and libraries should register to receive data as soon as possible after they are installed and as soon as possible after a hard reset. For example, applications can call `ExgRegisterDatatype` in response to the [sysAppLaunchCmdSyncNotify](#) launch code, which they receive immediately after install. Exchange libraries implemented as applications can also use this strategy. Exchange libraries implemented as shared libraries should call `ExgRegisterDatatype` in their startup functions.

## Exchange Manager

### *ExgRegisterDatatype*

---

Make only one call to `ExgRegisterDatatype` per registry type. If you want to register to receive multiple items, use a tab character (`\t`) to separate the items. If you were to, for example, make one call to register for the DOC file extension and one call to register for the TXT extension, the second call overwrites the first. However, if you want to register with the `exgUnwrap` flag set, make one call without the `exgUnwrap` flag and one call with the `exgUnwrap` flag set. The application registered with the `exgUnwrap` flag set is stored in a different part of the registry.

Specify `exgRegExtensionID` to register to receive data that has a filename with a particular extension. For example, if your application wants to receive files with a TXT extension, it could register like this:

---

```
ExgRegisterDatatype(myCreator,  
    exgRegExtensionID, "TXT", NULL, 0);
```

---

If the application wants to receive files with a TXT extension or with a DOC extension, it could register like this:

---

```
ExgRegisterDatatype(myCreator,  
    exgRegExtensionID, "TXT\tDOC", NULL, 0);
```

---

Specify `exgRegTypeID` to register to receive data with a specific MIME type. For example, if your application wants to receive “setext” text files, it could register like this:

---

```
ExgRegisterDatatype(myCreator, exgRegTypeID,  
    "text/x-setext", NULL, 0);
```

---

Specify `exgRegCreatorID` to register to receive data targeted for a particular creator ID. For example, if your application wants to handle all data intended for the `ToDo` application, it could register like this:

---

```
Char toDoCreatorStr[5];  
MemMove(toDoCreatorStr, sysFileCToDo, 4);  
toDoCreatorStr[4] = chrNull;  
ExgRegisterDatatype(myCreator, exgRegCreatorID,  
    toDoCreatorStr, NULL, 0);
```

---

---

**NOTE:** To override one application's receipt of data, you need to also set your application as the default for this creator ID. See [ExgSetDefaultApplication\(\)](#).

---

Most exchange libraries will want to register for a unique URL scheme that identifies only that library, plus they should register for a more general scheme, such as the send scheme (`exgSendScheme`), which causes the library to be listed in the Send With dialog when the user performs the Send command. The registry ID constant for URL prefixes is `exgRegSchemeID`.

---

```
ExgRegisterDatatype(myLibCreator,  
    exgRegSchemeID, myScheme "\t" exgSendScheme,  
    NULL, 0);
```

---

Registrations are active until a hard reset or until the application or library is removed. The registration information is preserved across a soft reset. When an application is removed, its registry information is also automatically removed from the registry, so there is not normally a need to unregister. If you want to unregister, you can call `ExgRegisterDatatype` with a `NULL` value for the `dataTypesP` parameter.

Multiple applications can be registered to receive the same type of data. If this is the case, the application that is registered as the default (using [ExgSetDefaultApplication\(\)](#)) is the one that receives the data unless the exchange socket explicitly specifies another application should receive it. If there is no default specified, the Exchange Manager determines a default.

Multiple libraries may also be registered to receive the same type of URL. In this case, if the URL begins with a question mark (?), the Exchange Manager displays a dialog so that the user can select which exchange library to use. If the URL does not begin with a question mark, the exchange library registered as the default is used. If there is no default specified, the Exchange Manager determines a default.

## Exchange Manager

### *ExgRegisterData*

---

- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.  
ExgRegisterDatatype replaces the [ExgRegisterData\(\)](#) function.
- See Also** [ExgRegisterData\(\)](#), [ExgGetTargetApplication\(\)](#),  
[ExgPut\(\)](#), [ExgGetDefaultApplication\(\)](#),  
[ExgGetRegisteredApplications\(\)](#),  
[ExgGetRegisteredTypes\(\)](#)

## ExgRegisterData Function

- Purpose** Registers an application to receive a specific type of data. This function is deprecated and replaced with [ExgRegisterDatatype\(\)](#).
- Declared In** ExgMgr.h
- Prototype** Err ExgRegisterData (UInt32 creatorID, UInt16 id,  
const Char \*dataTypesP)
- Parameters**
- *creatorID*  
Creator ID of the registering application.
  - *id*  
Registry ID identifying the type of the items being registered. Specify exgRegExtensionID or exgRegTypeID.
  - *dataTypesP*  
Pointer to a tab-delimited, null-terminated string listing the items to register. (Use \t for the tab character.) These include file extensions or MIME types. To unregister, pass a NULL value.
- Returns** Returns errNone if successful, otherwise, one of the data manager error codes (dmErr...).
- Comments** Applications that wish to receive data from anything other than another Palm Powered™ handheld running the same application must use this function to register for the kinds of data they can receive. Call this function when your application is loaded on the device.
- Compatibility** This function corresponds to the Palm OS 3.5 version of [ExgRegisterDatatype\(\)](#). It is implemented only if [3.0 New Feature Set](#) is present.

| <b>Comments</b>                   | <p>The <code>ExgRequest</code> function is similar to <a href="#">ExgGet ()</a> in that both are used to request data. The difference is that the application that calls <code>ExgGet</code> is always the application that receives the data. When you call <code>ExgRequest</code>, the application that receives the data is the application that is registered to receive it. For example, using <code>ExgRequest</code>, it is possible for one application to use the Exchange Manager to retrieve a vCard using any supported transport mechanism and have that data sent directly to the Address Book application instead of to the calling application.</p> <p>The <code>socketP</code> passed to this function identifies the exchange library using a URL in the name field. The application must know beforehand the proper URL prefix for the exchange library with which it wants to connect. See <a href="#">Predefined URL Prefixes</a> for a list of URL prefixes that the Exchange Manager provides.</p> <p>If the provided URL begins with a question mark (?) and there are several exchange libraries registered for the specified URL scheme,</p> |                      |         |                               |                                        |                                   |                                                                |                                |                                                        |

## Exchange Manager

### *ExgSend*

---

the Exchange Manager displays a dialog from which the user selects the appropriate transport mechanism.

If the Exchange Manager cannot find a library that is registered for the specified URL, it assumes that an application is registered to receive the URL, and it launches that application with the [sysAppLaunchCmdGoToURL](#) launch code.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgGet\(\)](#), [ExgNotifyReceive\(\)](#)

## ExgSend Function

**Purpose** Sends data to the destination device.

**Declared In** `ExgMgr.h`

**Prototype**

```
UInt32 ExgSend (ExgSocketType *socketP,  
                const void *bufP, UInt32 bufLen, Err * err)
```

**Parameters**  $\rightarrow$  *socketP*  
A pointer to the socket structure (see [ExgSocketType](#)). A value must be provided for the `libraryRef` field. The structure should also contain values for the `target`, `type`, or `name` fields.

$\rightarrow$  *bufP*  
A pointer to the data to send.

$\rightarrow$  *bufLen*  
The number of bytes to send.

$\leftarrow$  *err*  
A pointer to an error code result.

**Returns** Returns the number of bytes actually sent, normally the same number as specified in `bufLen`. An error code is returned in the address indicated by `err`. The error code `exgErrUserCancel` is returned if the user cancels the operation.

May display a fatal error message if the `socketP` parameter does not contain a value for the `libraryRef` field.

**Comments** Call this function one or more times to send all the data, following a successful call to [ExgPut\(\)](#). After sending the data, call [ExgDisconnect\(\)](#) to terminate the connection.

The exchange library may break large amounts of data into multiple packets or assemble small send commands together into larger packets, but the application will not be aware of these transport level details.

This function blocks the application until all the data is sent. However, the exchange library may provide its own user interface that is updated as necessary and allows the user to cancel the operation in progress.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.  
**See Also**        [ExgReceive\(\)](#), [ExgGet\(\)](#)

## ExgSetDefaultApplication Function

**Purpose**            Sets the application that receives a specified type of data by default. This function also sets the default exchange library that handles particular URL schemes.

**Declared In**      ExgMgr.h

**Prototype**        Err ExgSetDefaultApplication (UInt32 creatorID,  
                                 UInt16 id, const Char \*dataTypeP)

**Parameters**      → *creatorID*  
                      The creator ID of the application or library that should become the default for this type of data.  
                      → *id*  
                      A registry ID constant identifying the type of data in *dataTypeP*. See [Registry ID Constants](#).  
                      → *dataTypeP*  
                      A pointer to a null-terminated string containing the desired type of data.

---

**NOTE:** If specifying a file extension, do not include the period (.) that precedes the extension. If specifying a URL prefix, do not include the colon (:) at the end of the prefix.

---

**Returns**           Returns `errNone` upon success or `exgErrNoKnownTarget` if the specified application is not registered to receive the specified data type.

## Exchange Manager

### *ExgSetDefaultApplication*

---

**Comments** This function sets the default application that receives data of a certain type when no target is specified and the default exchange library that handles URLs with a certain prefix if no library reference number is specified.

Palm™ strongly recommends that applications allow the user to determine which application should become the default recipient for a data type. To do so, an application can use [ExgGetRegisteredApplications\(\)](#) to get the list of applications registered for the same type of data as it is, and then display a dialog listing those applications and allow the user to select it. Then it should call `ExgSetDefaultApplication` with the user-specified default.

If you call `ExgSetDefaultApplication` with an application or library that is already the default, this function has no effect.

An application can become the default for its own creator ID even if it has not specifically registered to receive its own creator ID. That is, suppose several applications are registered to receive objects targeted for the `ToDo` application's creator ID. The `ToDo` application itself is not registered for its own creator ID, as it is not necessary to do so. However, an application can use code like the following to set the `ToDo` application as the default for its own creator ID.

---

```
Char toDoCreatorStr[5];
MemMove(toDoCreatorStr, sysFileCToDo, 4);
toDoCreatorStr[4] = chrNull;
ExgSetDefaultApplication(sysFileCToDo,
    exgRegCreatorID, toDoCreatorStr);
```

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## Application-Defined Functions

### ExgDBDeleteProcPtr Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Handles the case where a database with an identical name already exists on the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <pre>Boolean (*ExgDBDeleteProcPtr) (const char* nameP,<br/>                                UInt16 version, UInt16 cardNo, LocalID dbID,<br/>                                void* userDataP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p>→ <i>nameP</i><br/>A pointer to the name of the identical database.</p> <p>→ <i>version</i><br/>The version of the identical database.</p> <p>→ <i>cardNo</i><br/>The card number of the identical database.</p> <p>→ <i>dbID</i><br/>The database ID of the identical database.</p> <p>→ <i>userDataP</i><br/>The <i>userDataP</i> parameter you passed to <a href="#">ExgDBRead()</a>. If used, this parameter contains any application-specific data you find necessary. If the <a href="#">ExgDBReadProcPtr()</a> function is implemented using Exchange Manager calls, this often contains the <a href="#">ExgSocketType</a> structure.</p> |
| <b>Returns</b>     | Return <code>true</code> to have the <code>ExgDBRead</code> function continue to read the database. Use this return value if you have deleted or moved the existing database or if you want the database to be overwritten. Return <code>false</code> to have <code>ExgDBRead</code> exit without reading the database.                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | This function is called if the Data Manager can't create the incoming database because a database with the same name already exists. You should delete the existing database or take some other action, such as changing the database name. It is appropriate to prompt the user before choosing to delete or move the database.                                                                                                                                                                                                                                                                                                                    |

## ExgDBReadProcPtr Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Reads in the database and pass it to <a href="#">ExgDBRead()</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Err (*ExgDBReadProcPtr) (void* dataP,<br/>                          UInt32* sizeP, void* userDataP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><math>\leftarrow</math> <i>dataP</i><br/>A pointer to a buffer where this function should place the database data. This buffer is allocated in the dynamic heap by <code>ExgDBRead</code>; you don't need to use <a href="#">DmWrite()</a> when filling it.</p> <p><math>\leftrightarrow</math> <i>sizeP</i><br/>The size of <i>dataP</i>. This value is set by <code>ExgDBRead</code> to the number of bytes it expects to receive in <i>dataP</i>. You must set this value to the number of bytes you return in <i>dataP</i> (if it's not the same).</p> <p><math>\rightarrow</math> <i>userDataP</i><br/>The <i>userDataP</i> parameter you passed to <code>ExgDBRead</code>. Pass the <a href="#">ExgSocketType</a> structure if you implement this function using Exchange Manager calls.</p> |
| <b>Returns</b>     | Return an error number, or <code>errNone</code> if there is no error. If this function returns an error, <code>ExgDBRead</code> deletes the database it was creating, cleans up any memory it allocated, then exits, returning the error passed back from this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>    | <code>ExgDBRead</code> is commonly used to receive a database from a beam or from some other transport mechanism. In this case, an appropriate implementation of this callback function is to call <a href="#">ExgReceive()</a> as shown here:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

---

```
Err MyReadDBProc (void *dataP, UInt32 *sizeP,  
                  void *userDataP)  
{  
    Err err = errNone;  
    //userDataP contains ExgSocketType pointer.  
    *sizeP =  
        ExgReceive((ExgSocketType *)userDataP,  
                  dataP, *sizeP, &err);  
    return err;  
}
```

## ExgDBWriteProcPtr Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Writes out the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>ExgMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <code>Err (*ExgDBWriteProcPtr) (const void* dataP,<br/>                              UInt32* sizeP, void* userDataP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p>→ <i>dataP</i><br/>A pointer to a buffer containing the database data, placed there by <a href="#">ExgDBWrite()</a>.</p> <p>↔ <i>sizeP</i><br/>The number of bytes placed in <i>dataP</i> by <code>ExgDBWrite</code>. If you were unable to write out or send all of the data in this chunk, on exit, set <i>sizeP</i> to the number of bytes you did write.</p> <p>→ <i>userDataP</i><br/>The <i>userDataP</i> parameter you passed to <code>ExgDBWrite</code>. You can use it for application-specific data. Pass the <a href="#">ExgSocketType</a> structure if you implement this function using Exchange Manager calls.</p> |
| <b>Returns</b>     | Return an error number, or <code>errNone</code> if there is no error. If this function returns an error, <code>ExgDBWrite</code> closes the database it was reading, cleans up any memory it allocated, then exits, returning the error passed back from this function.                                                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | <code>ExgDBWrite</code> is commonly used to write a database that is going to be beamed to another device (or sent through some other transport mechanism). In this case, an appropriate implementation of this callback function is to call <a href="#">ExgSend()</a> as shown here:                                                                                                                                                                                                                                                                                                                                               |

---

```
Err MyWriteDBProc (void *dataP, UInt32 *sizeP,  
                  void *userDataP)  
{  
    Err err = errNone;  
    //userDataP contains ExgSocketType pointer.  
    *sizeP =  
        ExgSend((ExgSocketType *)userDataP,  
                dataP, *sizeP, &err);  
    return err;  
}
```

---

## **Exchange Manager**

*ExgDBWriteProcPtr*

---

# Exchange Library

---

The Exchange Library API described in this chapter and declared in `ExgLib.h` specifies a minimal set of functions that all exchange libraries must implement. This chapter is directed towards developers who use or create exchange libraries. Developers creating an exchange library should also read the [Exchange Libraries](#) chapter of the *Palm OS Programmer's Companion*, vol. II, *Communications*.

## Exchange Library Functions

### ExgLibAccept Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Accept an incoming connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>Err ExgLibAccept (UInt16 libRefnum,<br/>ExgSocketType *exgSocketP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <code>libRefnum</code><br/>Reference number of this exchange library.</p> <p>→ <code>exgSocketP</code><br/>A pointer to the socket structure (see <a href="#">ExgSocketType</a>).</p>                                                                                                                                                                                                                                                                                                                   |
| <b>Returns</b>     | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if a preview is in progress and the exchange library does not support preview. Other error codes are defined by each exchange library.                                                                                                                                                                                                                                                                                 |
| <b>Comments</b>    | <p>The Exchange Manager's <a href="#">ExgAccept()</a> function simply calls <code>ExgLibAccept</code> in the exchange library identified by the <a href="#">ExgSocketType</a> structure passed to <code>ExgAccept</code>. An application calls the Exchange Manager's <code>ExgAccept</code> function when:</p> <ul style="list-style-type: none"> <li>• The application wants to initiate a connection to receive data, which it does in response to <code>sysAppLaunchCmdExgReceiveData</code>.</li> </ul> |

## Exchange Library

### *ExgLibClose*

---

- The application wants to initiate a connection to receive a preview of the data, which it does in response to `sysAppLaunchCmdExgAskUser`.

Any implementation of `ExgLibAccept` should update any progress dialogs to indicate that data is being accepted (or received) into an application.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgLibPut\(\)](#)

## ExgLibClose Function

**Purpose** Library-specific. Although this function is not called by the Exchange Manager, all shared libraries normally implement it.

**Declared In** `ExgLib.h`

**Prototype** `Err ExgLibClose (UInt16 libRefnum)`

**Parameters** `→ libRefnum`  
Reference number of this exchange library.

**Comments** Exchange libraries are free to implement this function for internal or external use. The Exchange Manager does not call it.

## ExgLibConnect Function

**Purpose** Open a connection in preparation for sending or receiving objects.

**Declared In** `ExgLib.h`

**Prototype** `Err ExgLibConnect (UInt16 libRefNum,  
ExgSocketType *exgSocketP)`

**Parameters** `→ libRefNum`  
Reference number of this exchange library.

`↔ exgSocketP`  
A pointer to an [ExgSocketType](#) structure identifying the socket through which objects will be sent or received.

**Returns** Returns `errNone` if no error. If `ExgLibConnect` is not supported by this library, this function returns `exgErrNotSupported`; if its

use is optional, `errNone` is returned. Other error codes are defined by each exchange library.

**Comments** The Exchange Manager may call this function to initiate a connection for sending multiple objects or for performing two-way communications. Some exchange libraries support sending multiple objects but do not support this call. See “[Sending Multiple Objects](#)” on page 16 of *Palm OS Programmer’s Companion*, vol. II, *Communications* for more information.

Not all exchange libraries support this operation. In this case, the first call to [ExgLibPut\(\)](#) must clean up after itself before returning an error. The exchange library should not expect to get an [ExgLibDisconnect\(\)](#) call.

If `ExgLibConnect` is supported and an application calls [ExgConnect\(\)](#), the exchange library should delay any cleanup until `ExgLibDisconnect`, unless `ExgLibConnect` returns an error, in which case it should clean up after itself. The library can expect to get an `ExgLibDisconnect` call if it returns `errNone` from `ExgLibConnect`. If the application does not call `ExgConnect`, the first call to `ExgLibPut` must clean up after itself before returning an error and the exchange library should not expect to get an `ExgLibDisconnect` call.

The Exchange Manager’s `ExgConnect` function calls `ExgLibConnect` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgConnect`. If `ExgLibConnect` is implemented to return `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; the exchange library must put up its own alerts when appropriate.

The exchange library may prompt the user for addressing information.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibControl Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Supply information about the exchange library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | <pre>Err ExgLibControl(UInt16 libRefNum, UInt16 op,                   void *valueP, UInt16 *valueLenP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Returns</b>     | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if the specified operation is not supported by the exchange library. <code>exgErrBadParam</code> is returned if the parameters ( <i>valueP</i> and <i>valueLenP</i> ) are not appropriate for the operation. Additional error codes are defined by each exchange library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | <p><code>ExgLibControl</code> is a general purpose function that performs various minor operations based upon a selector. <code>ExgMgr.h</code> defines three selectors: <code>exgLibCtlGetTitle</code>, which should be supported by all exchange libraries, <code>exgLibCtlGetVersion</code>, and <code>exgLibCtlGetPreview</code>. Additional library-specific selectors should be numbered starting at <code>exgLibCtlSpecificOp</code> (0x8000).</p> <p>Upon receiving <code>exgLibCtlGetTitle</code>, the exchange library must return a library title suitable for use in Exchange Manager dialogs. Exchange libraries that are built as applications should generally return their 'tAIN' resource as their title. Be sure that the title returned through <i>valueP</i> honors the maximum length specified in <i>valueLenP</i>.</p> <p>An exchange library that implements the Palm OS 4.0 version of the Exchange Library API needn't do anything special upon receiving <code>exgLibCtlGetVersion</code>; it should simply return <code>exgErrNotSupported</code>. Otherwise, set <i>valueP</i> to a two-byte value indicating the API version number and return <code>errNone</code>. Note</p> |

that a version number of zero corresponds to the Palm OS 4.0 version of the Exchange Library API.

The `exgLibCtlGetPreview` operation is used by the Exchange Manager to determine whether a given exchange library supports preview. The Exchange Manager assumes that an exchange library supports preview if the exchange library doesn't implement this operation. To indicate that a library does not support preview, set `valueP` to false and return `errNone`.

The Exchange Manager's `ExgControl()` function simply calls `ExgLibControl` in the exchange library identified by the `ExgSocketType` structure passed to `ExgControl`.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibDisconnect Function

**Purpose**    Disconnect a connection made with [ExgLibConnect\(\)](#), [ExgLibAccept\(\)](#), [ExgLibPut\(\)](#), or [ExgLibGet\(\)](#).

**Declared In**    `ExgLib.h`

**Prototype**    `Err ExgLibDisconnect (UInt16 libRefnum,  
                                 ExgSocketType *exgSocketP, Err error)`

**Parameters**    `→ libRefnum`  
                    Reference number of this exchange library.

`→ exgSocketP`  
                    A pointer to an [ExgSocketType](#) structure identifying the socket connection to be disconnected.

`→ error`  
                    The current error state. Used to indicate why the connection is being broken, for example, user cancel or out of memory.

**Returns**    Typically the same error code passed in. However, this function may return an error even if `errNone` is passed in.

**Comments**    `ExgLibDisconnect` may be used to finish reading the data during a preview; in this case, the connection, if any, is not shut down.

Applications call `ExgLibDisconnect` when all data has been sent or the application wants to stop the send process. If the send data process is not completed, the caller should pass an error parameter

## Exchange Library

### *ExgLibGet*

---

indicating why the operation was stopped. `ExgLibDisconnect` is responsible for completing the operation and closing any communication ports if necessary. If data was buffered for sending in `ExgLibSend`, then the disconnect process may actually perform the entire transmit operation. It is important to note that the `ExgLibDisconnect` function can be called for an `ExgLibPut`, `ExgLibAccept` or `ExgLibGet` function. So it is equally important to keep track of the current operation in the [ExgSocketType](#). If dialogs are displayed, this function must update them as appropriate. If there are errors, `ExgLibDisconnect` should display them (if allowed by the application).

If [ExgLibConnect\(\)](#) is not supported, the first call to [ExgLibPut\(\)](#) must clean up after itself before returning an error and the exchange library should not expect to get an `ExgLibDisconnect` call.

If `ExgLibConnect` is supported and an application calls [ExgConnect\(\)](#), the exchange library should delay any cleanup until `ExgLibDisconnect`, unless `ExgLibConnect` returns an error, in which case it should clean up after itself. The library can expect to get an `ExgLibDisconnect` call if it returns `errNone` from `ExgLibConnect`. If the application does not call `ExgConnect`, the first call to `ExgLibPut` must clean up after itself before returning an error and the exchange library should not expect to get an `ExgLibDisconnect` call.

The Exchange Manager's [ExgDisconnect\(\)](#) function simply calls `ExgLibDisconnect` in the exchange library identified by the `ExgSocketType` structure passed to `ExgDisconnect`.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

| <b>Prototype</b>   | <code>Err ExgLibGet(UInt16 libRefNum,<br/>ExgSocketType *exgSocketP)</code> |
| <b>Parameters</b>  | <code>→ libRefNum</code><br>Reference number of this exchange library.      |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | ↔ <i>exgSocketP</i><br>A pointer to the socket structure (see <a href="#">ExgSocketType</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Returns</b>       | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if this operation is not supported by this library. Other error codes are defined by each exchange library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Comments</b>      | <p><code>ExgLibGet</code> informs the library that it should make a connection to the remote device and request information from it. When an exchange library's <code>ExgLibGet</code> function is called, it should fetch the requested data and prepare to deliver it when the application calls <a href="#">ExgReceive()</a>. After <a href="#">ExgLibReceive()</a> is called, possibly more than once, <a href="#">ExgLibDisconnect()</a> follows.</p> <p>The Exchange Manager's <a href="#">ExgGet()</a> function calls <code>ExgLibGet</code> in the exchange library identified in the <a href="#">ExgSocketType</a> structure passed to <code>ExgGet</code>. If an exchange library's implementation of <code>ExgLibGet</code> returns <code>exgErrNotEnoughPower</code>, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## ExgLibHandleEvent Function

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Handle exchange-library-specific events.                                                                                    |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                       |
| <b>Prototype</b>   | <code>Boolean ExgLibHandleEvent (UInt16 libRefnum,<br/>void *eventP)</code>                                                 |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i><br/> Reference number of this exchange library.</p> <p>→ <i>eventP</i><br/> The event to handle.</p>  |
| <b>Returns</b>     | Returns <code>true</code> if the event was handled.                                                                         |
| <b>Comments</b>    | Exchange libraries are free to implement this function for internal or external use. The Exchange Manager does not call it. |

## ExgLibOpen Function

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Library-specific. Although this function is not called by the Exchange Manager, all shared libraries normally implement it.              |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                    |
| <b>Prototype</b>   | <code>Err ExgLibOpen (UInt16 libRefnum)</code>                                                                                           |
| <b>Parameters</b>  | <code>→ libRefnum</code><br>Reference number of this exchange library.                                                                   |
| <b>Comments</b>    | Exchange libraries are free to implement this function for internal or external use. The <code>ExgLibDisconnect</code> does not call it. |

## ExgLibPut Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Signals the start of an object to be transferred to the destination device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Returns</b>     | Returns <code>errNone</code> if no error. Error codes are defined by each exchange library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>    | <p>Opens a connection if necessary. The actual data should be sent using <a href="#">ExgLibSend()</a> after which the connection should be shut down with <a href="#">ExgLibDisconnect()</a>. The exchange library may prompt the user for addressing information.</p> <p>The first time this library is called, it may be necessary to allocate global variables and perform other initialization steps. It is usually a good idea to keep any state information about the open connection in the <code>socketRef</code> field of the <code>exgSocketP</code> structure. This data can then be passed to subsequent operations on that socket.</p> <p><code>ExgLibPut</code> should then check if the <code>socketRef</code> field of <code>exgSocketP</code> has been initialized. In some cases, an application</p> |

may already have filled `socketRef` with addressing information. The use of `socketRef` is entirely up to the exchange library. If `socketRef` is empty, the exchange library needs to fill in any addressing information. In order to do this, the exchange library needs to open its own dialog asking the user for whatever addressing information would be appropriate.

Exchange libraries are responsible for any validation of data entered in the addressing dialog and may use Address Book lookup or other system features to improve the user experience.

Once the user has completed addressing and confirmed the dialog, the exchange library should, in general, call the [Progress Manager](#) to open a progress dialog that remains open during the entire put operation. The progress dialog should not be opened if the `noStatus` option was passed or if the transaction is in asynchronous mode.

If the exchange library is displaying dialogs, it must also look for events and pass them to the Progress Manager.

Other operations within `ExgLibPut` depend on the exchange library. The exchange library may open communications ports and establish remote links at this time. Or it may just open a stream for buffering data until a later operation. If any errors occur in this process, the exchange library is responsible for removing any progress dialogs and returning an error. If displaying progress, the exchange library may also need to display an error using the Progress Manager before returning.

---

**NOTE:** The progress dialog is converted to an error dialog and waits until the user dismisses it. This may occur in `ExgLibPut` or later in [ExgLibDisconnect\(\)](#). It depends on whether the connection was made in `ExgLibPut` or whether it used an existing connection made by a previous call to `ExgLibConnect` or `ExgLibPut`.

---

The first call to [ExgLibPut\(\)](#) must clean up after itself before returning an error if one of the following conditions exists:

- If [ExgLibConnect\(\)](#) is not supported.

## Exchange Library

### *ExgLibReceive*

---

- If `ExgLibConnect` is supported and an application does not call `ExgLibConnect`.

The Exchange Manager's [ExgPut \(\)](#) function calls `ExgLibPut` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgPut`. If `ExgLibPut` returns `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibReceive Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Returns</b>     | The number of bytes received. Returns 0 if the object is complete. <code>ExgLibReceive</code> blocks until at least one byte is available or the object is complete.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | <p>Use after <a href="#">ExgLibGet()</a> or <a href="#">ExgLibAccept()</a> to receive the contents of the object. May be used after <a href="#">ExgLibAccept</a> to examine the contents during a preview.</p> <p><a href="#">ExgLibReceive</a> must update any progress dialogs to indicate that data is being received. The <a href="#">ExgLibReceive</a> should fill the buffer passed as much as possible and return the actual number of bytes that were stored in the buffer. <a href="#">ExgLibReceive</a> must block for at least one byte if the stream is not complete. Returning zero bytes indicates the end of the data.</p> <p>The Exchange Manager's <a href="#">ExgReceive()</a> function simply calls <a href="#">ExgLibReceive</a> in the exchange library identified by the <a href="#">ExgSocketType</a> structure passed to <a href="#">ExgReceive</a>.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## ExgLibRequest Function

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Requests an object using a URL, then has the Exchange Manager send it to the default application registered for the object's type.                                                                                                       |
| <b>Declared In</b> | <a href="#">ExgLib.h</a>                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <pre>Err ExgLibRequest(UInt16 libRefNum,<br/>                  ExgSocketType *socketP)</pre>                                                                                                                                             |
| <b>Parameters</b>  | <p>→ <i>libRefNum</i><br/>Reference number of this exchange library.</p> <p>↔ <i>socketP</i><br/>Pointer to the socket structure (see <a href="#">ExgSocketType</a>). The name field contains the URL of the object being requested.</p> |
| <b>Returns</b>     | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if the exchange library does not support this operation. Other error codes are defined by each exchange library.                                   |
| <b>Comments</b>    | The exchange library may prompt the user for addressing information. The socket's name field may contain a URL with any of the schemes for which the exchange library registered. Not all exchange libraries support this operation.     |

## Exchange Library

### *ExgLibSend*

---

---

**NOTE:** This function is often used to tickle an exchange library to make it check to see if there are new messages. These messages are then delivered as usual. So there may or may not be a specific object being requested.

---

The Exchange Manager's [ExgRequest\(\)](#) function calls `ExgLibRequest` in the exchange library identified by the `ExgSocketType` structure passed to `ExgRequest`. If `ExgLibRequest` returns `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.

**See Also** [ExgRegisterDatatype\(\)](#)

## ExgLibSend Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Send data for an object to a destination device.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Prototype</b>   | <pre>UInt32 ExgLibSend(UInt16 libRefNum,                   ExgSocketType *exgSocketP, const void *bufP,                   UInt32 bufLen, Err *errP)</pre>                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <div><div>→ <i>libRefNum</i><br/>Reference number of this exchange library.</div><div>← <i>exgSocketP</i><br/>A pointer to the socket structure (see <a href="#">ExgSocketType</a>).</div><div>→ <i>bufP</i><br/>A pointer to a buffer containing the data to send.</div><div>→ <i>bufLen</i><br/>The number of bytes to send.</div><div>← <i>errP</i><br/>The error code result. Error codes are defined by each exchange library</div></div> |
| <b>Returns</b>     | Returns the number of bytes sent.                                                                                                                                                                                                                                                                                                                                                                                                              |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | <p>Applications call <a href="#">ExgSend()</a> after <a href="#">ExgPut()</a> and in response to <code>sysAppLaunchCmdExgGetData</code>.</p> <p>This function blocks until all bytes to be sent are actually sent, or until an error occurs (such as device full).</p> <p><code>ExgLibSend</code> may be called any number of times with varying size buffers to transmit information. If dialogs are being displayed, <code>ExgLibSend</code> must keep them updated (perhaps with animation or progress information). <code>ExgLibSend</code> must also check for events and let the Progress Manager handle them.</p> <p>The Exchange Manager's <code>ExgSend</code> function simply calls <code>ExgLibSend</code> in the exchange library identified by the <a href="#">ExgSocketType</a> structure passed to <code>ExgSend</code>.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## ExgLibSleep Function

|                    |                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The device is going to sleep.                                                                                                                                                                                                                                           |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <code>Err ExgLibSleep(UInt16 libRefnum)</code>                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>→ <i>libRefnum</i></p> <p>Reference number of this exchange library.</p>                                                                                                                                                                                             |
| <b>Returns</b>     | Returns <code>errNone</code> if no error. Error codes are defined by each exchange library.                                                                                                                                                                             |
| <b>Comments</b>    | The device goes into sleep mode when the user turns the device off, the auto-off timer expires, or power is low. All shared libraries must implement <code>ExgLibSleep</code> ; however, no processing is required and simply returning <code>errNone</code> is enough. |

---

**IMPORTANT:** Libraries must return from this function quickly to allow sufficient time for emergency shutdown situations (removal of batteries, for example).

---

## ExgLibWake Function

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The device is waking up.                                                                                                                                                                                      |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                         |
| <b>Prototype</b>   | <code>Err ExgLibWake (UInt16 libRefnum)</code>                                                                                                                                                                |
| <b>Parameters</b>  | <code>→ libRefnum</code><br>Reference number of this exchange library.                                                                                                                                        |
| <b>Returns</b>     | Returns <code>errNone</code> if no error. Error codes are defined by each exchange library.                                                                                                                   |
| <b>Comments</b>    | The device wakes up when the user turns the device on. All shared libraries must implement <code>ExgLibWake</code> , although no processing is required; it is enough to simply return <code>errNone</code> . |

# IR Library

---

The IR (InfraRed) library is a shared library that provides a direct interface to the IR communications capabilities of the Palm OS®. This chapter provides reference material for the IR library API:

- [IR Library Data Structures](#)
- [IR Library Constants](#)
- [IR Stack Callback Events](#)
- [IR Library Functions](#)
- [IAS Functions and Macros](#)
- [Application-Defined Functions](#)

The header file `irlib.h` declares the IR library API. For more information on the IR library, see the chapter “[Beaming \(Infrared Communication\)](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## IR Library Data Structures

This section lists some of the more important data types used by the IR library functions.

### IrConnect Struct

**Purpose** The `IrConnect` structure is used to manage an IrLMP or Tiny TP connection.

**Prototype**

```
typedef struct _hconnect {
    UInt8 lLsap;
    UInt8 rLsap;
    UInt8 flags;
    UInt8 reserved;
    IrCallback callBack;
    IrPacket packet;
```

```
ListEntry packets;  
UInt16 sendCredit;  
UInt8 availCredit;  
UInt8 dataOff;  
} _hconnect;
```

#### Field Descriptions

|             |                                                    |
|-------------|----------------------------------------------------|
| lLsap       | The local LSAP on which this connection listens.   |
| rLsap       | The LSAP assigned to the remote side.              |
| flags       | For system use only.                               |
| reserved    | Reserved for future use.                           |
| callBack    | Pointer to callback function. For system use only. |
| packet      | For system use only.                               |
| packets     | List of packets to send.                           |
| sendCredit  | Amount of credit from peer.                        |
| availCredit | Amount of credit to give to peer.                  |
| dataOff     | Amount of data less than IrLAP size.               |

#### IrPacket Struct

**Purpose** The IrPacket structure is used for sending IrDA packets.

**Prototype**

```
typedef struct _IrPacket {  
    ListEntry node;  
    UInt8 *buff;  
    UInt16 len;  
    IrConnect* origin;  
    UInt8 headerLen;  
    UInt8 header[14];  
    UInt8 reserved;  
} IrPacket;
```

### Field Descriptions

|                        |                                                                  |
|------------------------|------------------------------------------------------------------|
| <code>node</code>      | For system use only.                                             |
| <code>buff</code>      | Pointer to the send data buffer.                                 |
| <code>len</code>       | Number of bytes in data buffer.                                  |
| <code>origin</code>    | Pointer to connection that owns the packet. For system use only. |
| <code>headerLen</code> | Number of bytes contained in the header. For system use only.    |
| <code>header</code>    | Storage for header. For system use only.                         |
| <code>reserved</code>  | Reserved for future use.                                         |

---

**IMPORTANT:** The `node` field must be the first field in the structure. It is used internally by the stack.

---

## IrIASObject Struct

**Purpose** The `IrIASObject` structure is used as storage for an IAS object managed by the local IAS server. An object of this type is passed as the `obj` parameter to the [IrIAS\\_Add\(\)](#) function.

**Prototype**

```
typedef struct _IrIasObject {
    UInt8 *name;
    UInt8 len;
    UInt8 nAttribs;
    IrIasAttribute* attribs;
} IrIasObject;
```

### Field Descriptions

|                       |                                    |
|-----------------------|------------------------------------|
| <code>name</code>     | Pointer to name of object.         |
| <code>len</code>      | Length of object name.             |
| <code>nAttribs</code> | Number of attributes.              |
| <code>attribs</code>  | Pointer to an array of attributes. |

## **IrIasQuery Struct**

**Purpose** The IrIasQuery structure is used to perform IAS queries. The IrIasQuery object is passed as the token parameter to functions such as [IrIAS\\_Query\(\)](#) and [IrIAS\\_Next\(\)](#).

**Prototype**

```
typedef struct _IrIasQuery {
    UInt8 queryLen;
    UInt8 reserved;
    UInt8 *queryBuf;
    UInt16 resultBufSize;
    UInt16 resultLen;
    UInt16 listLen;
    UInt16 offset;
    UInt8 retCode;
    UInt8 overFlow;
    UInt8 *result;
    IrIasQueryCallBack callBack;
} _IrIasQuery;
```

### **Field Descriptions**

|               |                                                    |
|---------------|----------------------------------------------------|
| queryLen      | Total length of the query.                         |
| reserved      | Reserved for future use.                           |
| queryBuf      | Pointer to buffer containing the query.            |
| resultBufSize | Size of the result buffer.                         |
| resultLen     | Actual number of bytes in the result buffer.       |
| listLen       | Number of items in the result list.                |
| offset        | Offset into the results buffer.                    |
| retCode       | Return code of operation.                          |
| overFlow      | Set to true if result exceeded result buffer size. |
| result        | Pointer to buffer containing result.               |
| callBack      | Pointer to query callback function.                |

## IrCallbackParms Struct

**Purpose** The IrCallbackParms structure is used to pass information from the stack to the upper layer of the stack (application). Not all fields are valid at any given time. The type of event determines which fields are valid. The IrCallbackParms object is passed as the second parameter to the IrCallback function.

**Prototype**

```
typedef struct {
    IrEvent event;
    UInt8 reserved1;
    UInt8 *rxBuff;
    UInt16 rxLen;
    IrPacket* packet;
    IrDeviceList* deviceList;
    IrStatus status;
    UInt8 reserved2;
} IrCallBackParms;
```

### Field Descriptions

|            |                                    |
|------------|------------------------------------|
| event      | Event causing the callback.        |
| reserved1  | Reserved for future use.           |
| rxBuff     | Received data buffer.              |
| rxLen      | Length of data in received buffer. |
| packet     | Pointer to packet being returned.  |
| deviceList | Pointer to discovery device list.  |
| status     | Status of stack.                   |
| reserved2  | Reserved for future use.           |

## IrStatsType Struct

**Purpose** The IrStatsType structure defines performance statistics for the IR Library. Use the [ExgControl\(\)](#) function with an irGetStatistics operation to retrieve these statistics. See [IR Control Constants](#) for more information.

**Prototype**

```
typedef struct {
    UInt16 recLineErrors;
    UInt16 crcErrors;
} IrStatsType;
```

### Field Descriptions

**recLineErrors** The number of serial errors since the library opened.

**crcErrors** The number of CRC errors since the library opened.

## IR Library Constants

### IR Control Constants

The IR control constants define operations that the IR Exchange Library can perform. You pass these constants as the operation parameter to [ExgControl\(\)](#). The following table lists the operation constants, the data that should be passed as the *valueP* parameter to *ExgControl*, and what operation is performed in response.

| Operation Constant             | value Data Type                            | Description                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irGetScanningMode</code> | Boolean. Output only.                      | Returns true in <i>*valueP</i> if beaming is enabled or false if beaming is disabled.                                                                                                                      |
| <code>irGetStatistics</code>   | <a href="#">IrStatsType</a> . Output only. | Returns performance statistics.                                                                                                                                                                            |
| <code>irRestoreScanning</code> | None                                       | Re-enables beaming after an <code>irSuppressScanning</code> operation. This operation keeps track of the number of requests that beaming be disabled and re-enables beaming only when the count reaches 0. |

| Operation Constant             | value Data Type                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                                                                                                                        | <p>This operation differs from <code>irSetScanningMode</code> in that it does not update the saved preferences.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>irSetScanningMode</code> | Boolean. Input only.                                                                                                   | <p>Enables or disables beaming.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                |                                                                                                                        | <p>This operation modifies the saved preferences database, which is back up during a HotSync<sup>®</sup> operation. Because of this, beaming may remain disabled after a reset if you use this operation to disable it. If you want to temporarily disable beaming use <code>irSuppressScanning</code> and <code>irRestoreScanning</code> instead.</p>                                                                                                                                                                                                                                                                           |
| <code>irSetBaudMask</code>     | UInt16 containing a mask of the <code>irOpenOptSpeed...</code> constants defined in <code>IrLib.h</code> . Input only. | <p>Sets the possible baud rates that the IR Library will use to those specified in <code>*valueP</code>. OR the <code>irOpenOptSpeed...</code> constants together to specify more than one. The default rate is 0, which causes the baud rate to be determined by the hardware.</p> <p>This operation is sometimes useful for debugging connections. Generally, you should set all bits up to the fastest rate you want to allow. To reset, use this operation again and pass 0 in <code>*valueP</code>.</p> <p>If you change the baud rate, your changes are until the device is reset or you perform this operation again.</p> |

| Operation Constant              | value Data Type      | Description                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irSetSerialMode</code>    | Boolean. Input only. | If the specified value is <code>true</code> , the IR Library uses the serial port instead of the infrared port until the device is reset. This option is useful for debugging. You can run your application in POSE and use the IR Library to communicate with a device connected in the cradle.                                           |
| <code>irSetSupported</code>     | Boolean. Input only. | If <code>true</code> , IR is supported on this device. If <code>false</code> , IR is not supported. You can use this constant to disable the unsupported dialog that normally displays when a beam is attempted and no IR support is available.                                                                                            |
| <code>irSuppressScanning</code> | None                 | <p>Temporarily disables beam receive. This operation keeps track of the number of requests that beaming be disabled and re-enables beaming (through <code>irRestoreScanning</code>) only when the count reaches 0.</p> <p>This operation differs from <code>irSetScanningMode</code> in that it does not update the saved preferences.</p> |

## IR Stack Callback Events

The IR stack calls the application by way of a callback function stored in each [IrConnect](#) structure. The callback function is called with a pointer to the `IrConnect` structure and a pointer to a parameter structure. The parameter structure contains an event field, which indicates the reason the callback is called, and other parameters, which have meaning based on the event.

The meaning of the events is described in the following sections.

## **LEVENT\_DATA\_IND**

Data has been received. The received data is accessed using fields `rxBuff` and `rxLen`.

## **LEVENT\_DISCOVERY\_CNF**

Indicates the completion of a discovery operation. The field `deviceList` points to the discovery list.

## **LEVENT\_LAP\_CON\_CNF**

The requested IrLAP connection has been made successfully. The callback function of all bound `IrConnect` structures is called.

## **LEVENT\_LAP\_CON\_IND**

Indicates that the IrLAP connection has come up. The callback of all bound `IrConnect` structures is called.

## **LEVENT\_LAP\_DISCON\_IND**

Indicates that the IrLAP connection has gone down. This means that all IrLMP connections are also down. A callback with event `LEVENT_LM_CON_IND` is not given. The callback function of all bound `IrConnect` structures is called.

## **LEVENT\_LM\_CON\_CNF**

The requested IrLMP/Tiny TP connection has been made successfully. Connection data from the other side is found using fields `rxBuff` and `rxLen`.

## **LEVENT\_LM\_CON\_IND**

Other device has initiated a connection. `IrConnectRsp` should be called to accept the connection. Any data associated with the connection request can be found using fields `rxBuff` and `rxLen`, data pointer and length, respectively.

## **LEVENT\_LM\_DISCON\_IND**

The IrLMP/Tiny TP connection has been disconnected. Any data associated with the disconnect indication can be found using fields `rxBuff` and `rxLen`, data pointer and length, respectively.

## **LEVENT\_PACKET\_HANDLED**

A packet is being returned. A pointer to the packet exists in field `packet`.

## **LEVENT\_STATUS\_IND**

Indicates that a status event from the stack has occurred. The `status` field indicates the status generating the event. Possible status values are as follows:

- `IR_STATUS_NO_PROGRESS` which means that IrLAP has no progress for 3 seconds threshold time (for example, the beam is blocked).
- `IR_STATUS_LINK_OK` which indicates that the no progress condition has cleared.
- `IR_STATUS_MEDIA_NOT_BUSY` which indicates that the IR media has transitioned from busy to not busy.

## **LEVENT\_TEST\_CNF**

Indicates that a TEST command has completed. The `status` field indicates if the test was successful.

- `IR_STATUS_SUCCESS` indicates that the operation was successful and the data in the test response can be found by using the `rxBuff` and `rxLen` fields.
- `IR_STATUS_FAILED` indicates that no TEST response was received. The packet passed to perform the test command is passed back in the `packet` field and is now available (no separate packet handled event occurs).

## LEVENT\_TEST\_IND

Indicates that a TEST command frame has been received. A pointer to the received data is in `rxBuff` and `rxLen`. A pointer to the packet that is sent in response to the test command is in the `packet` field. The packet is currently set up to respond with the same data sent in the command TEST frame. If different data is desired as a response, then you need to modify the packet structure. This event is sent to the callback function in all bound `IrConnect` structures. The IAS connections ignore this event.

## IR Library Functions

### IrAdvanceCredit Function

|                    |                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Advances the credit to the other side of the connection.                                                                                                                                            |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                |
| <b>Prototype</b>   | <code>void IrAdvanceCredit (IrConnect* con,<br/>                        UInt8 credit)</code>                                                                                                        |
| <b>Parameters</b>  | <div>→ <i>con</i><br/>    Pointer to <a href="#">IrConnect</a> structure representing connection to which credit is advanced.</div> <div>→ <i>credit</i><br/>    Amount of credit to advance.</div> |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                    |

- Comments** The credit passed by this function is added to the existing available credit, which must not exceed 127. This function only makes sense for a Tiny TP connection.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrBind Function

- Purpose** Obtains a local LSAP selector and registers the connection with the protocol stack.
- Declared In** `IrLib.h`
- Prototype**  
`IrStatus IrBind (UInt16 refNum, IrConnect* con, IrCallback callBack)`
- Parameters**
- *refnum*  
IR library refNum.
  - ↔ *con*  
Pointer to [IrConnect](#) structure.
  - *callBack*  
Pointer to a callBack function that handles the indications and confirmation from the protocol stack.
- Returns** `IR_STATUS_SUCCESS` means the operation completed successfully. The assigned LSAP can be found in `con->lLsap`.
- `IR_STATUS_FAILED` means the operation failed for one of the following reasons:
- `con` is already bound to the stack.
  - There is no room in the connection table.
- Comments** The `IrConnect` structure is re-initialized. Any values stored in the structure are lost. The assigned LSAP is returned in the `lLsap` field of `con`. The type of the connection is set to `IrLMP`. The `IrConnect` must be bound to the stack before it can be used.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrClose Function

|                      |                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Closes the IR library. This releases the global memory for the IR stack and any system resources it uses. This must be called when an application is done with the IR library. |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                           |
| <b>Prototype</b>     | <code>Err IrClose (UInt16 refnum)</code>                                                                                                                                       |
| <b>Parameters</b>    | $\rightarrow$ <i>refnum</i><br>IR library refNum.                                                                                                                              |
| <b>Returns</b>       | Returns 0 if successful.                                                                                                                                                       |
| <b>Comments</b>      | Do not call this function unless the call to <a href="#">IrOpen()</a> was successful.                                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                            |

## IrConnectIrLap Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Starts an IrLAP connection.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>IrStatus IrConnectIrLap (UInt16 refNum,<br/>IrDeviceAddr deviceAddr)</code>                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | $\rightarrow$ <i>refnum</i><br>IR library refNum.<br>$\rightarrow$ <i>deviceAddr</i><br>32-bit address of device to which connection should be made.                                                                                                                                                                                                                                                                                                        |
| <b>Returns</b>     | <code>IR_STATUS_PENDING</code> means the operation started successfully; the result is returned by way of a callback.<br><code>IR_STATUS_MEDIA_BUSY</code> means the operation failed because the media is busy. Media busy is caused by one of the following reasons: <ul style="list-style-type: none"><li>• Other devices are using the IR medium.</li><li>• An IrLAP connection already exists.</li><li>• A discovery process is in progress.</li></ul> |
| <b>Comments</b>    | The result is signaled to all bound <code>IrConnect</code> structures by way of the callback function. The callback event is <code>LEVENT_LAP_CON_CNF</code> if successful or <code>LEVENT_LAP_DISCON_IND</code> if unsuccessful.                                                                                                                                                                                                                           |

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## IrConnectReq Function

- Purpose**            Requests an IrLMP or Tiny TP connection.
- Declared In**      `IrLib.h`
- Prototype**        `IrStatus IrConnectReq (UInt16 refNum,  
                         IrConnect* con, IrPacket* packet,  
                         UInt8 credit)`
- Parameters**
- *refnum*  
    IR library refNum.
  - *con*  
    Pointer to [IrConnect](#) structure for handling the connection. The `rLsap` field must contain the LSAP selector for the peer on the other device. Also the type of the connection must be set. Use `IR_SetConTypeLMP` to set the type to an IrLMP connection or `IR_SetConTypeTTP` to set the type to a Tiny TP connection.
  - *packet*  
    Pointer to a packet that contains connection data. Even if no connection data is needed, the packet must point to a valid [IrPacket](#) structure. The packet is returned by way of the callback function with the `LEVENT_PACKET_HANDLED` event if no errors occur. The maximum size of the packet is `IR_MAX_CON_PACKET` for an IrLMP connection or `IR_MAX_TTP_CON_PACKET` for a Tiny TP connection.
  - *credit*  
    Initial amount of credit advanced to the other side. Must be less than 127. It is ANDed with 0x7f, so if it is greater than 127, unexpected results occur. This parameter is ignored if the connection is an IrLMP connection.
- Returns**            `IR_STATUS_PENDING` means the operation has been started successfully and the result is returned by way of the callback function with the event `LEVENT_LM_CON_CNF` if the connection is made or `LEVENT_LM_DISCON_IND` if connection fails. The packet is returned by way of the callback with the event `LEVENT_PACKET_HANDLED`.

IR\_STATUS\_FAILED means the operation failed because of one of the following reasons. Note that the packet is available immediately.

- The connection is busy (already involved in a connection).
- The IrConnect structure is not bound to the stack.
- The packet size exceeds maximum allowed.

IR\_STATUS\_NO\_IRLAP means the operation failed because there is no IrLAP connection (the packet is available immediately).

**Comments** The result is signaled by way of the callback specified in the IrConnect structure. The callback event LEVENT\_LM\_CON\_CNF indicates that the connection is up and LEVENT\_LM\_DISCON\_IND indicates that the connection failed. Before calling this function the fields in the con structure must be properly set.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrConnectRsp Function

**Purpose** Accepts an incoming connection that has been signaled by way of the callback with the event LEVENT\_LM\_CON\_IND.

**Declared In** IrLib.h

**Prototype** IrStatus IrConnectRsp (UInt16 refNum,  
IrConnect\* con, IrPacket\* packet,  
UInt8 credit)

**Parameters** → *refnum*  
IR library refNum.

→ *con*  
Pointer to [IrConnect](#) structure.

→ *packet*  
Pointer to a packet that contains connection data. Even if no connection data is needed, the packet must point to a valid [IrPacket](#) structure. The packet is returned by way of the callback with the LEVENT\_PACKET\_HANDLED event if no errors occur. The maximum size of the packet is IR\_MAX\_CON\_PACKET for an IrLMP connection or IR\_MAX\_TTP\_CON\_PACKET for a Tiny TP connection.

→ *credit*

Initial amount of credit advanced to the other side. Must be less than 127. It is ANDed with 0x7f, so if it is greater than 127, unexpected results occur. This parameter is ignored if the connection is an IrLMP connection.

**Returns** IR\_STATUS\_PENDING means the operation has been started successfully and the packet is returned by way of the callback function with the event LEVENT\_PACKET\_HANDLED.

IR\_STATUS\_FAILED means the operation failed because of one of the following reasons. Note that the packet is available immediately.

- The connection is not in the proper state to require a response.
- The IrConnect structure is not bound to the stack.
- The packet size exceeds the maximum allowed.

IR\_STATUS\_NO\_IRLAP means the operation failed because there is no IrLAP connection (the packet is available immediately).

**Comments** IrConnectRsp can be called during the callback or later to accept the connection. The type of the connection must already have been set to IrLMP or Tiny TP before the LEVENT\_LM\_CON\_IND event.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrDataReq Function

**Purpose** Sends a data packet.

**Declared In** IrLib.h

**Prototype** IrStatus IrDataReq (UInt16 refNum, IrConnect\* con, IrPacket\* packet)

**Parameters**

→ *refnum*  
IR library refNum.

→ *con*  
Pointer to [IrConnect](#) structure that specifies the connection over which the packet should be sent.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>→ <i>packet</i></p> <p>Pointer to a valid <a href="#">IrPacket</a> structure that contains data to send. The packet should not exceed the maximum size found with <a href="#">IrMaxTxSize()</a>.</p>                                                                                                                                                                                                                                                                                                                                       |
| <b>Returns</b>       | <p>IR_STATUS_PENDING means the packet has been queued by the stack. The packet is returned by way of the callback with event LEVENT_PACKET_HANDLED.</p> <p>IR_STATUS_FAILED means the operation failed because of one of the following reasons. Note that the packet is available immediately.</p> <ul style="list-style-type: none"> <li>• The IrConnect structure is not bound to the stack.</li> <li>• The packet size exceeds the maximum allowed.</li> <li>• The IrConnect structure does not represent an active connection.</li> </ul> |
| <b>Comments</b>      | <p>The packet is owned by the stack until it is returned by way of the callback with event LEVENT_PACKET_HANDLED. The largest packet that can be sent is found by calling <a href="#">IrMaxTxSize()</a>.</p>                                                                                                                                                                                                                                                                                                                                  |
| <b>Compatibility</b> | <p>Implemented only if <a href="#">3.0 New Feature Set</a> is present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## IrDisconnectIrLap Function

|                      |                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | <p>Disconnects an IrLAP connection.</p>                                                                                                                                                                                      |
| <b>Declared In</b>   | <p>IrLib.h</p>                                                                                                                                                                                                               |
| <b>Prototype</b>     | <p>IrStatus IrDisconnectIrLap (UInt16 refNum)</p>                                                                                                                                                                            |
| <b>Parameters</b>    | <p>→ <i>refnum</i></p> <p>IR library refNum.</p>                                                                                                                                                                             |
| <b>Returns</b>       | <p>IR_STATUS_PENDING means the operation started successfully and all bound IrConnect structures are called back when complete.</p> <p>IR_STATUS_NO_IRLAP means the operation failed because no IrLAP connection exists.</p> |
| <b>Comments</b>      | <p>When the IrLAP connection goes down, the callback of all bound IrConnect structures is called with event LEVENT_LAP_DISCON_IND.</p>                                                                                       |
| <b>Compatibility</b> | <p>Implemented only if <a href="#">3.0 New Feature Set</a> is present.</p>                                                                                                                                                   |

## **IrDiscoverReq Function**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Starts an IrLMP discovery process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | <code>IrStatus IrDiscoverReq (UInt16 refNum,<br/>IrConnect* con)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | <p>→ <i>refnum</i><br/>IR library refNum.</p> <p>→ <i>con</i><br/>Pointer to a bound <a href="#">IrConnect</a> structure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Returns</b>       | <p><code>IR_STATUS_PENDING</code> means the operation is started successfully; the result is returned by way of callback.</p> <p><code>IR_STATUS_MEDIA_BUSY</code> means the operation failed because the media is busy. Media busy is caused by one of the following reasons:</p> <ul style="list-style-type: none"><li>• Other devices are using the IR medium.</li><li>• A discovery process is already in progress.</li><li>• An IrLAP connection exists.</li></ul> <p><code>IR_STATUS_FAILED</code> means the operation failed because the <code>IrConnect</code> structure is not bound to the stack.</p> |
| <b>Comments</b>      | The result is signaled by way of the callback function specified in the <code>IrConnect</code> structure with the event <code>LEVENT_DISCOVERY_CNF</code> . Only one discovery can be invoked at a time.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## **IrIsIrLapConnected Function**

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Purpose</b>     | Determines if an IrLAP connection exists.                              |
| <b>Declared In</b> | <code>IrLib.h</code>                                                   |
| <b>Prototype</b>   | <code>BOOL IrIsIrLapConnected (UInt16 refNum)</code>                   |
| <b>Parameters</b>  | <p>→ <i>refnum</i><br/>IR library refNum.</p>                          |
| <b>Returns</b>     | <code>true</code> if IrLAP is connected, <code>false</code> otherwise. |

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Comments</b>      | Only available if <code>IR_IS_LAP_FUNCS</code> is defined.          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present. |

## **IrIsMediaBusy Function**

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Purpose</b>       | Determines if the IR media is busy.                                 |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                |
| <b>Prototype</b>     | <code>BOOL IrIsMediaBusy (UInt16 refNum)</code>                     |
| <b>Parameters</b>    | $\rightarrow$ <i>refnum</i><br>IR library refNum.                   |
| <b>Returns</b>       | true if IR media is busy, false otherwise.                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present. |

## **IrIsNoProgress Function**

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <b>Purpose</b>       | Determines if IrLAP is not making progress.                         |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                |
| <b>Prototype</b>     | <code>BOOL IrIsNoProgress (UInt16 refNum)</code>                    |
| <b>Parameters</b>    | $\rightarrow$ <i>refnum</i><br>IR library refNum.                   |
| <b>Returns</b>       | ture if IrLAP is not making progress, false otherwise.              |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present. |

## **IrIsRemoteBusy Function**

|                    |                                                             |
|--------------------|-------------------------------------------------------------|
| <b>Purpose</b>     | Determines if IrLAP of the other device is busy.            |
| <b>Declared In</b> | <code>IrLib.h</code>                                        |
| <b>Prototype</b>   | <code>BOOL IrIsRemoteBusy (UInt16 refNum)</code>            |
| <b>Parameters</b>  | $\rightarrow$ <i>refnum</i><br>IR library refNum.           |
| <b>Returns</b>     | ture if IrLAP of the other device is busy, false otherwise. |

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrLocalBusy Function**

**Purpose**            Sets the IrLAP local busy flag.

**Declared In**      `IrLib.h`

**Prototype**        `void IrLocalBusy (UInt16 refNum, BOOL flag)`

**Parameters**       `→ refnum`  
                      IR library refNum.

`→ flag`  
                      Value (`true` or `false`) to set for local busy flag of IrLAP.

**Returns**           Returns nothing.

**Comments**        If local busy is set to `true`, then the local IrLAP layer sends RNR (Receive Not Ready) frames to the other side indicating it cannot receive any more data. If the local busy is set to `false`, IrLAP is ready to receive frames.

                      The setting takes effect the next time IrLAP sends an RR (Receive Ready) frame. If IrLAP has data to send, the data is sent first, so it should be used carefully.

                      This function should not be used when using Tiny TP or when multiple connections exist.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrMaxRxSize Function**

**Purpose**            Returns the maximum size buffer that can be sent by the other device.

**Declared In**      `IrLib.h`

**Prototype**        `UInt16 IrMaxRxSize (UInt16 refNum, IrConnect* con)`

**Parameters**       `→ refnum`  
                      IR library refNum.

|                      |                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | → <i>con</i><br>Pointer to <a href="#">IrConnect</a> structure that represents an active connection.                                                                                                                                                                                            |
| <b>Returns</b>       | Returns the maximum size buffer that can be sent by the other device (maximum bytes that can be received). The value returned is only valid for active connections. The maximum size varies for each connection and is based on the negotiated IrLAP parameters and the type of the connection. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                             |

## IrMaxTxSize Function

|                      |                                                                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Returns the maximum size allowed for a transmit packet.                                                                                                                                                                                      |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                                                                                         |
| <b>Prototype</b>     | <code>UInt16 IrMaxTxSize (UInt16 refNum, IrConnect* con)</code>                                                                                                                                                                              |
| <b>Parameters</b>    | → <i>refnum</i><br>IR library refNum.<br><br>→ <i>con</i><br>Pointer to <a href="#">IrConnect</a> structure that represents an active connection.                                                                                            |
| <b>Returns</b>       | Returns the maximum size allowed for a transmit packet. The value returned is only valid for active connections. The maximum size varies for each connection and is based on the negotiated IrLAP parameters and the type of the connection. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                          |

## **IrOpen Function**

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                          |                                   |                                      |                                  |                                               |                                 |                  |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|--------------------------------------|----------------------------------|-----------------------------------------------|---------------------------------|------------------|
| <b>Purpose</b>                    | Opens the IR library. This allocates the global memory for the IR stack and reserves the system resources it requires. This must be done before any other IR library calls are made.                                                                                                                                                                                                                                     |                                   |                                      |                                  |                                               |                                 |                  |
| <b>Declared In</b>                | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                     |                                   |                                      |                                  |                                               |                                 |                  |
| <b>Prototype</b>                  | <code>Err IrOpen (UInt16 refnum, UInt32 options)</code>                                                                                                                                                                                                                                                                                                                                                                  |                                   |                                      |                                  |                                               |                                 |                  |
| <b>Parameters</b>                 | <p>→ <i>refnum</i><br/>IR library refNum. This value is returned from the function <a href="#">SysLibFind()</a>, which you must call first to load the IR library.</p> <p>→ <i>options</i><br/>Open options flags. See the Comments section for details.</p>                                                                                                                                                             |                                   |                                      |                                  |                                               |                                 |                  |
| <b>Returns</b>                    | Returns 0 if successful.                                                                                                                                                                                                                                                                                                                                                                                                 |                                   |                                      |                                  |                                               |                                 |                  |
| <b>Comments</b>                   | <p>The following flags can be specified for the <code>options</code> parameter to set the speed of the connection:</p> <table><tr><td><code>irOpenOptSpeed115200</code></td><td>Set to maximum negotiated baud rate.</td></tr><tr><td><code>irOpenOptSpeed57600</code></td><td>Set to 57600 bps (default if no flags given).</td></tr><tr><td><code>irOpenOptSpeed9600</code></td><td>Set to 9600 bps.</td></tr></table> | <code>irOpenOptSpeed115200</code> | Set to maximum negotiated baud rate. | <code>irOpenOptSpeed57600</code> | Set to 57600 bps (default if no flags given). | <code>irOpenOptSpeed9600</code> | Set to 9600 bps. |
| <code>irOpenOptSpeed115200</code> | Set to maximum negotiated baud rate.                                                                                                                                                                                                                                                                                                                                                                                     |                                   |                                      |                                  |                                               |                                 |                  |
| <code>irOpenOptSpeed57600</code>  | Set to 57600 bps (default if no flags given).                                                                                                                                                                                                                                                                                                                                                                            |                                   |                                      |                                  |                                               |                                 |                  |

## **IrSetConTypeLMP Function**

|                      |                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Sets the type of the connection to IrLMP. This function must be called after the <code>IrConnect</code> structure is bound to the stack. |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                     |
| <b>Prototype</b>     | <code>void IrSetConTypeLMP (IrConnect* con)</code>                                                                                       |
| <b>Parameters</b>    | <p>→ <i>con</i><br/>Pointer to <a href="#">IrConnect</a> structure.</p>                                                                  |
| <b>Returns</b>       | Returns nothing.                                                                                                                         |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                      |

## IrSetConTypeTTP Function

|                      |                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Sets the type of the connection to Tiny TP. This function must be called after the <code>IrConnect</code> structure is bound to the stack. |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                       |
| <b>Prototype</b>     | <code>void IrSetConTypeTTP (IrConnect* con)</code>                                                                                         |
| <b>Parameters</b>    | → <i>con</i><br>Pointer to <a href="#">IrConnect</a> structure.                                                                            |
| <b>Returns</b>       | Returns nothing.                                                                                                                           |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                        |

## IrSetDeviceInfo Function

|                      |                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Sets the XID info string used during discovery to the given string and length.                                                                                    |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                              |
| <b>Prototype</b>     | <code>IrStatus IrSetDeviceInfo (UInt16 refNum,<br/>                          UInt8 *info, UInt8 len)</code>                                                       |
| <b>Parameters</b>    | → <i>refnum</i><br>IR library refNum.<br><br>→ <i>info</i><br>Pointer to array of bytes.<br><br>→ <i>len</i><br>Number of bytes pointed to by <i>info</i> .       |
| <b>Returns</b>       | <code>IR_STATUS_SUCCESS</code> means the operation is successful.<br><br><code>IR_STATUS_FAILED</code> means the operation failed because <i>info</i> is too big. |
| <b>Comments</b>      | The XID <i>info</i> string contains hints and the nickname of the device. The size cannot exceed <code>IR_MAX_DEVICE_INFO</code> bytes.                           |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                               |

## **IrTestReq Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Requests a TEST command frame be sent in the NDM (Normal Disconnect Mode) state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>IrStatus IrTestReq (UInt16 refNum,<br/>                    IrDeviceAddr devAddr, IrConnect* con,<br/>                    IrPacket* packet)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p>→ <i>refnum</i><br/>IR library refNum.</p> <p>→ <i>devAddr</i><br/>Address of device where TEST is sent. This address is not checked so it can be the broadcast address or 0.</p> <p>→ <i>con</i><br/>Pointer to <a href="#">IrConnect</a> structure specifying the callback function to call to report the result.</p> <p>→ <i>packet</i><br/>Pointer to an <a href="#">IrPacket</a> structure that contains the data to send in the TEST command packet. The maximum size data that can be sent is <code>IR_MAX_TEST_PACKET</code>. Even if no data is to be sent, a valid packet must be passed.</p>                                                                                                                                                   |
| <b>Returns</b>     | <p><code>IR_STATUS_PENDING</code> means the operation has been started successfully and the result is returned by way of the callback function with the event <code>LEVENT_TEST_CNF</code>. This is also the indication returning the packet.</p> <p><code>IR_STATUS_FAILED</code> means the operation failed because of one of the following reasons. Note that the packet is available immediately.</p> <ul style="list-style-type: none"><li>• The <code>IrConnect</code> structure is not bound to the stack.</li><li>• The packet size exceeds the maximum allowed.</li></ul> <p><code>IR_STATUS_MEDIA_BUSY</code> means the operation failed because the media is busy or the stack is not in the NDM state (the packet is available immediately).</p> |
| <b>Comments</b>    | <p>The result is signaled by way of the callback specified in the <code>IrConnect</code> structure. The callback event is <code>LEVENT_TEST_CNF</code> and the status field indicates the result of the operation.</p> <p><code>IR_STATUS_SUCCESS</code> indicates success and <code>IR_STATUS_FAILED</code> indicates no response was received. A packet must be passed</p>                                                                                                                                                                                                                                                                                                                                                                                 |

containing the data to send in the TEST frame. The packet is returned when the LEVENT\_TEST\_CNF event is given.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## IrUnbind Function

**Purpose**    Unbinds the IrConnect structure from the protocol stack, freeing its LSAP selector.

**Declared In**    IrLib.h

**Prototype**    IrStatus IrUnbind (UInt16 refNum, IrConnect\* con)

**Parameters**    → *refnum*

IR library refNum.

→ *con*

Pointer to [IrConnect](#) structure to unbind.

**Returns**    IR\_STATUS\_SUCCESS means the operation completed successfully.

IR\_STATUS\_FAILED means the operation failed for one of the following reasons:

- The IrConnect structure was not bound.
- The lLsap field contained an invalid number.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## IAS Functions and Macros

This section describes the following functions and macros related to IAS database:

- [IrIAS\\_Add\(\)](#)
- [IrIAS\\_GetInteger\(\)](#)
- [IrIAS\\_GetIntLsap\(\)](#)
- [IrIAS\\_GetObjectID\(\)](#)
- [IrIAS\\_GetOctetString\(\)](#)
- [IrIAS\\_GetOctetStringLength\(\)](#)
- [IrIAS\\_GetType\(\)](#)

- [IrIAS\\_GetUserString\(\)](#)
- [IrIAS\\_GetUserStringCharSet\(\)](#)
- [IrIAS\\_GetUserStringLen\(\)](#)
- [IrIAS\\_Next\(\)](#)
- [IrIAS\\_Query\(\)](#)
- [IrIAS\\_SetDeviceName\(\)](#)
- [IrIAS\\_StartResult\(\)](#)

## **IrIAS\_Add Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Adds an IAS object to the IAS Database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Prototype</b>   | <code>IrStatus IrIAS_Add (UInt16 refNum,<br/>IrIasObject* obj)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p>→ <i>refnum</i><br/>IR library refNum.</p> <p>→ <i>obj</i><br/>Pointer to an <a href="#"><u>IrIASObject</u></a> structure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Returns</b>     | <p><code>IR_STATUS_SUCCESS</code> means the operation is successful.</p> <p><code>IR_STATUS_FAILED</code> means the operation failed for one of the following reasons:</p> <ul style="list-style-type: none"><li>• There is no space in the database.</li><li>• An entry with the same class name already exists.</li><li>• The attributes of the object violate the IrDA Lite rules (attribute name exceeds <code>IR_MAX_IAS_NAME</code>, or attribute value exceeds <code>IR_MAX_IAS_ATTR_SIZE</code>).</li><li>• The class name exceeds <code>IR_MAX_IAS_NAME</code>.</li></ul> |
| <b>Comments</b>    | <p>The object is not copied, so the memory for the object must exist for as long as the object is in the database. The IAS database is designed to allow only objects with unique class names, and it checks for this. Class names and attributes names must not exceed <code>IR_MAX_IAS_NAME</code>. Also, attribute values must not exceed <code>IR_MAX_IAS_ATTR_SIZE</code>.</p>                                                                                                                                                                                                |

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrIAS\_GetInteger Macro

**Purpose** Return an integer value, assuming that the current result item is of type `IAS_ATTRIB_INTEGER`. (Call [IrIAS\\_GetType\(\)](#) to determine the type of the current result item.)

**Declared In** `IrLib.h`

**Prototype** `#define IrIAS_GetInteger (t)`

**Parameters** `→ t`  
Pointer to an [IrIasQuery](#) structure.

**Returns** Integer value returned as a `UInt32`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrIAS\_GetIntLsap Macro

**Purpose** Return an integer value that represents an LSAP, assuming that the current result item is of type `IAS_ATTRIB_INTEGER`. (Call [IrIAS\\_GetType\(\)](#) to determine the type of the current result item.) Usually integer values returned in a query are LSAP selectors.

**Declared In** `IrLib.h`

**Prototype** `#define IrIAS_GetIntLsap (t)`

**Parameters** `→ t`  
Pointer to an [IrIasQuery](#) structure.

**Returns** Integer value returned as a `UInt8`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_GetObjectID Macro**

|                      |                                                                         |
|----------------------|-------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the unique object ID of the current result item.                 |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                    |
| <b>Prototype</b>     | <code>#define IrIAS_GetObjectID (t)</code>                              |
| <b>Parameters</b>    | <code>→ t</code><br>Pointer to an <a href="#">IrIasQuery</a> structure. |
| <b>Returns</b>       | Returns the object ID as a <code>UInt16</code> type.                    |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.     |

## **IrIAS\_GetOctetString Macro**

|                      |                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return a pointer to an octet string, assuming that the current result item is of type <code>IAS_ATTRIB_OCTET_STRING</code> . (Call <a href="#">IrIAS_GetType()</a> to determine the type of the current result item.) |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                                                                  |
| <b>Prototype</b>     | <code>#define IrIAS_GetOctetString (t)</code>                                                                                                                                                                         |
| <b>Parameters</b>    | <code>→ t</code><br>Pointer to an <a href="#">IrIasQuery</a> structure.                                                                                                                                               |
| <b>Returns</b>       | Pointer to octet string of type <code>UInt8</code> .                                                                                                                                                                  |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                   |

## **IrIAS\_GetOctetStringLength Macro**

|                    |                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the length of an octet string, assuming that the current result item is of type <code>IAS_ATTRIB_OCTET_STRING</code> . (Call <a href="#">IrIAS_GetType()</a> to determine the type of the current result item.) |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                   |
| <b>Prototype</b>   | <code>#define IrIAS_GetOctetStringLength (t)</code>                                                                                                                                                                    |
| <b>Parameters</b>  | <code>→ t</code><br>Pointer to an <a href="#">IrIasQuery</a> structure.                                                                                                                                                |
| <b>Returns</b>     | Length of octet string returned as a <code>UInt16</code> .                                                                                                                                                             |

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

### **IrIAS\_GetType Macro**

**Purpose**            Return the type of the current result item.

**Declared In**      `IrLib.h`

**Prototype**        `#define IrIAS_GetType (t)`

**Parameters**       `→ t`  
                     Pointer to an [IrIasQuery](#) structure.

**Returns**           Type of result item, such as `IAS_ATTRIB_INTEGER`,  
`IAS_ATTRIB_OCTET_STRING` or `IAS_ATTRIB_USER_STRING`.  
The return value is of type `UInt8`.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

### **IrIAS\_GetUserString Macro**

**Purpose**            Return a pointer to a user string, assuming that the current result item is of type `IAS_ATTRIB_USER_STRING`. (Call [IrIAS\\_GetType\(\)](#) to determine the type of the current result item.)

**Declared In**      `IrLib.h`

**Prototype**        `#define IrIAS_GetUserString (t)`

**Parameters**       `→ t`  
                     Pointer to an [IrIasQuery](#) structure.

**Returns**           Pointer to result string of type `UInt8`.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

### **IrIAS\_GetUserStringCharSet Macro**

**Purpose**            Return the character set of the user string, assuming that the current result item is of type `IAS_ATTRIB_USER_STRING`. (Call

[IrIAS\\_GetType\(\)](#) to determine the type of the current result item.)

**Declared In** `IrLib.h`

**Prototype** `#define IrIAS_GetUserStringCharSet (t)`

**Parameters** `→ t`  
Pointer to an [IrIasQuery](#) structure.

**Returns** Character set returned as an `IrCharSet` value.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_GetUserStringLen Macro**

**Purpose** Return the length of a user string, assuming that the current result item is of type `IAS_ATTRIB_USER_STRING`. (Call [IrIAS\\_GetType\(\)](#) to determine the type of the current result item.)

**Declared In** `IrLib.h`

**Prototype** `#define IrIAS_GetUserStringLen (t)`

**Parameters** `→ t`  
Pointer to an [IrIasQuery](#) structure.

**Returns** Length of user string returned as a `UInt8` value.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_Next Function**

**Purpose** Moves the internal pointer to the next result item.

**Declared In** `IrLib.h`

**Prototype** `UInt8* IrIAS_Next (UInt16 refNum,  
IrIasQuery* token)`

**Parameters** `→ refnum`  
IR library `refNum`.

`→ token`  
Pointer to an [IrIasQuery](#) structure.

**Returns** Pointer to the next result item, or 0 if there are no more items.

|                      |                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>      | This function returns a pointer to the start of the next result item. If the pointer is 0, then there are no more result items. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                             |

## **IrIAS\_Query Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Makes an IAS query of the IAS database of another device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>IrStatus IrIAS_Query (UInt16 refNum,<br/>    IrIasQuery* token)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>→ <i>refnum</i><br/>IR library refNum.</p> <p>→ <i>token</i><br/>Pointer to an <a href="#">IrIasQuery</a> structure initialized as described in the Comments section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Returns</b>     | <p><code>IR_STATUS_SUCCESS</code> means the operation is started successfully and the result is signaled by way of the callback function.</p> <p><code>IR_STATUS_FAILED</code> means the operation failed for one of the following reasons:</p> <ul style="list-style-type: none"><li>• The query exceeds <code>IR_MAX_QUERY_LEN</code>.</li><li>• The <code>result</code> field of <code>token</code> is 0.</li><li>• The <code>resultBufSize</code> field of <code>token</code> is 0.</li><li>• The <code>callback</code> field of <code>token</code> is 0.</li><li>• A query is already in progress.</li></ul> <p><code>IR_STATUS_NO_IRLAP</code> means the operation failed because there is no IrLAP connection.</p> |
| <b>Comments</b>    | <p>An IrLAP connection must exist to the other device. The IAS query token must be initialized as described below. The result is signaled by calling the callback function whose pointer exists in the <code>IrIasQuery</code> structure. Only one query can be made at a time.</p> <p>The <code>IrIasQuery</code> structure passed in the <code>token</code> parameter must be initialized as follows:</p>                                                                                                                                                                                                                                                                                                               |

- Assign a pointer to a callback function in which the result is signaled.
- Set `result` to point to a buffer large enough to hold the result of the query.
- Set `resultBufSize` to the size of the result buffer.
- Set `queryBuf` to point to a valid query.
- Set `queryLen` to the number of bytes in `queryBuf`. The length must not exceed `IR_MAX_QUERY_LEN`.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_SetDeviceName Function**

**Purpose**    Sets the value field of the device name attribute of the “Device” object in the IAS database.

**Declared In**    `IrLib.h`

**Prototype**    `IrStatus IrIAS_SetDeviceName (UInt16 refNum,  
                                          UInt8 *name, UInt8 len)`

**Parameters**     $\rightarrow$  *refnum*  
                    IR library refNum.

$\rightarrow$  *name*  
                    Pointer to an IAS value field for the device name attribute of the device object. It includes the attribute type, character set and device name. This value field should be a constant and the pointer must remain valid until `IrIAS_SetDeviceName` is called with another pointer.

$\rightarrow$  *len*  
                    Total length of the value field. Maximum size allowed is `IR_MAX_IAS_ATTR_SIZE`.

**Returns**    `IR_STATUS_SUCCESS` means the operation is successful.

`IR_STATUS_FAILED` means `len` is too big, or the value field is not a valid user string.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_StartResult Macro**

|                      |                                                                         |
|----------------------|-------------------------------------------------------------------------|
| <b>Purpose</b>       | Put the internal pointer to the start of the result buffer.             |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                    |
| <b>Prototype</b>     | <code>#define IrIAS_StartResult (t)</code>                              |
| <b>Parameters</b>    | <code>→ t</code><br>Pointer to an <a href="#">IrIasQuery</a> structure. |
| <b>Returns</b>       | Returns nothing.                                                        |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.     |

## **Application-Defined Functions**

The functions in this section are supplied by the developer and can be named anything.

## **IrIasQueryCallBack Function**

|                    |                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Signals the result of IAS query. The result of IAS queries is signaled by calling this callback function which is pointed to by the <code>callBack</code> field of the <a href="#">IrIasQuery</a> structure.                                                                                                                                                            |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <code>void IrIasQueryCallBack (IrStatus status)</code>                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <code>→ status</code><br>The status of the query operation. The following values can be passed:<br><br><code>IR_STATUS_SUCCESS</code><br>means the query operation finished successfully and the results can be parsed.<br><br><code>IR_STATUS_DISCONNECT</code><br>means the link or IrLMP connection was disconnected during the query, so the results are not valid. |
| <b>Returns</b>     | Returns nothing.                                                                                                                                                                                                                                                                                                                                                        |

# Modem Manager

---

This chapter provides reference material for the modem manager API. The header file `ModemMgr.h` declares the modem manager API.

## Modem Manager Functions

### MdmDial Function

|                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Initialize the modem, dial the phone number and wait for result.                                                                                                                                                                                                                                                                                                                                             |
| <b>Declared In</b> | <code>ModemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <pre>Err MdmDial (MdmInfoPtr modemP, Char *okDialP,              Char *userInitP, Char *phoneNumP)</pre>                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><code>modemP</code><br/>               Pointer to modem info structure (filled in by caller)</p> <p><code>okDialP</code><br/>               (NOT IMPLEMENTED) Pointer to string of chars allowed in dial string</p> <p><code>userInitP</code><br/>               Pointer to modem setup string without the AT prefix.</p> <p><code>phoneNumP</code><br/>               Pointer to phone number string</p> |
| <b>Returns</b>     | 0 if successful; otherwise <code>mdmErrNoTone</code> , <code>mdmErrNoDCD</code> , <code>mdmErrBusy</code> , <code>mdmErrUserCan</code> , <code>mdmErrCmdError</code>                                                                                                                                                                                                                                         |
| <b>Comments</b>    | <p>When executing this function, the system performs these steps:</p> <ul style="list-style-type: none"> <li>• Switch to the requested initial baud rate.</li> <li>• If HW hand-shake is requested, enable CTS/RTS hand-shaking; otherwise, disable it.</li> <li>• Reset the modem.</li> </ul>                                                                                                               |

## Modem Manager

### *MdmHangUp*

---

- Execute the setup string (if any).
- Configure the modem with required settings.
- Dial the phone number.
- Wait for CONNECT XXXXX or other response.
- If auto-baud is requested, switch to the connected baud rate.

## MdmHangUp Function

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Purpose</b>     | Hang up the modem.                                              |
| <b>Declared In</b> | ModemMgr.h                                                      |
| <b>Prototype</b>   | Err MdmHangUp (MdmInfoPtr modemP)                               |
| <b>Parameters</b>  | modemP<br>Pointer to modem info structure (filled in by caller) |
| <b>Returns</b>     | 0 if successful.                                                |

---

**WARNING!** This function alters configuration of the serial port (without restoring it).

---

# Net Library

---

This chapter describes the API available in the net library and its Berkeley sockets equivalents. The header file `NetMgr.h` declares the net library API. The chapter covers:

- [Net Library Data Structures](#)
- [Net Library Constants](#)
- [Net Library Functions](#)

For more information on the net library, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**IMPORTANT:** Applications cannot directly use the net library to make wireless connections. Use the `INetLib` for wireless connections.

---

## Net Library Data Structures

### NetConfigNameType Struct

|                      |                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | The <code>NetConfigNameType</code> structure defines a configuration name. A configuration is a specific set of values for the net library settings. Typically, users set up configurations and assign names to them using the Network preferences panel. |
| <b>Prototype</b>     | <pre>typedef struct {     Char name[netConfigNameSize]; } NetConfigNameType, NetConfigNamePtr;</pre> <p>name is the configuration’s name. The <code>netConfigNameSize</code> constant is currently defined to be 32.</p>                                  |
| <b>Compatibility</b> | Supported only if <a href="#">3.2 New Feature Set</a> is present.                                                                                                                                                                                         |

## NetHostInfoBufType Struct

**Purpose** The NetHostInfoBufType struct contains information about a host. The [NetHostInfoType](#) struct, which maps to the hostent struct, points to fields in this struct for its information.

**Prototype**

```
typedef struct {
    NetHostInfoType  hostInfo;
    Char             name [netDNSMaxDomainName+1];
    Char             *aliasList [netDNSMaxAliases+1];
    Char             aliases [netDNSMaxAliases
                             [netDNSMaxAliases+1];
    NetIPAddr        *addressList [netDNSMaxAddresses];
    NetIPAddr        address [netDNSMaxAddresses];
} NetHostInfoBufType, *NetHostInfoBufPtr;
```

### Field Descriptions

|             |                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------|
| hostInfo    | A <a href="#">NetHostInfoType</a> struct, which maps to the Berkeley UNIX sockets hostent structure. |
| name        | Official host name.                                                                                  |
| aliasList   | An array of aliases for the host name.                                                               |
| aliases     |                                                                                                      |
| addressList | An array of pointers to 32-bit IP addresses in                                                       |
| address     | host byte order.                                                                                     |

## NetHostInfoType Struct

**Purpose** The NetHostInfoType structure maps to the Berkeley UNIX sockets hostent structure. It is defined as follows:

**Prototype**

```
typedef struct {
    Char             *nameP;
    Char             **nameAliasesP;
    UInt16           addrType;
    UInt16           addrLen;
    UInt8            **addrListP;
} NetHostInfoType, *NetHostInfoPtr;
```

### Field Descriptions

|              |                                                                           |
|--------------|---------------------------------------------------------------------------|
| nameP        | Official host name.                                                       |
| nameAliasesP | An array of aliases for the host name.                                    |
| addrType     | The type of the return addresses. See <a href="#">NetSocketAddrEnum</a> . |
| addrLen      | The length in bytes of the return addresses.                              |
| addrListP    | An array of pointers to addresses in host byte order.                     |

## NetServInfoBufType Struct

**Purpose** The NetServInfoBufType struct contains information about a service. The [NetServInfoType](#) struct, which maps to the servent struct, points to fields in this struct for much of its information.

**Prototype**

```
struct {
    NetServInfoType servInfo;
    Char            name [netServMaxName+1] ;
    Char            *aliasList [netServMaxAliases+1] ;
    Char            aliases [netServMaxAliases]
[netServMaxName] ;
    Char            protoName [netProtoMaxName+1] ;
    UInt8          reserved;
} NetServInfoBufType, *NetServInfoBufPtr;
```

### Field Descriptions

|           |                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------|
| servInfo  | A <a href="#">NetServInfoType</a> struct, which maps to the Berkeley UNIX sockets servent structure. |
| name      | Official name of the service                                                                         |
| aliasList | Array of aliases for the service name.                                                               |
| aliases   |                                                                                                      |

|           |                              |
|-----------|------------------------------|
| protoName | Name of the protocol to use. |
| reserved  | Reserved for future use.     |

## NetServInfoType Struct

**Purpose** The NetServInfoType structure maps to the servent structure in Berkeley UNIX sockets API. It contains information about a service.

**Prototype**

```
struct {
    Char      *nameP;
    Char      **nameAliasesP;
    UInt16    port;
    Char      *protoP;
} NetServInfoType, *NetServInfoPtr;
```

### Field Descriptions

|              |                                        |
|--------------|----------------------------------------|
| nameP        | Official name of the service           |
| nameAliasesP | Array of aliases for the service name. |
| port         | Port number for the service.           |
| protoP       | Name of the protocol to use.           |

## NetSocketAddrEnum Enum

**Purpose** The NetSocketAddrEnum enum specifies the address types supported by the net library.

**Prototype**

```
typedef enum {
    netSocketAddrRaw = 0,
    netSocketAddrINET = 2
} NetSocketAddrEnum
```

### Value Descriptions

|                                |                                                            |
|--------------------------------|------------------------------------------------------------|
| <code>netSocketAddrRaw</code>  | Raw address. Supported in Palm OS® version 3.0 and higher. |
| <code>netSocketAddrINET</code> | IP address.                                                |

## NetSocketAddrINType Struct

**Purpose** The `NetSocketAddrINType` struct holds an internet socket address, that is, a socket that uses one of the internet protocols. This structure directly maps to the BSD UNIX `sockaddr_in` structure.

**Prototype**

```
typedef struct NetSocketAddrINType {
    Int16      family;
    UInt16     port;
    NetIPAddr  addr;
} NetSocketAddrINType;
```

### Field Descriptions

|                     |                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>family</code> | Address family in host byte order. This is either <code>netSocketAddrINET</code> or <code>netSocketAddrRaw</code> . |
| <code>port</code>   | The port in network byte order.                                                                                     |
| <code>addr</code>   | The IP address in network byte order.                                                                               |

## NetSocketAddrRawType Struct

**Purpose** The `NetSocketAddrRawType` structure holds a raw socket address.

**Prototype**

```
typedef struct NetSocketAddrRawType {
    Int16  family;
    UInt16 ifInstance;
    UInt32 ifCreator;
} NetSocketAddrRawType;
```

### Field Descriptions

|            |                                                                                          |
|------------|------------------------------------------------------------------------------------------|
| family     | Address family in host byte order. This is either netSocketAddrINET or netSocketAddrRaw. |
| ifInstance | The instance number of the interface that the socket uses to send and receive data.      |
| ifCreator  | The creator of the interface that the socket uses.                                       |

**Compatibility** Raw sockets are supported in Palm OS version 3.0 and higher.

## NetSocketAddrType Struct

**Purpose** The NetSocketAddrType structure holds a generic socket address. This struct can hold any type of address including Internet addresses. It directly maps to the BSD UNIX sockaddr structure.

Note that this structure is the same size as NetSocketAddrINType and NetSocketAddrRawType. This means that one of those two structures can be used for parameters declared to be NetSocketAddrType.

**Prototype**

```
typedef struct NetSocketAddrType {  
    Int16 family;  
    UInt8 data[14];  
} NetSocketAddrType;
```

## NetSocketRef Typedef

**Purpose** The NetSocketRef defines a socket descriptor. The socket descriptor is created and returned by [NetLibSocketOpen\(\)](#). It is used in any function that requires access to a socket.

**Prototype**    `typedef Int16 NetSocketRef`

## NetSocketTypeEnum Enum

**Purpose**    The NetSocketTypeEnum enum specifies the available socket types.

**Prototype**    `typedef enum {  
    netSocketTypeStream=1,  
    netSocketTypeDatagram=2,  
    netSocketTypeRaw=3,  
    netSocketTypeReliableMsg=4  
} NetSocketTypeEnum`

### Value Descriptions

|                                    |                                 |
|------------------------------------|---------------------------------|
| <code>netSocketTypeStream</code>   | Streams protocol over wireline. |
| <code>netSocketTypeDatagram</code> | UDP protocol.                   |
| <code>netSocketTypeRaw</code>      | Raw mode.                       |

## Net Library Constants

### Configuration Aliases

A configuration is a set of specific values for the net library settings. The net library defines a set of built-in configuration aliases for common network setups. These aliases point to configurations instead of holding the actual values themselves. You can specify an alias anywhere in the API you would specify a configuration.

The constants listed here specify the alias names. Most of the net library API requires a configuration index rather than a name. Use [NetLibConfigIndexFromName\(\)](#) to obtain the alias's index from the name.

|                                    |                                                        |
|------------------------------------|--------------------------------------------------------|
| <code>netCfgNameDefault</code>     | The default configuration.                             |
| <code>netCfgNameDefWireline</code> | The default configuration for wireline communications. |

|                                    |                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>netCfgNameDefWireless</code> | The default configuration for wireless communications.                                            |
| <code>netCfgNameCTPWireline</code> | The default configuration for wireline communications through the Palm Web Clipping Proxy server. |
| <code>netCfgNameCTPWireless</code> | The default configuration for wireless communications through the Palm Web Clipping Proxy server. |

By default, `netCfgNameDefault` points to the user's default configuration, and all other aliases point to `netCfgNameDefault` except for `netCfgNameCTPWireless`, which points to an private wireless configuration.

**Compatibility** Supported on version 3.2 and later.

## I/O Flags

The I/O flags specify special handling instructions to functions that send and receive data. You can OR these values together to specify more than one.

|                                 |                                                                 |
|---------------------------------|-----------------------------------------------------------------|
| <code>netIOFlagOutOfBand</code> | Process out-of-band data. Available for send calls only.        |
| <code>netIOFlagPeek</code>      | Peek at incoming message without dequeuing it.                  |
| <code>netIOFlagDontRoute</code> | Send without using routing. This constant is currently ignored. |

## Tracing Bits

The tracing bits are used to set the level of event tracing. An application can get a list of events in the trace buffer using the [`NetLibMaster\(\)`](#) call.

You can set the tracing for each network interface using [`NetLibIFSettingSet\(\)`](#) and for the net library in general with [`NetLibSettingSet\(\)`](#).

|                                |                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>netTracingErrors</code>  | Record run-time errors. This is the default.                                                                                                 |
| <code>netTracingMsgs</code>    | Record application trace messages.                                                                                                           |
| <code>netTracingPkts</code>    | Record packet I/O. This bit is obsolete in versions 3.2 and higher, but is mapped to <code>netTracingPktIP</code> .                          |
| <code>netTracingFuncs</code>   | Record function flow.                                                                                                                        |
| <code>netTracingAppMsgs</code> | Record application messages sent using <a href="#"><code>NetLibTracePrintf()</code></a> and <a href="#"><code>NetLibTracePutS()</code></a> . |
| <code>netTracingPktIP</code>   | Record packet I/O. If this set, the following five options are enabled.                                                                      |
| <code>netTracingData40</code>  | Record the first 40 bytes of each packet sent or received. This option is mutually exclusive with <code>netTracingData</code> .              |
| <code>netTracingData</code>    | Record the entirety of each packet sent or received. This option is mutually exclusive with <code>netTracingData40</code> .                  |
| <code>netTracingIFHi</code>    | Record packets sent or received at the highest layer of the network interface. This layer is just below the IP layer.                        |
| <code>netTracingIFMid</code>   | Record packets sent or received at the layer just below the highest layer of the network interface.                                          |
| <code>netTracingIFLow</code>   | Record packets sent or received at the lowest layer of the network interface.                                                                |

### Compatibility

The `netTracingPktXXX` constants are supported only in version 3.2 devices and higher. In previous versions, specify `netTracingPkts` instead; only the size of the packet is recorded.

## Net Library Functions

### NetHToNL Macro

|                           |                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>            | Converts a 32-bit value from host to network byte order.                                                                    |
| <b>Declared In</b>        | <code>NetBitUtils.h</code>                                                                                                  |
| <b>Prototype</b>          | <code>#define NetHToNL (x)</code>                                                                                           |
| <b>Parameters</b>         | <code>→ x</code><br>32-bit value to convert.                                                                                |
| <b>Returns</b>            | Returns <code>x</code> in network byte order.                                                                               |

## NetLibAddrAToIN Function

|                           |                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>            | Converts an ASCII string representing a dotted decimal IP address into a 32-bit IP address in network byte order.                |
| <b>Declared In</b>        | <code>NetMgr.h</code>                                                                                                            |
| <b>Prototype</b>          | <code>NetIPAddr NetLibAddrAToIN (UInt16 libRefnum,<br/>                              const Char *a)</code>                       |
| <b>Parameters</b>         | <p>→ <i>libRefNum</i><br/>Reference number of the net library.</p> <p>→ <i>a</i><br/>Pointer to ASCII dotted decimal string.</p> |
| <b>Returns</b>            | Returns a 32-bit network byte order IP address or -1 if it doesn't represent a dotted decimal IP address                         |
| <b>Sockets Equivalent</b> | <code>UInt32 inet_addr (char *cp)</code>                                                                                         |
| <b>See Also</b>           | <a href="#"><code>NetLibAddrINToA()</code></a>                                                                                   |

## NetLibAddrINToA Function

|                    |                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Converts an IP address from 32-bit network byte order into a dotted decimal ASCII string.                                                                                                             |
| <b>Declared In</b> | <code>NetMgr.h</code>                                                                                                                                                                                 |
| <b>Prototype</b>   | <code>Char *NetLibAddrINToA (UInt16 libRefnum,<br/>                          NetIPAddr inet, Char *spaceP)</code>                                                                                     |
| <b>Parameters</b>  | <p>→ <i>libRefNum</i><br/>Reference number of the net library.</p> <p>→ <i>inet</i><br/>32-bit IP address in network byte order.</p> <p>← <i>spaceP</i><br/>Buffer used to hold the return value.</p> |
| <b>Returns</b>     | Returns in <i>spaceP</i> the dotted decimal ASCII string representation of the IP address.                                                                                                            |

## Net Library

### *NetLibClose*

---

**Sockets  
Equivalent**

`char *inet_ntoa (struct in_addr in)`

**See Also**

[NetLibAddrAToIN\(\)](#)

## NetLibClose Function

**Purpose**

Closes the net library.

**Declared In**

`NetMgr.h`

**Prototype**

```
Err NetLibClose (UInt16 libRefnum,  
                UInt16 immediate)
```

**Parameters**

→ *libRefnum*

Reference number of the net library.

→ *immediate*

If `true`, library will shut down immediately. If `false`, library will shut down only if close timer expires before another [NetLibOpen\(\)](#) is issued.

**Returns**

Returns one of the following values:

0

Success.

`netErrNotOpen`

Library was not open.

`netErrStillOpen`

Not really an error; returned if library is still in use by another application.

**Sockets  
Equivalent**

None.

**Comments**

Applications must call this function when they no longer need the net library. If the net library open count is greater than 1 before this call is made, the count is decremented and `netErrStillOpen` is returned. If the open count was 1, the library takes the following action:

- If `immediate` is `true`, the library shuts down immediately. All network interfaces are brought down, the net protocol stack task is terminated, and all memory used by the net library is freed.

- If `immediate` is `false`, a close timer is created and this call returns immediately without actually bringing the net library down. Instead it leaves it up and running but marks it as in the “close-wait” state. It remains in this state until either the timer expires or another `NetLibOpen` is issued. If the timer expires, the library is shut down. If another `NetLibOpen` call is issued before the timer expires (possibly by another application), the timer is cancelled and the library is marked as fully open.

In most cases, you should pass `false` for `immediate`. This allows the user to quit one Internet application and launch another within a short period of time without having to wait through the process of closing down and then re-establishing dial-up network connections.

**See Also**    [`NetLibOpen\(\)`](#), [`NetLibOpenCount\(\)`](#)

## NetLibConfigAliasGet Function

**Purpose**    Return the configuration that an alias points to.

**Prototype**    `Err NetLibConfigAliasGet (UInt16 refNum,  
                                UInt16 aliasIndex, UInt16 *indexP,  
                                Boolean *isAnotherAliasP)`

**Parameters**     $\rightarrow$  *refNum*  
                    Reference number of the net library.

$\rightarrow$  *aliasIndex*  
                    Index of the alias.

$\leftarrow$  *indexP*  
                    Index of the configuration pointed to by the alias.

$\leftarrow$  *isAnotherAliasP*  
                    true if *indexP* is the index of another alias; false if  
                    *indexP* specifies an actual configuration.

**Returns**    Returns one of the following values:

                  0  
                    Success.

`netErrConfigNotAlias`  
                    The configuration at *aliasIndex* is not an alias.

`netErrOutOfCmdBlocks`

|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | <code>netErrParamErr</code><br>The specified index is out of range or there is no configuration at the index.                                                         |
| <b>Sockets Equivalent</b> | None                                                                                                                                                                  |
| <b>Comments</b>           | Use this routine to find out which configuration a built-in alias points to. See “ <a href="#">Configuration Aliases</a> ” for a description of the built-in aliases. |
| <b>Compatibility</b>      | Implemented only if <a href="#">3.2 New Feature Set</a> is present.                                                                                                   |
| <b>See Also</b>           | <a href="#">NetLibConfigAliasSet()</a>                                                                                                                                |

## NetLibConfigAliasSet Function

|                   |                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Set a built-in alias to point to a defined configuration.                                                                                                                                                                                                                       |
| <b>Prototype</b>  | <code>Err NetLibConfigAliasSet (UInt16 refNum,<br/>                          UInt16 configIndex, UInt16 aliasToIndex)</code>                                                                                                                                                    |
| <b>Parameters</b> | <p>→ <i>refNum</i><br/>Reference number of the net library.</p> <p>→ <i>configIndex</i><br/>Index of the built-in alias to be set.</p> <p>→ <i>aliasToIndex</i><br/>Index of the configuration to which the alias should point. You cannot set an alias to point to itself.</p> |
| <b>Returns</b>    | Returns one of the following values:                                                                                                                                                                                                                                            |
|                   | <code>0</code><br>Success.                                                                                                                                                                                                                                                      |
|                   | <code>netErrConfigCantPointToAlias</code><br>The configuration at <i>aliasToIndex</i> is an alias that points to an alias.                                                                                                                                                      |
|                   | <code>netErrConfigNotAlias</code><br>The configuration at <i>configIndex</i> isn’t an alias.                                                                                                                                                                                    |
|                   | <code>netErrOutOfCmdBlocks</code>                                                                                                                                                                                                                                               |

netErrParamErr

The specified index is out of range or there's no configuration at the index.

**Sockets  
Equivalent**

None

**Comments**

This function is used by the Network preferences panel when the user edits a configuration. Your application can use it to associate any of the built-in aliases with a defined configuration.

The built-in aliases are typically set up as shown in [Table 61.1](#). In this example, applications that specify a configuration index of 0 through 3 use a configuration that the user defines. Applications that use index 4 use a private configuration created by the network library.

**Table 61.1 Example Configuration Table**

| Index | Name         | Alias To |
|-------|--------------|----------|
| 0     | .Default     | 6        |
| 1     | .DefWireline | 0        |
| 2     | .DefWireless | 0        |
| 3     | .CTPWireline | 0        |
| 4     | .CTPWireless | 5        |
| 5     | _RAMCTP      |          |
| 6     | user-defined |          |

An alias can point to another alias so long as the nesting level is only one deep. That is, if you point an alias to an alias, you'll receive an error if that alias in turn points to another alias. This eliminates the possibility that an alias never resolves to an actual configuration.

**Compatibility**

Implemented only if [3.2 New Feature Set](#) is present.

## NetLibConfigIndexFromName Function

|                   |                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Obtain a configuration's index given its name.                                                                                                                    |
| <b>Prototype</b>  | <code>Err NetLibConfigIndexFromName (UInt16 refNum,<br/>                                  NetConfigNamePtr nameP, UInt16 *indexP)</code>                          |
| <b>Parameters</b> | <p>→ <i>refNum</i><br/>Reference number of the net library.</p> <p>→ <i>nameP</i><br/>Pointer to a configuration name. See <a href="#">NetConfigNameType</a>.</p> |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | $\leftarrow indexP$<br>The index of the configuration with the name *nameP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Returns</b>            | Returns one of the following values:<br>0<br>Success.<br>netErrConfigNotFound<br>A configuration with the specified name could not be found.<br>netErrOutOfCmdBlocks                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Sockets Equivalent</b> | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>           | This function returns the index of a configuration given its name. Your application should store the configuration's index rather than its name because a configuration's name can change.<br><br>If you pass the name of a built-in alias in nameP, this function returns the index of the alias's entry in the configuration table; it does not return the index that the alias points to. For example, if the alias netCfgNameCTPWireless is stored at index 4 and points to index 5, NetLibConfigIndexFromName returns 4. If you want to obtain the index that an alias points to, use <a href="#">NetLibConfigAliasGet()</a> . |
| <b>Compatibility</b>      | Implemented only if <a href="#">3.2 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>See Also</b>           | <a href="#">NetLibConfigList()</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## NetLibConfigList Function

|                   |                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>    | Return a list of net library configuration names.                                                                                                                         |
| <b>Prototype</b>  | <pre>Err NetLibConfigList (UInt16 refNum,     NetConfigNameType nameArray[],     UInt16 *arrayEntriesP)</pre>                                                             |
| <b>Parameters</b> | $\rightarrow refNum$<br>Reference number of the net library.<br><br>$\leftarrow nameArray$<br>The list of defined configurations. See <a href="#">NetConfigNameType</a> . |

↔ *arrayEntriesP*

On entry, contains the number of elements in *nameArray*.  
On return, contains the number of elements in *nameArray* that were actually used. The Net Library currently returns up to 16 entries. If the array is not large enough to hold all the configuration names, this function returns only as many names as the array can hold.

**Returns** Returns one of the following values:

0

Success.

*netErrOutOfCmdBlocks*

**Sockets  
Equivalent**

None

**Comments**

Use this function to obtain a list of the names of defined network configurations and configuration aliases.

Users create specific configurations using the Network preferences panel and associate names with each configuration. This function returns the list of defined configurations.

In addition to user-defined configurations, this function also returns built-in configuration aliases and private configurations. The built-in configuration aliases are described in "[Configuration Aliases](#)." Their actual names begin with a period (.). Private configurations have names that begin with an underscore (\_).

---

**IMPORTANT:** If you present the list returned by this function to your application's users, you must first filter out names beginning with a period or an underscore. These names are for internal use only.

---

Your application should refer to a configuration by its index rather than its name because the name can be changed. To obtain the configuration's index from its name, use [NetLibConfigIndexFromName\(\)](#).

**Compatibility**

Implemented only if [3.2 New Feature Set](#) is present.

## NetLibConfigMakeActive Function

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>            | Makes the specified configuration current without opening the net library.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>          | <code>Err NetLibConfigMakeActive (UInt16 refNum,<br/>                              UInt16 configIndex)</code>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>         | <p>→ <i>refNum</i><br/>Reference number of the net library.</p> <p>→ <i>configIndex</i><br/>Index of the configuration to use. An index of 0 refers to the default configuration as defined by the Network preferences panel.</p>                                                                                                                                                                                                                                                                                               |
| <b>Returns</b>            | <p>Returns one of the following values:</p> <p>0<br/>Success.</p> <p><code>netErrBufTooSmall</code><br/><code>netErrConfigAliasErr</code><br/><code>netErrConfigCantDelete</code><br/><code>netErrConfigEmpty</code><br/><code>netErrConfigNotFound</code><br/><code>netErrOutOfCmdBlocks</code><br/><code>netErrParamErr</code><br/><code>netErrPrefNotFound</code></p>                                                                                                                                                        |
| <b>Sockets Equivalent</b> | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>           | <p>This function is used mainly by the Network preferences panel when the user edits and saves network configurations. The Network preferences panel uses this function to make current the configuration the user wants to edit, set the settings appropriately, and then save the configuration using <a href="#">NetLibConfigSaveAs()</a>.</p> <p>Use this routine to make a specific configuration the current configuration without opening the net library. You should not use it if the net library is already open.</p> |

Unlike [NetLibOpenConfig\(\)](#), this routine does not save the current net library configuration so that it can be restored upon close.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

## NetLibConfigRename Function

**Purpose** Rename the specified configuration.

**Prototype** `Err NetLibConfigRename (UInt16 refNum,  
                                UInt16 index, NetConfigNamePtr newNameP)`

**Parameters**

- *refNum*  
Reference number of the net library.
- *configIndex*  
Index of the configuration to be renamed.
- *newNameP*  
Pointer to the new name. See [NetConfigNameType](#). The new name must not start with a period (.) or an underscore (\_).

**Returns** Returns one of the following values:

0  
Success.

`netErrConfigBadName`  
The new name begins with a period.

`netErrConfigCantDelete`  
The configuration at the specified index is a built-in alias or private configuration that cannot be renamed.

`netErrOutOfCmdBlocks`

`netErrParamErr`  
The specified index is out of range or there is no configuration at the index.

**Sockets  
Equivalent** None

**Comments** You cannot specify a name beginning with a period (.) or an underscore (\_). Names beginning with a period are reserved for the

built-in configuration aliases. Names beginning with an underscore are hidden configurations used internally by net library.

**Compatibility**    Implemented only if [3.2 New Feature Set](#) is present.

## NetLibConfigSaveAs Function

**Purpose**    Save the current net library settings as a configuration with the specified name.

**Prototype**    `Err NetLibConfigSaveAs (UInt16 refNum,  
                                  NetConfigNamePtr nameP)`

**Parameters**    `→ refNum`  
                    Reference number of the net library.  
  
                    `→ nameP`  
                    Pointer to a name for the configuration. See [NetConfigNameType](#). The name must not start with a period (.) or an underscore (\_).

**Returns**    Returns one of the following values:

0  
    Success.

`netErrConfigBadName`  
    The specified name begins with a period or underscore.

`netErrConfigTooMany`  
    Not enough space to add another configuration. The Net Library can hold up to 16 configuration.

`netErrOutOfCmdBlocks`

**Sockets  
Equivalent**    None

**Comments**    If the name you specify already exists, its configuration is replaced with this configuration.

You cannot specify a name beginning with a period (.) or an underscore (\_). Names beginning with a period are reserved for the built-in configuration aliases. Names beginning with an underscore are hidden configurations used internally by net library.

The net library assigns an index to this new configuration. The configuration's index remains constant, while its name may change.

## Net Library

### *NetLibConnectionRefresh*

---

Use [NetLibConfigIndexFromName\(\)](#) to obtain the configuration's index.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibConfigDelete\(\)](#), [NetLibConfigRename\(\)](#)

## NetLibConnectionRefresh Function

**Purpose** This routine is a convenience call for applications. It checks the status of all connections and optionally tries to open any that were closed.

**Declared In** `NetMgr.h`

**Prototype** `Err NetLibConnectionRefresh (UInt16 refNum,  
Boolean refresh, UInt8 *allInterfacesUpP,  
UInt16 *netIFErrP)`

**Parameters**

- $\rightarrow$  *refnum*  
Reference number of the net library.
- $\rightarrow$  *refresh*  
If true, any connections that aren't currently open are opened.
- $\leftarrow$  *allInterfacesUpP*  
Set to true if all connections are open.
- $\leftarrow$  *netIFErrP*  
First error encountered when reopening connections that were closed. (See [NetLibIFUp\(\)](#) for a list of possible values.)

**Returns** Returns one of the following values:

0  
Success.  
`netErrBufTooSmall`  
`netErrOutOfCmdBlocks`  
`netErrNoInterfaces`

**Sockets  
Equivalent** None.

**Comments** This function determines whether a connection is up based on the internal status of the TCP/IP stack. To test the presence of a “physical connection” (phone line, modem, serial cable), a command should be sent once it’s been determined that the logical connection is up. If the physical connection is broken, nothing returns and a timeout error eventually occurs.

## NetLibDmReceive Function

**Purpose** Receive data from a socket directly into a database record.

**Declared In** `NetMgr.h`

**Prototype**

```
Int16 NetLibDmReceive (UInt16 libRefNum,  
    NetSocketRef socket, void *recordP,  
    UInt32 recordOffset, UInt16 rcvLen,  
    UInt16 flags,  
    void *fromAddrP, UInt16 *fromLenP,  
    Int32 timeout,  
    Err *errP)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *socket*  
Descriptor for the open socket.
- ← *recordP*  
Pointer to beginning of record to receive data into. Must be locked for use.
- *recordOffset*  
Offset from beginning of record to read data into.
- *rcvLen*  
Maximum number of bytes to read.
- *flags*  
One or more `netIOFlagxxx` flags. See “[I/O Flags](#).”
- ← *fromAddrP*  
Pointer to buffer to hold address of sender (a [NetSocketAddrType](#) struct). Pass NULL if you don’t need sender information.

↔ *fromLenP*

On entry, size of *fromAddrP* buffer. On exit, actual size of returned address in *fromAddrP*. Pass NULL if you don't need sender information.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *errP*

Contains an error code if the return value is -1.

**Returns** Returns the number of bytes successfully received. If the return value is 0, the socket has been shut down by the remote host. If the return value is -1, an error has occurred and *errP* contains one of the following values:

0

No error.

*netErrTimeout*

Call timed out.

*netErrNotOpen*

The referenced net library has not been opened yet.

*netErrParamErr*

*netErrSocketNotOpen*

*netErrWouldBlock*

*netErrUserCancel*

*netErrOutOfMemory*

**Comments** This call behaves similarly to [NetLibReceive\(\)](#) but reads the data directly into a database record, which is normally write-protected. The caller must pass a pointer to the start of the record and an offset into the record of where to start the read.

## NetLibFinishCloseWait Function

|                           |                                                                                                                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>            | Forces the net library to do a complete close if it's currently in the close-wait state.                                                                                                                   |
| <b>Declared In</b>        | NetMgr.h                                                                                                                                                                                                   |
| <b>Prototype</b>          | Err NetLibFinishCloseWait (UInt16 libRefnum)                                                                                                                                                               |
| <b>Parameters</b>         | → <i>libRefnum</i><br>Reference number of the net library.                                                                                                                                                 |
| <b>Returns</b>            | Returns one of the following values:<br>0<br>Success.<br>netErrTimeout                                                                                                                                     |
| <b>Sockets Equivalent</b> | None.                                                                                                                                                                                                      |
| <b>Comments</b>           | This call checks the current open state of the net library. If it's in the close-wait state (see <a href="#">NetLibClose()</a> ), it forces the library to perform an immediate, complete close operation. |

## NetLibGetHostByAddr Function

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Looks up a host name given its IP address.                                                                                                                                                                                               |
| <b>Declared In</b> | NetMgr.h                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | NetHostInfoPtr NetLibGetHostByAddr<br>(UInt16 libRefNum, UInt8 *addrP, UInt16 len,<br>UInt16 type, NetHostInfoBufPtr bufP,<br>Int32 timeout, Err *errP)                                                                                  |
| <b>Parameters</b>  | → <i>libRefNum</i><br>Reference number of the net library.<br>→ <i>addrP</i><br>IP address of host to lookup.<br>→ <i>len</i><br>Length, in bytes, of *addrP.<br>→ <i>type</i><br>Type of addrP. See <a href="#">NetSocketAddrEnum</a> . |

## Net Library

### *NetLibGetHostByAddr*

---

← *bufP*

Pointer to a [NetHostInfoBufType](#) struct in which to store the results of the lookup.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *errP*

Contains an error code if the return value is 0.

**Returns** Returns a pointer to the [NetHostInfoType](#) portion of *bufP* that contains results of the lookup. If the return value is 0, an error has occurred, and *errP* contains one of the following values:

0

No error

`netErrTimeout`

Call timed out.

`netErrNotOpen`

The referenced net library has not been opened yet.

`netErrDNSNameTooLong`

`netErrDNSBadName`

`netErrDNSLabelTooLong`

`netErrDNSAllocationFailure`

`netErrDNSTimeout`

`netErrDNSUnreachable`

`netErrDNSFormat`

`netErrDNSServerFailure`

`netErrDNSNonexistentName`

`netErrDNSNIY`

`netErrDNSRefused`

`netErrDNSImpossible`

`netErrDNSNoRRS`

`netErrDNSAborted`

`netErrDNSBadProtocol`

```
netErrDNSTruncated
netErrDNSNoRecursion
netErrDNSIrrelevant
netErrDNSNotInLocalCache
netErrDNSNoPort
```

**Sockets Equivalent** `struct hostent *gethostbyaddr (char *addr, int len, int type);`

**Comments** This call queries the domain name server(s) to look up a host name given its IP address.

**See Also** [NetLibGetHostByName\(\)](#)

## NetLibGetHostByName Function

**Purpose** Looks up a host IP address given a host name.

**Declared In** `NetMgr.h`

**Prototype** `NetHostInfoPtr NetLibGetHostByName (UInt16 libRefNum, const Char *nameP, NetHostInfoBufPtr bufP, Int32 timeout, Err *errP)`

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *nameP*  
Name of host to look up.
- ← *bufP*  
Pointer to a [NetHostInfoBufType](#) struct in which to store the results of the lookup.
- *timeout*  
Maximum timeout in system ticks; -1 means wait forever.
- ← *errP*  
Contains an error code if the return value is 0.

**Returns** Returns a pointer to the [NetHostInfoType](#) portion of *bufP*, which contains results of the lookup. If the return value is 0, an error has occurred and *errP* contains one of the following values:

## Net Library

### *NetLibGetHostByName*

---

0  
No error

netErrTimeout  
Call timed out.

netErrNotOpen  
The referenced net library has not been opened yet.

netErrDNSNameTooLong

netErrDNSBadName

netErrDNSLabelTooLong

netErrDNSAllocationFailure

netErrDNSTimeout

netErrDNSUnreachable

netErrDNSFormat

netErrDNSServerFailure

netErrDNSNonexistantName

netErrDNSNIY

netErrDNSRefused

netErrDNSImpossible

netErrDNSNoRRS

netErrDNSAborted

netErrDNSBadProtocol

netErrDNSTruncated

netErrDNSNoRecursion

netErrDNSIrrelevant

netErrDNSNotInLocalCache

netErrDNSNoPort

#### **Sockets Equivalent**

struct hostent \*gethostbyname (char \*name);

**Comments** → *This call first checks the local name IP address host table in the net library preferences. If the entry is not found, it then queries the domain name server(s).*

**See Also** [NetLibGetHostByAddr\(\)](#),  
[NetLibGetMailExchangeByName\(\)](#)

## NetLibGetMailExchangeByName Function

**Purpose** Looks up the name of a host to use for a given mail exchange.

**Declared In** NetMgr.h

**Prototype**

```
Int16 NetLibGetMailExchangeByName
    (UInt16 libRefNum, Char *mailNameP,
     UInt16 maxEntries, Char hostNames[][255+1],
     UInt16 priorities[], Int32 timeout, Err *errP)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *mailNameP*  
Name of the mail exchange to look up.
- *maxEntries*  
Maximum number of host names to return.
- ← *hostNames*  
Array of character strings of length 255+1. The host name results are stored in this array. This array must be able to hold at least *maxEntries* host names.
- ← *priorities*  
Array of Words. The priorities of each host name found are stored in this array. This array must be at least *maxEntries* in length.
- *timeout*  
Maximum timeout in system ticks; -1 means wait forever.
- ← *errP*  
Contains an error code if the return value is less than 0.

**Returns** Returns the number of entries successfully found. If the return value is a negative number, an error has occurred, and *errP* contains one of the following values:

## Net Library

### *NetLibGetMailExchangeByName*

---

0  
No error  
netErrTimeout  
Call timed out.  
netErrNotOpen  
The referenced net library has not been opened yet.  
netErrDNSNameTooLong  
netErrDNSBadName  
netErrDNSLabelTooLong  
netErrDNSAllocationFailure  
netErrDNSTimeout  
netErrDNSUnreachable  
netErrDNSFormat  
netErrDNSServerFailure  
netErrDNSNonexistantName  
netErrDNSNIY  
netErrDNSRefused  
netErrDNSImpossible  
netErrDNSNoRRS  
netErrDNSAborted  
netErrDNSBadProtocol  
netErrDNSTruncated  
netErrDNSNoRecursion  
netErrDNSIrrelevant  
netErrDNSNotInLocalCache  
netErrDNSNoPort

**Sockets  
Equivalent**

None

- Comments** This call looks up the name(s) of host(s) to use for sending an e-mail. The caller passes the name of the mail exchange in `mailNameP` and gets back a list of host names to which the mail message can be sent.
- See Also** [NetLibGetHostByAddr\(\)](#), [NetLibGetHostByName\(\)](#)

## NetLibGetServByName Function

- Purpose** Looks up the port number for a standard TCP/IP service, given the desired protocol.
- Declared In** `NetMgr.h`
- Prototype**
- ```
NetServInfoPtr NetLibGetServByName
    (UInt16 libRefNum, const Char *servNameP,
     const Char *protoNameP,
     NetServInfoBufPtr bufP,
     Int32 timeout, Err *errP)
```
- Parameters**
- *libRefNum*  
Reference number of the net library.
  - *servNameP*  
Name of the service to look up. Possible services are "echo", "discard", "daytime", "qotd", "chargen", "ftp-data", "ftp", "telnet", "smtp", "time", "name", "finger", "pop2", "pop3", "nntp", "imap2".
  - *protoNameP*  
Desired protocol to use, either "udp" or "tcp".
  - ← *bufP*  
Pointer to a [NetServInfoBufType](#) struct in which to store the results of the lookup.
  - *timeout*  
Maximum timeout in system ticks; -1 means wait forever.
  - ← *errP*  
Contains an error code if the return value is 0.
- Returns** Returns a pointer to the [NetServInfoType](#) portion of *bufP* that contains results of the lookup. If the return value is 0, and error has occurred and *errP* contains one of the following values:
- 0  
No error

`netErrTimeout`

Call timed out.

`netErrNotOpen`

The referenced net library has not been opened yet.

`netErrUnknownProtocol`

`netErrUnknownService`

**Sockets  
Equivalent**

`struct servent *getservbyname (char *addr,  
char *proto);`

**Comments**

This call is a convenience call for looking up a standard port number given the name of a service and the protocol to use.

**See Also**

[NetLibGetHostByName\(\)](#)

## NetLibIFAttach Function

**Purpose**

Attach a new network interface.

**Declared In**

`NetMgr.h`

**Prototype**

`Err NetLibIFAttach (UInt16 libRefNum,  
UInt32 ifCreator, UInt16 ifInstance,  
Int32 timeout)`

**Parameters**

→ *libRefNum*

Reference number of the net library.

→ *ifCreator*

Creator of interface to attach.

→ *ifInstance*

Instance number of interface to attach. The instance number is one of the values returned by [NetLibIFGet\(\)](#).

→ *timeout*

Timeout in ticks; -1 means infinite timeout.

**Returns**

Returns one of the following values:

0

Success.

`netErrInterfaceNotFound`

`netErrTooManyInterfaces`

**Sockets Equivalent** None

**Comments** This call can be used to attach a new network interface to the net library. Network interfaces are self-contained databases of type 'neti'. The `ifCreator` parameter to this function is used to locate the network interface database of the given creator.

If the net library is already open when this call is made, the network interface's database will be located and then called to initialize itself and attach itself to the protocol stack in real time. If the net library is not open when this call is made, the creator and instance number of the interface are stored in the active configuration. You need to save the active configuration using [NetLibConfigSaveAs\(\)](#) if you want the interface to be initialized and attached to the stack the next time the net library is opened.

**See Also** [NetLibIFGet\(\)](#), [NetLibIFDetach\(\)](#)

## NetLibIFDetach Function

**Purpose** Detach a network interface from the protocol stack.

**Declared In** `NetMgr.h`

**Prototype**

```
Err NetLibIFDetach (UInt16 libRefNum,
                    UInt32 ifCreator, UInt16 ifInstance,
                    Int32 timeout)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *ifCreator*  
Creator of interface to detach.
- *ifInstance*  
Instance number of interface to detach.
- *timeout*  
Timeout in ticks; -1 means infinite timeout.

**Returns** Returns one of the following values:

- 0  
Success.
- `netErrInterfaceNotFound`

## Net Library

### *NetLibIFDown*

---

**Sockets  
Equivalent**

None

**Comments**

If the net library is already open when this call is made, the interface is brought down and detached from the protocol stack in real time. If the net library is not open when this call is made, the creator and instance number of the interface are removed from the active configuration. You need to save the active configuration using [NetLibConfigSaveAs\(\)](#) if you don't want the interface to be attached the next time the library is opened.

**See Also**

[NetLibIFGet\(\)](#), [NetLibIFAttach\(\)](#)

## NetLibIFDown Function

**Purpose**

Bring an interface down and hang up a connection.

**Declared In**

NetMgr.h

**Prototype**

```
Err NetLibIFDown (UInt16 libRefNum,  
                  UInt32 ifCreator, UInt16 ifInstance,  
                  Int32 timeout)
```

**Parameters**

→ *libRefNum*  
Reference number of the net library.

→ *ifCreator*  
Creator of interface to attach.

→ *ifInstance*  
Instance number of interface to attach.

→ *timeout*  
Timeout in ticks; -1 means wait forever.

**Returns**

Returns one of the following values:

0  
Success.

netErrNotOpen  
The referenced net library has not been opened yet.

netErrInterfaceNotFound

**Sockets  
Equivalent**

None

- Comments** The net library must be open before this call can be made. For dial-up interfaces, this call terminates a connection and hangs up the modem if necessary.
- [NetLibClose\(\)](#) automatically brings down any attached interfaces, so this routine doesn't normally have to be called.
- If the interface is already down, this routine returns immediately with no error.
- See Also** [NetLibIFGet\(\)](#), [NetLibIFAttach\(\)](#), [NetLibIFDetach\(\)](#), [NetLibIFUp\(\)](#)

## NetLibIFGet Function

- Purpose** Get the creator and instance number of an installed interface by index.
- Declared In** NetMgr.h
- Prototype**

```
Err NetLibIFGet (UInt16 libRefNum, UInt16 index,
                 UInt32 *ifCreatorP, UInt16 *ifInstanceP)
```
- Parameters**
- *libRefNum*  
Reference number of the net library.
  - *index*  
Index of the interface to get. Indices start at 0.
  - ← *ifCreatorP*  
The interface's creator.
  - ← *ifInstanceP*  
The interface's instance number.
- Returns** Returns one of the following values:
- 0  
Success.
  - netErrInvalidInterface  
Index too high
  - netErrPrefNotFound  
No current value for setting.
- Sockets Equivalent** None

- Comments** To get a list of all installed interfaces, call this function with successively increasing indices starting from 0 until the error `netErrInvalidInterface` is returned.
- The `ifCreator` and `ifInstance` values returned from this call can then be used with the [NetLibSettingGet\(\)](#) call to get more information about that particular interface.
- See Also** [NetLibIFAttach\(\)](#), [NetLibIFDetach\(\)](#), “[Settings for Interface Selection](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*

## NetLibIFSettingGet Function

- Purpose** Retrieves a network interface specific setting.
- Declared In** `NetMgr.h`
- Prototype**

```
Err NetLibIFSettingGet (UInt16 libRefNum,
                        UInt32 ifCreator, UInt16 ifInstance,
                        UInt16 setting, void *valueP,
                        UInt16 *valueLenP)
```
- Parameters**
- *libRefNum*  
Reference number of the net library.
  - *ifCreator*  
Creator of the network interface.
  - *ifInstance*  
Instance number of the network interface.
  - *setting*  
Setting to retrieve; one of the `NetIFSettingEnum` constants.
  - ← *valueP*  
Space for return value of setting.
  - ↔ *valueLenP*  
On entry, size of *valueP*. On exit, actual size of setting.
- Returns** Returns one of the following values:
- 0  
Success.

`netErrUnknownSetting`  
 Invalid setting constant.

`netErrPrefNotFound`  
 No current value for setting.

`netErrBufTooSmall`  
`valueP` was too small to hold entire setting. Setting value was truncated to fit in `valueP`.

`netErrUnimplemented`

`netErrInterfaceNotFound`

`netErrBufWrongSize`

**Sockets  
 Equivalent**

None

**Comments**

This call can be used to retrieve the current value of any network interface setting. The caller must pass a pointer to a buffer to hold the return value (`valueP`), the size of the buffer (`*valueLenP`), and the setting ID (`setting`). The setting ID is one of the constants in the `NetIFSettingEnum` type.

Some settings, such as the login script, are variable size. For these types of settings, you can obtain the actual size required for the buffer by passing 0 for `*valueLenP`. The required size is returned in `valueLenP`.

[Table 61.2](#) lists the network interface settings and the size of each setting. Some are only applicable to certain types of interfaces. Settings not applicable to a specific interface can be safely ignored and not set to any particular value.

**Table 61.2 Network Interface Settings**

<b>netIFSetting...</b>	<b>Type</b>	<b>Description</b>
ResetAll	void	Use with <a href="#">NetLibIFSettingSet()</a> only. This clears all other settings for the interface to their default values.
Up	UInt8	Read-only. true if interface is currently up.
Name	Char[32]	Read-only. Name of this interface.
ReqIPAddr	UInt32	IP address of interface.
SubnetMask	UInt32	Subnet mask for interface. Doesn't need to be specified for PPP or SLIP type connections.
Broadcast	UInt32	Broadcast address for interface. Doesn't need to be specified for PPP or SLIP type connections.
Username	Char[32]	User name. Only required if the login script uses the user name substitution escape sequence in it. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting.
Password	Char[32]	Password. Only required if the login script uses the password substitution escape sequence in it. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting. If the login script uses password substitution and no password setting is set, the user will be prompted for a password at connect time.
AuthUsername	Char[32]	Authentication user name. Only required if the authentication protocol uses a different user name than the what's in the netIFSettingUsername setting. If this setting is empty (valueLen of 0), the Username setting will be used instead. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting.

**Table 61.2 Network Interface Settings (*continued*)**

<b>netIFSetting...</b>	<b>Type</b>	<b>Description</b>
AuthPassword	Char [32]	Authentication password. If "\$" then the user will be prompted for the authentication password at connect time. Else, if 0 length, then the netIFSettingPassword setting or the result of its prompt will be used instead. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting.
ServiceName	Char []	Service name. Used for display purposes while showing the connection progress dialog box. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting.
LoginScript	Char []	Login script. Only required if the particular service requires a login sequence. Call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0 to remove this setting. See below for a description of the login script format.
ConnectLog	Char []	Connect log. Generally, this setting is just retrieved, not set. It contains a log of events from the most recent login. To clear this setting, call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0.
InactivityTimeout	UInt16	Maximum number of seconds of inactivity allowed. Set to 0 to ignore.
EstablishmentTime out	UInt16	Maximum delay, in seconds, allowed between each stage of connection establishment or login script line. Must be non-zero.
DynamicIP	UInt8	If non-zero, negotiate for an IP address. If zero, the IP address specified in the netIFSettingReqIPAddr setting will be used. Default is false.
VJCompEnable	UInt8	If non-zero, enable VJ header compression. Default is true for PPP, false for SLIP, and true for CSLIP.

**Table 61.2 Network Interface Settings (*continued*)**

<b>netIFSetting...</b>	<b>Type</b>	<b>Description</b>
VJCompSlots	UInt8	Number of slots to use for VJ compression. Default is 4 for PPP and 16 for SLIP and CSLIP. More slots require more memory so it is best to keep this number to a minimum.
MTU	UInt16	Maximum transmission unit in octets. Currently not implemented in SLIP or PPP.
AsyncCtlMap	UInt32	Bit mask of characters to escape for PPP. Default is 0.
PortNum	UInt16	Which serial communication port to use. Port 0 is the only port available on the device.
BaudRate	UInt32	Serial port baud rate to use in bits per second.
FlowControl	UInt8	If bit 0 is 1, use hardware handshaking on the serial port. Default is no hardware handshaking.
StopBits	UInt8	Number of stop bits. Default is 1.
ParityOn	UInt8	true if parity detection enabled. Default is false.
ParityEven	UInt8	true for even parity detection. Default is true.
UseModem	UInt8	If true, dial-up through modem. If false, go direct over serial port
PulseDial	UInt8	If true, pulse dial modem. Else, tone dial. Default is tone dial.
ModemInit	Char []	Zero-terminated modem initialization string, not including the "AT". If not specified (valueLen of 0), the modem initialization string from system preferences are used.
ModemPhone	Char []	Zero-terminated modem phone number string. Only required if netIFSettingUseModem is true.

**Table 61.2 Network Interface Settings (*continued*)**

<b>netIFSetting...</b>	<b>Type</b>	<b>Description</b>
RedialCount	UInt16	Number of times to re-dial modem when trying to establish a connection. Only required if netIFSettingUseModem is true.
DNSQuery	UInt8	true if PPP queries for DNS address. The default is true.
TraceBits	UInt32	A bitfield of various trace bits. See “ <a href="#">Tracing Bits</a> .”  An application can get a list of events in the trace buffer using the <a href="#">NetLibMaster()</a> call. Each interface has its own trace bits setting so that trace event recording in each interface can be selectively enabled or disabled.
ActualIPAddr	UInt32	Read-only. The actual IP address that the interface ends up using. The login script execution engine stores the result of the “g” (get IP address) command here as does the PPP negotiation logic.
ServerIPAddr	UInt32	Read-only. The IP address of the PPP server we’re connected to.
BringDownOnPowerDown	UInt8	true if the interface is brought down when the Palm OS device is turned off.
RawMode	UInt32	Specifies if the interface is in raw mode. The net library places an interface in raw mode when it is bound to a raw socket in the raw domain. Raw sockets are available in Palm OS version 3.0 and higher.
DriverVersion	Char[20]	Read-only. The version number of the network interface device driver. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
FirmwareVersion	Char[20]	Read-only. The firmware version of the network interface device, if any. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.

**Table 61.2 Network Interface Settings (*continued*)**

netIFSetting...	Type	Description
FirmwareDate	UInt32	Read-only. Firmware date in seconds since midnight, January 1, 1904. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211Device	UInt8	Read-only. Indicates whether or not the interface supports IEEE 802.11 wireless networking. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211ESSID	Char[32]	For IEEE 802.11 interfaces only. The ESS ID of the radio. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211AccessPointBSSID	UInt8[6]	Read-only. For IEEE 802.11 interfaces only. The BSS ID (MAC address) of the access point to which the radio is connected. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211AssociationStatus	UInt8	Read-only. For IEEE 802.11 interfaces only. true if the radio is associated. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211MKKCallSign	Char[15]	Read-only. For IEEE 802.11 interfaces with radios programmed for operation in Japan only. The MKK call sign. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.
80211CountryText	Char[34]	Read-only. For IEEE 802.11 interfaces only. The radio's country code, which the radio uses to check if it operates within a particular country's regulations. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.

**See Also** [NetLibIFSettingSet\(\)](#), [NetLibSettingGet\(\)](#), [NetLibSettingSet\(\)](#), “[Interface Specific Settings](#)” in the *Palm OS Programmer's Companion*, vol. II, *Communications*

## NetLibIFSettingSet Function

<b>Purpose</b>	Sets a network interface specific setting.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Err NetLibIFSettingSet (UInt16 libRefNum,                         UInt32 ifCreator, UInt16 ifInstance,                         UInt16 setting, void *valueP, UInt16 valueLen)</pre>
<b>Parameters</b>	<ul style="list-style-type: none"><li>→ <i>libRefNum</i> Reference number of the net library.</li><li>→ <i>ifCreator</i> Creator of the network interface.</li><li>→ <i>ifInstance</i> Instance number of the network interface.</li><li>→ <i>setting</i> The setting to set, one of the NetIFSettingEnum constants. See <a href="#">Table 61.2</a>.</li><li>→ <i>valueP</i> Space new value of setting.</li><li>→ <i>valueLen</i> Size of new setting.</li></ul>
<b>Returns</b>	Returns one of the following values: <ul style="list-style-type: none"><li>0 Success.</li><li>netErrUnknownSetting Invalid setting constant.</li><li>netErrPrefNotFound No current value for setting.</li><li>netErrUnimplemented</li><li>netErrInterfaceNotFound</li><li>netErrBufWrongSize</li><li>netErrReadOnlySetting</li></ul>
<b>Sockets Equivalent</b>	None

**Comments** This call can be used to set the current value of any network interface setting. The caller must pass a pointer to a buffer which holds the new value (`valueP`), the size of the buffer (`valueLen`), and the setting ID (`setting`).

See [NetLibIFSettingGet\(\)](#) for an explanation of each of the settings.

Of particular interest is the `netIFSettingResetAll` setting, which, if used, resets all settings for the interface to their default values. When using this setting, `valueP` and `valueLen` are ignored.

**See Also** [NetLibIFSettingGet\(\)](#), [NetLibSettingGet\(\)](#), [NetLibSettingSet\(\)](#), “[Interface Specific Settings](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*

## NetLibIFUp Function

**Purpose** Bring an interface up and establish a connection.

**Declared In** `NetMgr.h`

**Prototype**

```
Err NetLibIFUp (UInt16 libRefNum,
                UInt32 ifCreator, UInt16 ifInstance)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *ifCreator*  
Creator of interface to attach.
- *ifInstance*  
Instance number of interface to attach.

**Returns** Returns one of the following values:

- 0  
Success.
- `netErrNotOpen`  
The referenced net library has not been opened yet.
- `netErrInterfaceNotFound`
- `netErrUserCancel`
- `netErrBadScript`

	<code>netErrPPPTimeout</code>
	<code>netErrAuthFailure</code>
	<code>netErrPPPAddressRefused</code>
<b>Sockets Equivalent</b>	None
<b>Comments</b>	<p>The net library must be open before this call can be made. For dial-up interfaces, this call will dial up the modem if necessary and run through the connect script to establish the connection.</p> <p>If the interface is already up, this routine returns immediately with no error. This call doesn't take a timeout parameter because it relies on each interface to have its own established timeout setting.</p>
<b>See Also</b>	<a href="#">NetLibIFGet()</a> , <a href="#">NetLibIFAttach()</a> , <a href="#">NetLibIFDetach()</a> , <a href="#">NetLibIFDown()</a>

## NetLibMaster Function

<b>Purpose</b>	Retrieves the network statistics, interface statistics, and the contents of the trace buffer.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<code>Err NetLibMaster (UInt16 libRefNum, UInt16 cmd, NetMasterPBPtr pbP, Int32 timeout)</code>
<b>Parameters</b>	<p>→ <i>libRefNum</i>  Reference number of the net library.</p> <p>→ <i>cmd</i>  Function to perform (NetMasterEnum type). The following commands are supported:</p> <p><a href="#">netMasterInterfaceInfo</a></p> <p><a href="#">netMasterInterfaceStats</a></p> <p><a href="#">netMasterIPStats</a></p> <p><a href="#">netMasterICMPStats</a></p> <p><a href="#">netMasterUDPStats</a></p> <p><a href="#">netMasterTCPStats</a></p> <p><a href="#">netMasterTraceEventGet</a></p>

	↔ <i>pbP</i>	Command parameter block.
	→ <i>timeout</i>	Timeout in ticks; -1 means wait forever.
<b>Returns</b>	Returns one of the following values:	
	0	No error
	<code>netErrNotOpen</code>	The referenced net library has not been opened yet.
	<code>netErrParamErr</code>	
	<code>netErrUnimplemented</code>	
<b>Sockets Equivalent</b>	None	
<b>Comments</b>	<p>This call allows applications to get detailed information about the net library. This information is usually helpful in debugging network configuration problems.</p> <p>This function takes a command word (<i>cmd</i>) and parameter block pointer (<i>pbP</i>) as arguments and returns its results in the parameter block on exit. Which values you must specify in the parameter block and which values are returned are specific to the command you specify.</p>	
	<b>netMasterInterfaceInfo</b>	
	The <code>pbP-&gt;interfaceInfo</code> struct specifies interface information.	
	→ <i>index</i>	Index of interface to fetch info about.
	← <i>creator</i>	Creator of interface.
	← <i>instance</i>	Instance of interface.
	← <i>netIFP</i>	Private interface info pointer.
	← <i>drvName</i>	Driver type that interface uses ("PPP", "SLIP", etc.).
	← <i>hwName</i>	Hardware driver name ("Serial Library", etc.).

←	<code>localNetHdrLen</code>	Number of bytes in local net header.
←	<code>localNetTrailerLen</code>	Number of bytes in local net trailer.
←	<code>localNetMaxFrame</code>	Local net maximum frame size.
←	<code>ifName</code>	Interface name with instance number concatenated.
←	<code>driverUp</code>	true if interface driver is up.
←	<code>ifUp</code>	true if interface media layer is up.
←	<code>hwAddrLen</code>	Length of interface's hardware address.
←	<code>hwAddr</code>	Interface's hardware address.
←	<code>mtu</code>	Maximum transfer unit of interface.
←	<code>speed</code>	Speed in bits per second.
←	<code>lastStateChange</code>	Time in milliseconds of last state change.
←	<code>ipAddr</code>	IP address of interface.
←	<code>subnetMask</code>	Subnet mask of local network.
←	<code>broadcast</code>	Broadcast address of local network.

### **netMasterInterfaceStats**

The `pbP->interfaceStats` structure specifies interface statistics.

→	<code>index</code>	Index of interface to fetch info about.
←	<code>inOctets</code>	Number of octets received.
←	<code>inUcastPkts</code>	Number of packets received.
←	<code>inNUcastPkts</code>	Number of broadcast packets received.

←	<code>inDiscards</code>	Number of incoming packets that were discarded.
←	<code>inErrors</code>	Number of packet errors encountered.
←	<code>inUnknownProtos</code>	Number of unknown protocols encountered.
←	<code>outOctets</code>	Number octets sent.
←	<code>outUcastPkts</code>	Number of packets sent.
←	<code>outNUcastPkts</code>	Number of broadcast packets sent.
←	<code>outDiscards</code>	Number of packets discarded.
←	<code>outErrors</code>	Number of outbound packet errors.

#### **netMasterIPStats**

The `pbP->ipStats` structure contains statistics about the IP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterICMPStats**

The `pbP->icmpStats` structure contains statistics about the ICMP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterUDPStats**

The `pbP->udpStats` structure contains statistics about the UDP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterTCPStats**

The `pbP->tcpStats` structure contains statistics about the TCP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterTraceEventGet**

The `pbP->traceEventGet` structure contains a trace event.

→ `index` Index of event to fetch.

← `textP` Pointer to text string to return event in. Should be at least 256 bytes long.

**See Also** [NetLibSettingSet\(\)](#)

## NetLibOpen Function

**Purpose** Opens and initializes the net library.

**Declared In** `NetMgr.h`

**Prototype** `Err NetLibOpen (UInt16 libRefnum,  
 UInt16 *netIFErrsP)`

**Parameters** → `libRefnum`

Reference number of the net library.

← `netIFErrsP`

First error encountered when bringing up network interfaces.  
 (See [NetLibIFUp\(\)](#) for a list of possible values.)

**Returns** Returns one of the following values:

0

No error.

`netErrAlreadyOpen`

Not really an error; returned if library was already open and the open count was simply incremented.

`netErrOutOfMemory`

Not enough memory available to open the library.

`netErrNoInterfaces`

Incorrect setup.

`netErrPrefNotFound`

Incorrect setup.

**Comments** Applications must call this function before using the net library. If the net library was already open, `NetLibOpen` increments its open count. Otherwise, it opens the library, initializes it, starts up the net protocol stack component of the library as a separate task, and brings up all attached network interfaces.

NetLibOpen uses settings saved in the net library's preferences database during initialization. These settings include the interfaces to attach, the IP addresses, etc. It's assumed that these settings have been previously set up by a preference panel or equivalent so an application doesn't normally have to set them up before calling NetLibOpen.

If any of the attached interfaces fails to come up, \*netIFErrsP will contain the error number of the first interface that encountered a problem.

**Compatibility** NetLibOpen behaves slightly differently in version 3.2 and later than it does in previous releases. In version 3.2 and later, NetLibOpen calls [NetLibOpenConfig\(\)](#) specifying the default configuration. NetLibOpenConfig reverts all settings to their saved, default values before opening the net library.

**See Also** [SysLibFind\(\)](#), [NetLibClose\(\)](#), [NetLibOpenCount\(\)](#)

## NetLibOpenConfig Function

**Purpose** Opens and initializes the net library with the specified configuration.

**Prototype**

```
Err NetLibOpenConfig (UInt16 refNum,  
    UInt16 configIndex, UInt32 openFlags,  
    UInt16 *netIFErrP)
```

**Parameters**

- *refNum*  
Reference number of the net library.
- *configIndex*  
Index of the configuration to use. 0 means use the default configuration as defined in the Network preferences panel.
- *openFlags*  
Not used. Pass 0 for this parameter.
- ← *netIFErrP*  
Pointer to return error code for interfaces.

**Returns** Returns one of the following values:

0  
No error.

`memErrNotEnoughSpace`

`netErrAlreadyOpen`

Not really an error; returned if library was already open and the open count was simply incremented.

`netErrAlreadyOpenWithAnotherConfig`

Another application has the net library open with a configuration that is incompatible with the one specified.

`netErrBufTooSmall`

`netErrConfigAliasErr`

A configuration alias was specified, but the alias could not be resolved.

`netErrConfigCantDelete`

`netErrConfigEmpty`

The configuration is not defined.

`netErrConfigNotFound`

The specified configuration index is invalid.

`netErrInterfaceNotFound`

`netErrOutOfCmdBlocks`

`netErrOutOfMemory`

Not enough memory available to open the library.

`netErrNoInterfaces`

Incorrect setup.

`netErrParamErr`

`netErrPrefNotFound`

Incorrect setup.

`netErrTimeout`

**Sockets  
Equivalent**

None

**Comments**

Use this routine instead of [NetLibOpen\(\)](#) when you want to open the net library with a non-default configuration. If the default net library configuration is not suitable for your application, you may use one of the built-in aliases to specify a configuration that is suitable (see "[Configuration Aliases](#)").

NetLibOpenConfig tries to open the net library and initialize it with the specified configuration. If another application has the net library open with an incompatible configuration, it returns an error. If the net library is in the close-wait state, this function completely closes the net library and then reopens it using the new configuration. If the net library can be opened with the new configuration, NetLibOpenConfig first saves the current configuration so that it can be restored when your application closes the net library.

Typically, applications use the [NetLibConfigList\(\)](#) function to obtain the list of available configurations and present this list to the user. Then they call [NetLibConfigIndexFromName\(\)](#) with the user's selection to get the index of the configuration that the user selected.

The constant netConfigIndexCurSettings specifies the current configuration. You can specify netConfigIndexCurSettings as the configIndex for testing purposes.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibOpen\(\)](#), [SysLibFind\(\)](#), [NetLibClose\(\)](#), [NetLibOpenCount\(\)](#)

## NetLibOpenCount Function

**Purpose** Retrieves the open count of the net library.

**Declared In** NetMgr.h

**Prototype** Err NetLibOpenCount (UInt16 refNum,  
                          UInt16 \*countP)

**Parameters**  $\rightarrow$  *refNum*  
Reference number of the net library.

$\leftarrow$  *countP*  
Contains the open count of the net library upon return.

**Returns** Always returns 0.

**Sockets Equivalent** None.

**Comments** This call will most likely only be used by the Network preferences panel. Most applications will simply call [NetLibOpen\(\)](#) unconditionally during startup and [NetLibClose\(\)](#) when they exit.

## NetLibReceive Function

**Purpose** Receive data from a socket into a single buffer.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibReceive (UInt16 libRefNum,  
                           NetSocketRef socket, void *bufP,  
                           UInt16 bufLen, UInt16 flags, void *fromAddrP,  
                           UInt16 *fromLenP, Int32 timeout, Err *errP)`

**Parameters**

- *libRefNum*  
     Reference number of the net library.
- *socket*  
     Descriptor for the open socket.
- ← *bufP*  
     Pointer to buffer to hold received data.
- *bufLen*  
     Length of *bufP* buffer.
- *flags*  
     One or more `netIOFlagxxx` flags. See “[I/O Flags](#).”
- ← *fromAddrP*  
     Pointer to buffer to hold address of sender (a [NetSocketAddrType](#)).
- ↔ *fromLenP*  
     On entry, size of *fromAddrP* buffer. On exit, actual size of returned address in *fromAddrP*.
- *timeout*  
     Maximum timeout in system ticks; -1 means wait forever.
- ← *errP*  
     Contains an error code if the return value is -1.

**Returns** Returns the number of bytes successfully received. If the return value is 0, the socket has been shut down by the remote host. If the

return value is -1, an error has occurred, and `errP` contains one of the following values:

0

No error.

`netErrTimeout`

Call timed out.

`netErrNotOpen`

The referenced net library has not been opened yet.

`netErrParamErr`

`netErrSocketNotOpen`

`netErrWouldBlock`

`netErrUserCancel`

**Sockets  
Equivalent**

```
int recvfrom (int socket, const void *bufP,  
int buflen, int flags, const void *fromAddrP,  
int *fromLenP);
```

```
int recv (int socket, const void *bufP,  
int buflen, int flags);
```

```
int read (int socket, const void *bufP,  
int buflen);
```

**Comments**

For stream-based sockets, this call reads whatever bytes are available and returns the number of bytes actually read into the caller's buffer. If there is no data available, this call will block until at least one byte arrives, until the socket is shut down by the remote host, or until a timeout occurs.

For datagram-based sockets, this call reads a complete datagram and returns the number of bytes in the datagram. If the caller's buffer is not large enough to hold the entire datagram, the end of the datagram is discarded. If a datagram is not available, this call will block until one arrives, or until the call times out.

The data is read into a single buffer pointed to by `bufP`.

[NetLibSend\(\)](#), [NetLibSendPB\(\)](#)

## NetLibReceivePB Function

<b>Purpose</b>	Receive data from a socket into a multi-buffer gather-read array.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<pre>Int16 NetLibReceivePB (UInt16 libRefNum,                       NetSocketRef socket, NetIOParamType *pbP,                       UInt16 flags, Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>socket</i> Descriptor for the open socket.</p> <p>→ <i>pbP</i> Pointer to parameter block containing buffer info.</p> <p>→ <i>flags</i> One or more <code>netIOFlagxxx</code> flags. See “<a href="#">I/O Flags</a>.”</p> <p>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</p> <p>← <i>errP</i> Contains an error code if the return value is -1.</p>
<b>Returns</b>	<p>Returns the number of bytes successfully received. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and <i>errP</i> contains one of the following values:</p> <p>0 No error.</p> <p><code>netErrTimeout</code> Call timed out.</p> <p><code>netErrNotOpen</code> The referenced net library has not been opened yet.</p> <p><code>netErrParamErr</code></p> <p><code>netErrSocketNotOpen</code></p> <p><code>netErrWouldBlock</code></p>
<b>Sockets Equivalent</b>	<pre>int recvmsg (int socket, const struct msghdr *pbP,             int flags);</pre>

**Comments** The pbP parameter is a pointer to a NetIOParamType structure. NetIOParamType is defined as follows:

**Prototype**

```
typedef struct {
    UInt8      *addrP;
    UInt16     addrLen;
    NetIOVecPtr iov;
    UInt16     iovLen;
    UInt8      *accessRights;
    UInt16     accessRightsLen;
} NetIOParamType, *NetIOParamPtr;
```

You provide the following information in this struct:

addrP	Address of sender, set by NetLibReceivePB. Set to 0 if you don't require this field.
addrLen	Length of *addrP.
iov	Array of buffers into which the data should be received. NetIOVecPtr is a pointer to a NetIOVecType structure, which has two fields: <div><div>bufP</div><div>Pointer to a buffer.</div><div>bufLen</div><div>Length of bufP.</div></div>
iovLen	Length of the iov array.
accessRights	Access rights. This field currently isn't used and should be set to 0.
accessRightsLen	Length of the *accessRights. This field currently isn't used and should be set to 0.

For stream-based sockets, this call reads whatever bytes are available and returns the number of bytes actually read into the caller's buffer. If no data is available, this call will block until at least one byte arrives, until the socket is shut down by the remote host, or until a timeout occurs.

For datagram-based sockets, this call reads a complete datagram and returns the number of bytes in the datagram. If the caller's buffer is not large enough to hold the entire datagram, the end of the datagram is discarded. If a datagram is not available, this call will block until one arrives, or until the call times out.

The data is read into the gather-read array specified by the `pbP->iov` array.

**See Also** [NetLibReceive\(\)](#), [NetLibDmReceive\(\)](#), [NetLibSend\(\)](#), [NetLibSendPB\(\)](#)

## NetLibSelect Function

**Purpose** Blocks until I/O is ready on one or more descriptors, where a descriptor can represent socket input, socket output, or a user input event like a pen tap or key press.

**Declared In** `NetMgr.h`

**Prototype**

```
Int16 NetLibSelect (UInt16 libRefNum,
                   UInt16 width, NetFDSetType *readFDs,
                   NetFDSetType *writeFDs,
                   NetFDSetType *exceptFDs,
                   Int32 timeout, Err *errP)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *width*  
Number of descriptor bits to check in the *readFDs*, *writeFDs*, and *exceptFDs* descriptor sets.
- ↔ *readFDs*  
Pointer to 32-bit `NetFDSetType` containing set of bits representing descriptors to check for input.
- ↔ *writeFDs*  
Pointer to 32-bit `NetFDSetType` containing set of bits representing descriptors to check for output.
- ↔ *exceptFDs*  
Pointer to 32-bit `NetFDSetType` containing set of bits representing descriptors to check for exception conditions. This parameter is ignored. Upon return, its bits are always cleared.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *errP*

Contains an error code if the return value is -1.

**Returns** Returns the sum total number of ready file descriptors in *\*readFDs*, *\*writeFDs*, and *\*exceptFDs*. Returns 0 upon timeout. If the return value is -1, an error has occurred, and *errP* contains one of the following values:

0

No error

*netErrTimeout*

Call timed out.

*netErrNotOpen*

The referenced net library has not been opened yet.

**Sockets  
Equivalent**

```
int select (int width, fd_set *readfds,  
fd_set *writefds, fd_set *exceptfds,  
struct timeval *timeout);
```

**Comments**

This call blocks until one or more descriptors are ready for I/O. In the Palm OS environment, a descriptor is either a *NetSocketRef* or the “stdin” descriptor, *sysFileDescStdIn*. The *sysFileDescStdIn* descriptor will be ready for input whenever a user event is available like a pen tap or key press.

The caller should set which bits in each descriptor set need to be checked by using the *netFDZero* and *netFDSet* macros. After this call returns, the macro *netFDIsSet* can be used to determine which descriptors in each set are actually ready.

On exit, the total number of ready descriptors is returned and each descriptor set is updated with the appropriate bits set for each ready descriptor in that set.

The following example illustrates how to use this call to check for input on a socket or a user event:

---

```
Err      err;  
NetSocketRef  socket;  
NetFDSetType  readFDs, writeFDs, exceptFDs;  
Int16        numFDs;  
UInt16        width;
```

```
// Create the descriptor sets
netFDZero(&readFDs);
netFDZero(&writeFDs);
netFDZero(&exceptFDs);
netFDSet(sysFileDescStdIn, &readFDs);
netFDSet(socket, &readFDs);

// Calculate the max descriptor number and
// use that +1 as the max width.
// Alternatively, we could simply use the
// constant netFDSetSize as the width which
// is simpler but makes the NetLibSelect call
// slightly slower.
width = sysFileDescStdIn;
if (socket > width) width = socket;

// Wait for any one of the descriptors to be
// ready.
numFDs = NetLibSelect(AppNetRefnum, width+1,
    &readFDs, &writeFDs, &exceptFDs,
    AppNetTimeout, &err);
```

---

Also see the NetSample example application in the Palm OS Examples folder. The function CmdTelnet in the file CmdTelnet.c shows how to use the Berkeley sockets select function and how to interpret the results.

**See Also** [NetLibSocketOptionSet\(\)](#)

## NetLibSend Function

<b>Purpose</b>	Send data to a socket from a single buffer.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Int16 NetLibSend (UInt16 libRefNum,     NetSocketRef socket, void *bufP,     UInt16 bufLen,     UInt16 flags, void *toAddrP, UInt16 toLen,     Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i></p> <p>Reference number of the net library.</p>

## Net Library

### *NetLibSend*

---

- *socket*  
Descriptor for the open socket.
- *bufP*  
Pointer to data to write.
- *bufLen*  
Length of data to write
- *flags*  
One or more `netIOFlagxxx` flags. See “[I/O Flags](#).”
- *toAddrP*  
Address to send to (a pointer to a [NetSocketAddrType](#)), or 0.
- *toLen*  
Size of *toAddrP* buffer.
- *timeout*  
Maximum timeout in system ticks; -1 means wait forever.
- ← *errP*  
Contains an error code if the return value is -1.

**Returns** Returns the number of bytes successfully sent. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and *errP* contains one of the following values:

- 0  
No error.
- `netErrTimeout`  
Call timed out.
- `netErrNotOpen`  
The referenced net library has not been opened yet.
- `netErrParamErr`
- `netErrSocketNotOpen`
- `netErrMessageTooBig`
- `netErrSocketNotConnected`
- `netErrSocketClosedByRemote`
- `netErrIPCantFragment`

```
netErrIPNoRoute
netErrIPNoSrc
netErrIPNoDst
netErrIPktOverflow
netErrOutOfCmdBlocks
netErrOutOfPackets
netErrInterfaceNotFound
netErrInterfaceDown
netErrUnreachableDest
netErrNoMultiPktAddr
netErrWouldBlock
```

**Sockets  
Equivalent**

```
int sendto (int socket, const void *bufP,
int bufLen, int flags, const void *toAddrP,
int toLen);

int send (int socket, const void *bufP,
int bufLen, int flags);

int write (int socket, const void *bufP,
int bufLen,);
```

**Comments**

This call attempts to write data to the specified socket and returns the number of bytes actually sent, which may be less than or equal to the requested number of bytes. The data is passed in a single buffer that `bufP` points to.

For datagram sockets, you must only send a single packet at a time. If the data is too large to fit in a single UDP packet (1536 bytes), no data is sent and -1 is returned.

The `toAddrP` field applies only to datagram sockets without an existing connection. An error is returned if the datagram socket was previously connected and `toAddrP` is specified. Stream-based sockets, by definition, must have a connection established with a remote host before data can be written. Raw sockets (supported in Palm OS version 3.0 and higher) must construct the entire IP header, including the destination address, before data can be sent; thus, the address is taken from the data to be sent.

If there isn't enough buffer space to send any data, this call will block until there is enough buffer space, or until a timeout.

---

**NOTE:** For stream-based sockets, this call may write only a portion of the desired data. It always returns the number of bytes actually written. Consequently, the caller should be prepared to call this routine repeatedly until the desired number of bytes have been written, or until it returns 0 or -1.

---

## NetLibSendPB Function

<b>Purpose</b>	Send data to a socket from a scatter-write array.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Int16 NetLibSendPB (UInt16 libRefNum,     NetSocketRef socket, NetIOParamType *pbP,     UInt16 flags, Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<ul style="list-style-type: none"><li>→ <i>libRefNum</i> Reference number of the net library.</li><li>→ <i>socket</i> Descriptor for the open socket.</li><li>→ <i>pbP</i> Pointer to parameter block containing buffer info. See the description in <a href="#">NetLibReceivePB()</a>.</li><li>→ <i>flags</i> One or more netIOFlagxxx flags. See "<a href="#">I/O Flags</a>."</li><li>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</li><li>← <i>errP</i> Contains an error code if the return value is -1.</li></ul>
<b>Returns</b>	Returns the number of bytes successfully sent. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and <i>errP</i> contains one of the following values:

0

No error.

netErrTimeout

Call timed out.

netErrNotOpen

The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrMessageTooBig

netErrSocketNotConnected

netErrSocketClosedByRemote

netErrIPCantFragment

netErrIPNoRoute

netErrIPNoSrc

netErrIPNoDst

netErrIPktOverflow

netErrOutOfCmdBlocks

netErrOutOfPackets

netErrInterfaceNotFound

netErrInterfaceDown

netErrUnreachableDest

netErrNoMultiPktAddr

netErrWouldBlock

**Sockets  
Equivalent**

int sendmsg (int socket, const struct msghdr \*pbP,  
int flags);

**Comments**

This call attempts to write data to the given socket and returns the number of bytes actually sent, which may be less than or equal to the requested number of bytes. The data is passed in the scatter-write array specified in the pbP parameter block.

For datagram sockets, you must only send a single packet at a time. If the data is too large to fit in a single UDP packet, no data is sent and -1 is returned.

The `toAddrP` field applies only to datagram sockets without an existing connection. An error is returned if the datagram socket was previously connected and `toAddrP` is specified. Stream-based sockets, by definition, must have a connection established with a remote host before data can be written. Raw sockets (supported in Palm OS version 3.0 and higher) must construct the entire IP header, including the destination address, before data can be sent; thus, the address is taken from the data to be sent.

If there isn't enough buffer space to send any data, this call will block until there is space, or until a timeout.

---

**NOTE:** For stream-based sockets, this call may write only a portion of the desired data. It always returns the number of bytes actually written. Consequently, the caller should be prepared to call this routine repeatedly until the desired number of bytes have been written, or until it returns 0 or -1.

---

[`NetLibDmReceive\(\)`](#)

## NetLibSettingGet Function

<b>Purpose</b>	Retrieves a general setting.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<pre>Err NetLibSettingGet (UInt16 libRefNum,                      UInt16 setting, void *valueP,                      UInt16 *valueLenP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>setting</i> Setting to retrieve, one of the <code>NetSettingEnum</code> constants.</p> <p>← <i>valueP</i> Space for return value of setting.</p>

↔ *valueLenP*

On entry, size of *valueP*. On exit, actual size of setting.

**Returns** Returns one of the following values:

0

Success.

*netErrUnknownSetting*

Invalid setting constant

*netErrPrefNotFound*

No current value for setting

*netErrBufTooSmall*

*valueP* was too small to hold entire setting. Setting value was truncated to fit in *valueP*.

*netErrBufWrongSize*

**Sockets  
Equivalent**

None

**Comments**

This call retrieves the current value of any general setting. The caller must pass a pointer to a buffer to hold the return value (*valueP*), the size of the buffer (*\*valueLenP*), and the setting ID (*setting*). The setting ID is one of the *NetSettingEnum* constants in the *netSettingEnum* type.

Some settings, such as the host table, are variable size. For these types of settings, you can obtain the actual size required for the buffer by passing 0 for *\*valueLenP*. The required size is returned in *valueLenP*.

[Table 61.3](#) lists the general settings and the type of each setting.

**Table 61.3 Net Library General Settings**

<b>netSetting...</b>	<b>Type</b>	<b>Description</b>
ResetAll	void	Used for <a href="#">NetLibSettingSet()</a> only. This will clear all other settings to their default values.
PrimaryDNS	UInt32	IP address of primary DNS server. This setting must be set to a non-zero IP address in order to support any of the name lookup calls.
SecondaryDNS	UInt32	IP address of secondary DNS server. Set to 0 to have stack ignore this setting.
DefaultRouter	UInt32	IP address of default router. Default value is 0 which is appropriate for most implementations with only one attached interface (besides loopback). Packets with destination IP addresses that don't lie in the subnet of an attached interface will be sent to this router through the default interface specified by the <code>netSettingDefaultIFCreator/</code> <code>netSettingDefaultIFInstance</code> pair.
DefaultIFCreator	UInt32	Creator of the default network interface. Default value is 0, which is appropriate for most implementations. Packets with destination IP addresses that don't lie in the subnet of a directly attached interface are sent through this interface. If this setting is 0, the stack automatically makes the first non-loopback interface the default interface.
DefaultIFInstance	UInt16	Instance number of the default network interface. Packets with destination IP addresses that don't lie in the subnet of an attached interface are sent through the default interface. Default value is 0.
HostName	Char []	A zero-terminated character string of 64 bytes or less containing the host name of this machine. This setting is not actually used by the stack. It's present mainly for informative purposes and to support the <code>gethostname/sethostname</code> sockets API calls. To clear the host name, call <a href="#">NetLibIFSettingSet()</a> with a <code>valueLen</code> of 0.

**Table 61.3 Net Library General Settings (*continued*)**

netSetting...	Type	Description
DomainName	Char []	A zero-terminated character string of 256 bytes or less containing the default domain. This default domain name is appended to all host names before name lookups are performed. If the name is not found, the host name is looked up again without appending the domain name to it. To have the stack not use the domain name, call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0.
HostTbl	Char []	A null-terminated character string containing the host table. This table is consulted first before sending a DNS query to the DNS server(s). To have the stack not use a host table, call <a href="#">NetLibIFSettingSet()</a> with a valueLen of 0. The format of a host table is a series of lines separated by '\n' in the following format:  host.company.com A 111.222.333.444
CloseWaitTime	UInt32	The close-wait time in milliseconds. This setting must be specified. See the discussion of the <a href="#">NetLibClose()</a> call for an explanation of the close-wait time.
TraceBits	UInt32	A bitfield of various trace bits. See " <a href="#">Tracing Bits</a> ." Default value is (netTracingErrors   netTracingAppMsgs). An application can get a list of events in the trace buffer using the <a href="#">NetLibMaster()</a> call.
TraceSize	UInt32	Maximum trace buffer size in bytes. Setting this setting always clears the existing trace buffer. Default is 2 KB.
TraceRoll	UInt8	Boolean value, default is true (non-zero). If true, trace buffer will roll over when it fills. If false, tracing will stop as soon as trace buffer fills.

[NetLibIFSettingGet\(\)](#), [NetLibMaster\(\)](#)

## NetLibSettingSet Function

<b>Purpose</b>	Sets a general setting.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Err NetLibSettingSet (UInt16 libRefNum,                      UInt16 setting, void *valueP, UInt16 valueLen)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>setting</i> Setting to set; one of the NetSettingEnum constants. See <a href="#">Table 61.3</a>.</p> <p>→ <i>valueP</i> New value for the setting.</p> <p>→ <i>valueLen</i> Size of new setting.</p>
<b>Returns</b>	<p>Returns one of the following values:</p> <p>0 Success.</p> <p>netErrUnknownSetting Invalid setting constant.</p> <p>netErrInvalidSettingSize valueLen was invalid for the given setting.</p> <p>netErrBufWrongSize</p> <p>netErrReadOnlySetting</p>
<b>Sockets Equivalent</b>	None
<b>Comments</b>	<p>This call can be used to set the current value of any general setting. The caller must pass a pointer to a buffer which holds the new value (<i>valueP</i>), the size of the buffer (<i>valueLen</i>), and the setting ID (<i>setting</i>). The setting ID is one of the <code>netSettingXXX</code> constants in the <code>NetSettingEnum</code> type.</p> <p>If the net library is not open at the time this call is made, the setting is stored in the active configuration. You need to save the active configuration using <a href="#">NetLibConfigSaveAs()</a> if you want the new</p>

value of the setting to be used the next time the net library is opened.

See [NetLibSettingGet\(\)](#) for an explanation of each of the settings.

Of particular interest is the `netSettingResetAll` setting, which, if used, will reset all general settings to their default values. When using this setting, `valueP` and `valueLen` are ignored.

**See Also**    [NetLibSettingGet\(\)](#), [NetLibSettingSet\(\)](#),  
[NetLibIFSettingSet\(\)](#), [NetLibMaster\(\)](#)

## NetLibSocketAccept Function

<b>Purpose</b>	Accept a connection from a stream-based socket.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<pre>Int16 NetLibSocketAccept (UInt16 libRefnum,                           NetSocketRef socket,                           NetSocketAddrType *sockAddrP,                           Int16 *addrLenP, Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<div><div>→ <i>libRefNum</i> Reference number of the net library.</div><div>→ <i>socket</i> Descriptor for the open socket.</div><div>← <i>sockAddrP</i> Address of remote host is returned here.</div><div>↔ <i>addrLenP</i> On entry, length of <i>sockAddrP</i> buffer in bytes. On exit, length of returned address stored in <i>*sockAddrP</i>.</div><div>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</div><div>← <i>errP</i> Contains an error code if the return value is -1.</div></div>
<b>Returns</b>	Returns the <code>NetSocketRef</code> of the new socket. If the return value is -1, an error has occurred, and <i>errP</i> contains one of the following values:

0

No error.

netErrTimeout

Call timed out.

netErrNotOpen

The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrSocketNotConnected

netErrSocketClosedByRemote

netErrWrongSocketType

netErrSocketNotListening

netErrUnimplemented

**Sockets  
Equivalent**

```
int accept (int socket, void *sockAddrP,  
int *addrLenP);
```

**Comments**

Accepts the next connection request from a remote client. This call is only applicable to stream-based sockets. Before calling `NetLibSocketAccept` on a socket, a server application needs to:

- Open the socket ([NetLibSocketOpen\(\)](#)).
- Bind the socket to a local address ([NetLibSocketBind\(\)](#)).
- Set the maximum pending connection-request queue length ([NetLibSocketListen\(\)](#)).

`NetLibSocketAccept` will block until a successful connection request is obtained from a remote client. After a successful connection is made, this call returns with the address of the remote host in `*sockAddrP` and the socket descriptor of a **new** socket as the return value. You then use the new socket to send and receive data.

**See Also**

[NetLibSocketBind\(\)](#), [NetLibSocketListen\(\)](#)

## NetLibSocketAddr Function

<b>Purpose</b>	Returns the local and remote addresses currently associated with a socket.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<pre>Int16 NetLibSocketAddr (UInt16 libRefnum,                         NetSocketRef socketRef,                         NetSocketAddrType *locAddrP,                         Int16 *locAddrLenP,                         NetSocketAddrType *remAddrP,                         Int16 *remAddrLenP,                         Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>socketRef</i> Descriptor for the open socket.</p> <p>← <i>locAddrP</i> Local address of socket is returned here.</p> <p>↔ <i>locAddrLenP</i> On entry, length of <i>locAddrP</i> buffer in bytes. On exit, length of returned address stored in <i>*locAddrP</i>.</p> <p>← <i>remAddrP</i> Address of remote host is returned here.</p> <p>↔ <i>remAddrLenP</i> On entry, length of <i>remAddrP</i> buffer in bytes. On exit, length of returned address stored in <i>*remAddrP</i>.</p> <p>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</p> <p>← <i>errP</i> Contains an error code if the return value is -1.</p>
<b>Returns</b>	<p>Returns 0 upon success and -1 if an error occurred. If the return value is -1, <i>errP</i> contains one of the following values:</p> <p>0 No error.</p> <p><code>netErrTimeout</code> Call timed out.</p>

netErrNotOpen

The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrSocketClosedByRemote

netErrOutOfCmdBlocks

**Sockets  
Equivalent**

```
int getpeername (int s, struct sockaddr *name,  
int *namelen);
```

```
int getsockname (int s, struct sockaddr *name,  
int *namelen);
```

**Comments**

This call is mainly useful for stream-based sockets. It allows the caller to find out what address was bound to a connected socket and the address of the remote host that it's connected to.

In Palm OS version 3.0 and higher, if you pass a raw socket to this function, it returns the instance number and creator of the interface to which the socket is bound.

**See Also**

[NetLibSocketBind\(\)](#), [NetLibSocketConnect\(\)](#),  
[NetLibSocketAccept\(\)](#)

## NetLibSocketBind Function

**Purpose**

Assign a local address to a socket.

**Declared In**

NetMgr.h

**Prototype**

```
Int16 NetLibSocketBind (UInt16 libRefnum,  
NetSocketRef socket,  
NetSocketAddrType *sockAddrP,  
Int16 addrLen, Int32 timeout, Err *errP)
```

**Parameters**

→ *libRefNum*

Reference number of the net library.

→ *socket*

Descriptor for the open socket.

→ *sockAddrP*

Pointer to the address to give to the socket. This can be a [NetSocketAddrIntType](#) or a [NetSocketAddrRawType](#).

→ *addrLen*

Length of address in \*sockAddrP.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *errP*

Contains an error code if the return value is -1.

**Returns** Returns 0 upon success and -1 if an error occurred. If an error occurred, *errP* contains one of the following values:

0

No error.

*netErrTimeout*

Call timed out.

*netErrNotOpen*

The referenced net library has not been opened yet.

*netErrParamErr*

*netErrSocketNotOpen*

*netErrSocketAlreadyConnected*

*netErrSocketClosedByRemote*

*netErrOutOfCmdBlocks*

**Sockets  
Equivalent**

`int bind (int socket, const void *sockAddrP,  
int addrLen);`

**Comments**

Applications that want to wait for an incoming connection request from a remote host must call this function. After calling `NetLibSocketBind`, applications can call [NetLibSocketListen\(\)](#) and then [NetLibSocketAccept\(\)](#) to make the socket ready to accept connection requests.

**Compatibility**

Raw sockets are only supported in Palm OS version 3.0 and higher. See [NetLibSocketOpen\(\)](#) for instructions on how to bind raw sockets.

**See Also**

[NetLibSocketConnect\(\)](#), [NetLibSocketListen\(\)](#),  
[NetLibSocketAccept\(\)](#)

## NetLibSocketClose Function

<b>Purpose</b>	Close a socket.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	Int16 NetLibSocketClose (UInt16 libRefnum, NetSocketRef socket, Int32 timeout, Err *errP)
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>socket</i> Descriptor for the open socket.</p> <p>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</p> <p>← <i>errP</i> Contains an error code if the return value is -1.</p>
<b>Returns</b>	<p>Returns 0 upon success and -1 if an error occurred. If an error occurred, <i>errP</i> contains one of the following values:</p> <p>0 No error.</p> <p>netErrTimeout Call timed out.</p> <p>netErrNotOpen The referenced net library has not been opened yet.</p> <p>netErrParamErr</p> <p>netErrSocketNotOpen</p> <p>netErrOutOfCmdBlocks</p>
<b>Sockets Equivalent</b>	<code>int close (int socket);</code>
<b>Comments</b>	Closes down a socket and frees all memory associated with it.
<b>See Also</b>	<a href="#">NetLibSocketOpen()</a> , <a href="#">NetLibSocketShutdown()</a>

## NetLibSocketConnect Function

<b>Purpose</b>	Assign a destination address to a socket and initiate three-way handshake if it's stream based.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Int16 NetLibSocketConnect (UInt16 libRefnum,     NetSocketRef socket,     NetSocketAddrType *sockAddrP,     Int16 addrLen, Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>socket</i> Descriptor for the open socket.</p> <p>→ <i>sockAddrP</i> Pointer to address to connect to.</p> <p>→ <i>addrLen</i> Length of address in *sockAddrP.</p> <p>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</p> <p>← <i>errP</i> Contains an error code if the return value is -1.</p>
<b>Returns</b>	<p>Returns 0 upon success and -1 if an error occurred. If an error occurred, <i>errP</i> contains one of the following values:</p> <p>0 No error.</p> <p>netErrTimeout Call timed out.</p> <p>netErrNotOpen The referenced net library has not been opened yet.</p> <p>netErrParamErr</p> <p>netErrSocketNotOpen</p> <p>netErrSocketBusy</p> <p>netErrNoInterfaces Incorrect setup.</p>

`netErrPortInUse`  
`netErrQuietTimeNotElapsed`  
`netErrInternal`  
`netErrSocketAlreadyConnected`  
`netErrSocketClosedByRemote`  
`netErrTooManyTCPConnections`  
`netErrWouldBlock`  
`netErrWrongSocketType`  
`netErrOutOfCmdBlocks`

**Sockets Equivalent** `int connect (int socket, const void *sockAddrP, int addrLen);`

**See Also** [NetLibSocketBind\(\)](#), [NetUTCPOpen\(\)](#)

## NetLibSocketListen Function

**Purpose** Put a stream-based socket into passive listen mode.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSocketListen (UInt16 libRefnum, NetSocketRef socket, UInt16 queueLen, Int32 timeout, Err *errP)`

**Parameters**

- `→ libRefNum`  
Reference number of the net library.
- `→ socket`  
Descriptor for the open socket.
- `→ queueLen`  
Maximum number of pending connections allowed.
- `→ timeout`  
Maximum timeout in system ticks; -1 means wait forever.
- `← errP`  
Contains an error code if the return value is -1.

**Returns** Returns 0 upon success and -1 if an error occurred. If an error occurred, `errP` contains one of the following values:

0  
    No error.

netErrTimeout  
    Call timed out.

netErrNotOpen  
    The referenced net library has not been opened yet.

netErrParamErr

netErrOutOfResources

netErrSocketNotOpen

netErrSocketBusy

netErrNoInterfaces  
    Incorrect setup.

netErrPortInUse

netErrInternal

netErrSocketAlreadyConnected

netErrSocketClosedByRemote

netErrWrongSocketType

netErrQuietTimeNotElapsed

netErrOutOfCmdBlocks

**Sockets  
Equivalent**

**Comments**

int listen (int socket, int queueLen);

Sets the maximum allowable length of the queue for pending connections. This call is only applicable to stream-based (TCP/IP) sockets.

After a socket is created and bound to a local address using [NetLibSocketBind\(\)](#), a server application can call [NetLibSocketListen](#) and then [NetLibSocketAccept\(\)](#) to accept connections from remote clients.

The queueLen is currently quietly limited to 1 (higher values are ignored).

**See Also**    [NetLibSocketBind\(\)](#), [NetLibSocketAccept\(\)](#)

## NetLibSocketOpen Function

<b>Purpose</b>	Open a new socket.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>NetSocketRef NetLibSocketOpen (UInt16 libRefnum,     NetSocketAddrEnum domain,     NetSocketTypeEnum type,     Int16 protocol, Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>domain</i> Address domain. See <a href="#">NetSocketAddrEnum</a>.</p> <p>→ <i>type</i> Desired type of connection. See <a href="#">NetSocketTypeEnum</a>.</p> <p>→ <i>protocol</i> Protocol to use. This parameter is currently ignored.</p> <p>For raw sockets in the netSocketAddrINET domain, specify one of the following:</p> <p>netSocketProtoIPTCP</p> <p>netSocketProtoIPUDP</p> <p>netSocketProtoIPRAW</p> <p>For all other socket types or for raw sockets in the raw domain, this parameter is ignored.</p> <p>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</p> <p>← <i>errP</i> Contains an error code if the return value is -1.</p>
<b>Returns</b>	<p>Returns the NetSocketRef of the opened socket or -1 if an error occurred. If an error occurred, errP contains one of the following values:</p> <p>0 No error.</p> <p>netErrTimeout Call timed out.</p>

`netErrNotOpen`

The referenced net library has not been opened yet.

`netErrParamErr`

`netErrNoMoreSockets`

`netErrOutOfCmdBlocks`

`netErrOutOfMemory`

**Sockets  
Equivalent  
Comments**

`int socket (int domain, int type, int protocol);`

Allocates memory for a new socket and opens it.

Raw sockets are supported in Palm OS version 3.0 and higher. Two types of raw sockets are supported:

- Raw sockets in the `netSocketAddrINET` domain

In this case, you must bind the socket to an IP address using [NetLibSocketBind\(\)](#), passing a [NetSocketAddrINTType](#) structure for the socket address. The port field is ignored.

For applications that use raw sockets in the INET domain, the net library checks the destination IP address of all incoming packets to see if it matches any of those raw sockets. If it does, the packet is enqueued directly into the matching socket and is **not** passed to the protocol stack.

When an application sends data through raw sockets in the IP domain, the net library packages the data into a packet and passes it directly to the interface's send routine. You are responsible for forming the entire IP header, including any necessary checksums, source and destination IP address, and so on.

- Raw sockets in the `netSocketAddrRaw` domain with no protocol

In this case, you must bind the socket to an interface using [NetLibSocketBind\(\)](#), passing a [NetSocketAddrRawType](#) structure for the socket address. The instance and creator specify which interface the caller wants to receive raw packets from.

When an interface is bound to a raw socket with no protocol, the net library places that interface into raw mode. In raw

## Net Library

### *NetLibSocketOptionGet*

---

mode, the interface passes all incoming packets, no matter what the link layer protocol, to its raw receive function.

When an application sends data through a raw socket with no protocol, the net library packages the data into a packet and passes it directly to the interface's send routine.

The interface remains in raw mode until the raw socket is closed.

**Compatibility** Raw sockets supported only in Palm OS version 3.0 and higher.

**See Also** [NetLibSocketClose\(\)](#), [NetUTCPOpen\(\)](#)

## NetLibSocketOptionGet Function

**Purpose** Retrieves the current value of a socket option.

**Declared In** NetMgr.h

**Prototype**

```
Int16 NetLibSocketOptionGet (UInt16 libRefnum,
                             NetSocketRef socket, UInt16 level,
                             UInt16 option,
                             void *optValueP, UInt16 *optValueLenP,
                             Int32 timeout, Err *errP)
```

**Parameters**

- *libRefNum*  
Reference number of the net library.
- *socket*  
Descriptor for the open socket.
- *level*  
Level of the option, one of the NetSocketOptLevelEnum constants. See [NetLibSocketOptionSet\(\)](#).
- *option*  
One of the NetSocketOptEnum constants. See [NetLibSocketOptionSet\(\)](#).
- ← *optValueP*  
Pointer to variable holding new value of option.
- ↔ *optValueLenP*  
Size of variable pointed to by optValueP on entry. Actual size of return value on exit.

→ *timeout*

Maximum timeout in system ticks; -1 means wait forever.

← *errP*

Contains an error code if the return value is -1.

**Returns** Returns 0 upon success and -1 if an error occurred. If an error occurred, *errP* contains one of the following values:

0

No error.

*netErrTimeout*

Call timed out.

*netErrNotOpen*

The referenced net library has not been opened yet.

*netErrParamErr*

*netErrSocketNotOpen*

*netErrUnimplemented*

*netErrWrongSocketType*

*netErrInvalidSettingSize*

**Sockets  
Equivalent**

```
int getsockopt (int socket, int level, int option,
               const void *optValueP, int *optValueLenP);
```

**Comments**

Returns the current value of a socket option. The caller passes a pointer to a variable to hold the returned value (in *optValueP*) and the size of this variable (in *\*optValueLenP*). On exit, *\*optValueP* is updated with the actual size of the return value.

For all of the fixed size options (every option except *netSocketOptIPOptions*), *\*optValueLenP* is unmodified on exit and this call does its best to return the value in the caller's desired type size.

For compatibility with existing Internet applications, this call is quite flexible on the *\*optValueLenP* parameter. If the desired type for an option is *FLAG*, this call supports an *\*optValueLenP* of 1, 2, or 4. If the desired type for an option is *int*, it supports an *\*optValueLenP* of 2 or 4.

See [NetLibSocketOptionSet\(\)](#) for a list of available options.

**See Also** [NetLibSocketOptionSet\(\)](#)

## NetLibSocketOptionSet Function

<b>Purpose</b>	Set a socket option.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Int16 NetLibSocketOptionSet (UInt16 libRefnum,     NetSocketRef socket, UInt16 level,     UInt16 option,     void *optValueP, UInt16 optValueLen,     Int32 timeout, Err *errP)</pre>
<b>Parameters</b>	<ul style="list-style-type: none"><li>→ <i>libRefNum</i> Reference number of the net library.</li><li>→ <i>socket</i> Descriptor for the open socket.</li><li>→ <i>level</i> Level of the option, one of the NetSocketOptLevelEnum constants. See the comments section.</li><li>→ <i>option</i> One of the NetSocketOptEnum constants. See the comments section.</li><li>→ <i>optValueP</i> Pointer to the variable holding the new value of the option.</li><li>→ <i>optValueLen</i> Size of variable pointed to by <i>optValueP</i>.</li><li>→ <i>timeout</i> Maximum timeout in system ticks; -1 means wait forever.</li><li>← <i>errP</i> Contains an error code if the return value is -1.</li></ul>
<b>Returns</b>	<p>Returns 0 upon success and -1 if an error occurred. If an error occurred, <i>errP</i> contains one of the following values:</p> <ul style="list-style-type: none"><li>0 No error.</li><li>netErrTimeout Call timed out.</li><li>netErrNotOpen The referenced net library has not been opened yet.</li><li>netErrParamErr</li></ul>

```

netErrSocketNotOpen
netErrUnimplemented
netErrWrongSocketType
netErrInvalidSettingSize

Sockets
Equivalent
Comments
int setsockopt (int socketRef, int level,
int option, const void *optValueP,
int optValueLen);
Sets various options associated with a socket. The caller passes a
pointer to the new option value in optValueP and the size of the
option in optValueLen.

```

[Table 61.4](#) lists the available options.

- The Level column specifies the option level, which is one of the netSocketOptLevelXXX constants.
- The Option column lists the option, which is one of the netSocketOptXXX constants.
- The G/S column lists whether this option can be fetched with the [NetLibSocketOptionGet\(\)](#) call (G) and/or set (S) with this call.
- The type column lists the data type of the option.
- The I column specifies whether or not this option is currently implemented.

**Table 61.4 Net Library Socket Options**

netSocket OptLevel...	netSocketOpt...	G/S	Type	I	Description
IP	IPOptions	GS	UInt8 []	N	Options in IP Header
TCP	TCPNoDelay	GS	FLAG	Y	Don't delay send to coalesce packets
TCP	TCPMaxSeg	G	int	Y	Get TCP maximum segment size
Socket	SockDebug	GS	FLAG	N	Turn on recording of debug info
Socket	SockAcceptConn	G	FLAG	N	Socket has had listen

**Table 61.4 Net Library Socket Options (*continued*)**

<b>netSocket OptLevel...</b>	<b>netSocketOpt...</b>	<b>G/S</b>	<b>Type</b>	<b>I</b>	<b>Description</b>
Socket	SockReuseAddr	GS	FLAG	N	Allow local address reuse
Socket	SockKeepAlive	GS	FLAG	Y	Keep connections alive
Socket	SockDontRoute	GS	FLAG	N	Just use interface addresses
Socket	SockBroadcast	GS	FLAG	N	Permit sending of broadcast messages
Socket	SockUseLoopback	GS	FLAG	N	Bypass hardware when possible
Socket	SockLinger	GS	NetSocketLingerType	Y	Linger on close if data present  NetSocketLingerType is a structure with two fields: onOff (true or false) and time (linger time in seconds).
Socket	SockOOBInLine	GS	FLAG	N	Leave received OOB data in-line
Socket	SockSndBufSize	GS	int	N	Send buffer size
Socket	SockRcvBufSize	GS	int	N	Receive buffer size
Socket	SockSndLowWater	GS	int	N	Send low-water mark
Socket	SockRcvLowWater	GS	int	N	Receive low-water mark
Socket	SockSndTimeout	GS	int	N	Send timeout
Socket	SockRcvTimeout	GS	int	N	Receive timeout
Socket	SockErrorStatus	G	int	Y	Get error status and clear

**Table 61.4 Net Library Socket Options (*continued*)**

<b>netSocket OptLevel...</b>	<b>netSocketOpt...</b>	<b>G/S</b>	<b>Type</b>	<b>I</b>	<b>Description</b>
Socket	SockSocketType	G	int	Y	Get socket type
Socket	SockNonBlocking	GS	FLAG	Y	Set non-blocking mode on/off
Socket	SockRequireErrClear	GS	FLAG	Y	Return the current error status for all subsequent socket function calls until the error is cleared.

For compatibility with existing Internet applications, this call is quite flexible on the `optValueLen` parameter. If the desired type for an option is `FLAG`, this call accepts an `optValueLen` of 1, 2, or 4. If the desired type for an option is `int`, it accepts an `optValueLen` of 2 or 4.

Except for the `netSocketOptSockNonBlocking` option, all options listed above have equivalents in the sockets API. The `netSocketOptSockNonBlocking` option was added to this call in the net library in order to implement the functionality of the UNIX `fcntl()` control call, which can be used to turn nonblocking mode on and off for sockets.

**See Also**    [NetLibSocketOptionGet\(\)](#)

## NetLibSocketShutdown Function

**Purpose**        Shut down a socket in one or both directions.

**Declared In**   `NetMgr.h`

**Prototype**    `Int16 NetLibSocketShutdown (UInt16 libRefnum,  
                                  NetSocketRef socket, Int16 direction,  
                                  Int32 timeout, Err *errP)`

**Parameters**     $\rightarrow$  `libRefNum`  
                  Reference number of the net library.

→ *socket*  
 Descriptor for the open socket.

→ *direction*  
 Direction to shut down. One of the NetSocketDirEnum constants. Specifically:  
 netSocketDirInput  
 netSocketDirOutput  
 netSocketDirBoth

→ *timeout*  
 Maximum timeout in system ticks; -1 means wait forever.

← *errP*  
 Contains an error code if the return value is -1.

**Returns** Returns 0 upon success and -1 if an error occurred. If an error occurred, *errP* contains one of the following values:

0  
 No error.

netErrTimeout  
 Call timed out.

netErrNotOpen  
 The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrNoMultiPktAddr

netErrOutOfCmdBlocks

**Sockets Equivalent** `int shutdown (int socket, int direction);`

**Comments** Shuts down communication in one or both directions on a socket.

If *direction* is `netSocketDirInput`, the socket is marked as down in the receive direction and further read operations from it return a `netErrSocketInputShutdown` error.

## NetLibTracePrintf Function

<b>Purpose</b>	Store debugging information in the net library's trace buffer.
<b>Declared In</b>	NetMgr.h
<b>Prototype</b>	<pre>Err NetLibTracePrintf (UInt16 libRefNum,     const Char *formatStr, ...)</pre>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>formatStr</i> A printf style format string.</p> <p>→ ... Arguments to the format string.</p>
<b>Returns</b>	Returns 0 upon success or netErrNotOpen if the net library has not been opened.
<b>Sockets Equivalent</b>	None
<b>Comments</b>	<p>This call is a convenient debugging tool for developing Internet applications. It stores a message into the net library's trace buffer, which can later be dumped using the <a href="#">NetLibMaster()</a> call. The net library's trace buffer is used to store run-time errors that the net library encounters as well as errors and messages from network interfaces and from applications that use this call.</p> <p>The <i>formatStr</i> parameter is a printf style format string which supports the following format specifiers:</p> <p><code>%d, %i, %u, %x, %s, %c</code></p> <p>but it does <b>not</b> support field widths, leading 0's etc.</p> <p>Note that the <code>netTracingAppMsgs</code> bit of the <code>netSettingTraceBits</code> setting must be set using the call <code>NetLibSettingSet(...netSettingTraceBits...)</code>. Otherwise, this routine will do nothing.</p>
<b>See Also</b>	<a href="#">NetLibTracePutS()</a> , <a href="#">NetLibMaster()</a> , <a href="#">NetLibSettingSet()</a>

## NetLibTracePutS Function

<b>Purpose</b>	Store debugging information in the net library's trace buffer.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<code>Err NetLibTracePutS (UInt16 libRefNum, Char *strP)</code>
<b>Parameters</b>	<p>→ <i>libRefNum</i> Reference number of the net library.</p> <p>→ <i>strP</i> String to store in the trace buffer.</p>
<b>Returns</b>	Returns 0 upon success or <code>netErrNotOpen</code> if the net library has not been opened.
<b>Sockets Equivalent</b>	None
<b>Comments</b>	<p>This call is a convenient debugging tool for developing Internet applications. It will store a message into the net library's trace buffer which can later be dumped using the <a href="#">NetLibMaster()</a> call. The net library's trace buffer is used to store run-time errors that the net library encounters as well as errors and messages from network interfaces and from applications that use this call.</p> <p>Note the <code>netTracingAppMsgs</code> bit of the <code>netSettingTraceBits</code> setting must be set using the <code>NetLibSettingSet(...netSettingTraceBits...)</code> call or this routine will do nothing.</p>
<b>See Also</b>	<a href="#">NetLibTracePrintf()</a> , <a href="#">NetLibMaster()</a> , <a href="#">NetLibSettingSet()</a>

## NetNToHL Macro

<b>Purpose</b>	Converts a 32-bit value from network to host byte order.
<b>Declared In</b>	<code>NetBitUtils.h</code>
<b>Prototype</b>	<code>#define NetNToHL (x)</code>
<b>Parameters</b>	<p>→ <i>x</i> 32-bit value to convert.</p>
<b>Returns</b>	Returns <i>x</i> in host byte order.

**Errors** none  
**Sockets Equivalent** ntohl()  
**See Also** [NetNToHS\(\)](#), [NetHToNL\(\)](#), [NetHToNS\(\)](#)

## NetNToHS Macro

**Purpose** Converts a 16-bit value from network to host byte order.  
**Declared In** NetBitUtils.h  
**Prototype** #define NetNToHS (x)  
**Parameters** → x  
16-bit value to convert.  
**Returns** Returns x in host byte order.  
**Errors** None  
**Sockets Equivalent** ntohs()  
**See Also** [NetHToNL\(\)](#), [NetNToHL\(\)](#), [NetHToNS\(\)](#)

# Network Utilities

---

This chapter describes network utilities provided in the module `NetSocket.c`. These utilities are convenience functions that you can use in place of net library functions in applications that use the net library. You can find `NetSocket.c` in the folder `Libraries\Net\Src`. (On Palm OS® 3.5, `NetSocket.c` is in the folder `CodeWarrior Libraries\Comms\NetSocket\Src`.)

The include file for the functions described in this chapter is `<unix/sys_socket.h>`. This header file is not included by any other Palm™ header file; you must explicitly include it in your code.

For more information on `NetSocket.c` and `sys_socket.h`, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Network Utility Functions

### NetUReadN Function

<b>Purpose</b>	Reads a specified number of bytes from a socket.
<b>Declared In</b>	<code>unix/sys_socket.h</code>
<b>Prototype</b>	<code>Int32 NetUReadN (NetSocketRef fd, UInt8* bufP, UInt32 numBytes)</code>
<b>Parameters</b>	<p>→ <i>fd</i> Descriptor for the open socket.</p> <p>← <i>bufP</i> Pointer to buffer to hold received data.</p> <p>→ <i>numBytes</i> Number of bytes to read.</p>
<b>Returns</b>	Returns the number of bytes actually read. If the return value is less than 0, an error occurred.

## Network Utilities

### *NetUTCPOpen*

---

**Comments** This function repeatedly calls [NetLibReceive\(\)](#) until numBytes have been read or until NetLibReceive returns an error.

**See Also** [NetUWriteN\(\)](#)

## NetUTCPOpen Function

**Purpose** Opens a TCP (streams-based) socket and connects it to a server.

**Declared In** `unix/sys_socket.h`

**Prototype** `NetSocketRef NetUTCPOpen (Char* hostName,  
Char* serviceName, Int16 port)`

**Parameters**

- *hostName*  
Remote host, given either by name or by dotted decimal address.
- *serviceName*  
The name of a network service. Possible services are “echo”, “discard”, “daytime”, “qotd”, “chargen”, “ftp-data”, “ftp”, “telnet”, “smtp”, “time”, “name”, “finger”, “pop2”, “pop3”, “nntp”, “imap2”. The value of this parameter is ignored if the port parameter is greater than zero.
- *port*  
The number of the port to connect to on the remote host. Set port to zero to use serviceName instead.

**Returns** Returns the socket descriptor of the socket that was connected, or -1 if an error occurred.

**Comments** If serviceName is given and port is less than or equal to zero, this function looks up the port number for that service on the remote host and uses it for the connection.

This function is the equivalent of calling [NetLibSocketOpen\(\)](#) and [NetLibSocketConnect\(\)](#) (or socket and connect).

---

**NOTE:** This function does not return specific reasons for failure if there is a failure. This function is not production-quality code. It is provided as a quick and dirty way of creating a connection and as sample code that can be used as a reference.

---

## NetUWriteN Function

<b>Purpose</b>	Writes the specified number of bytes to a socket.
<b>Declared In</b>	<code>unix/sys_socket.h</code>
<b>Prototype</b>	<code>Int32 NetUWriteN (NetSocketRef fd, UInt8* bufP, UInt32 numBytes)</code>
<b>Parameters</b>	<div><div><code>→ fd</code> Descriptor for the open socket.</div><div><code>→ bufP</code> Pointer to buffer to write.</div><div><code>→ numBytes</code> Number of bytes to write.</div></div>
<b>Returns</b>	Returns the number of bytes actually sent. If the return value is less than 0, an error occurred.
<b>Comments</b>	This function repeatedly calls <a href="#">NetLibSend()</a> until numBytes have been written or until NetLibSend returns an error.
<b>See Also</b>	<a href="#">NetUReadN</a>

## **Network Utilities**

*NetUWriteN*

---

# Script Plugin

---

This chapter describes the login script plugin support. You write a plugin to add to the list of available login script commands in the Network preferences panel. This chapter covers:

- [Script Plugin Data Types](#)
- [Script Plugin Constants](#)

The header file `ScriptPlugin.h` declares the API described in this chapter.

For more information on the script plugin, see the section “[Extending the Network Login Script Support](#)” on page 182 in the “[Network Communication](#)” chapter of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Script Plugin Data Types

### PluginCallbackProcType Struct

**Purpose** The `PluginCallbackProcType` defines the `procP` field in [PluginExecCmdType](#).

**Prototype**

```
typedef struct {
    ScriptPluginSelectorProcPtr selectorProcP;
} PluginCallbackProcType, *PluginCallbackProcPtr;
```

### Field Descriptions

`selectorProcP` The address of a selector-based callback function for accessing the functionality of the network interface. Each network interface provides its own `ScriptPluginSelectorProc` function. See [ScriptPluginSelectorProc\(\)](#).

## PluginCmdPtr Typedef

**Purpose** The PluginCmdPtr type defines a pointer to a [PluginCmdType](#) structure.

**Prototype** `typedef PluginCmdType * PluginCmdPtr;`

## PluginCmdType Struct

**Purpose** The PluginCmdType structure specifies the name of a command.

**Prototype** `typedef struct {  
 Char commandName[pluginMaxCmdNameLen + 1];  
 Boolean hasTxtStringArg;  
 UInt8 reserved;  
} PluginCmdType;`

### Field Descriptions

commandName	The name of the command. This string appears in the pull-down list in the Network preferences panel's script view.  The pull-down list contains all available commands from all plugins. Make sure that your command name is unique and as short as possible.
hasTxtStringArg	true if the command takes an argument. In this case when the user selects this command, the Network preferences panel displays a field next to the command name where the user should enter the argument. This argument is passed in the txtStringArg field in <a href="#">PluginExecCmdType</a> when the command is to be executed.
reserved	Reserved for future use.

## PluginExecCmdType Struct

**Purpose** The `PluginExecCmdType` structure defines the parameter block for the `scptLaunchCmdExecuteCmd` launch code. This structure specifies which command is to be executed and provides any necessary arguments for the command. Your plugin should respond by executing the command.

**Prototype**

```
typedef struct {
    Char    commandName[pluginMaxCmdNameLen + 1];
    Char    txtStringArg
                [pluginMaxLenTxtStringArg + 1];
    PluginCallbackProcPtr procP;
    void *   handle;
} PluginExecCmdType, *PluginExecCmdPtr;
```

### Field Descriptions

<code>commandName</code>	The command's name. This is the string that appears in the pull-down list in the script view of the Network preferences panel.
<code>txtStringArg</code>	If the command takes an argument, this field provides the argument as a string. A <code>NULL</code> value means either that the user did not provide a value, or that you didn't specify that the command takes an argument.
<code>procP</code>	A pointer to a <a href="#">PluginCallbackProcType</a> structure, which identifies the network interface function that the plugin can use to execute the command.
<code>handle</code>	Handle to information specific to a particular connection. You must pass this value when you call the function pointed to by <code>procP</code> .

## PluginInfoPtr Typedef

**Purpose** The `PluginInfoPtr` type defines a pointer to a [PluginInfoType](#) structure.

**Prototype** `typedef PluginInfoType * PluginInfoPtr;`

## PluginInfoType Struct

**Purpose** The `PluginInfoType` structure is the parameter block for the `scptLaunchCmdListCmds` launch code. When your plugin receives the launch code, the `PluginInfoType` structure is empty. Your plugin should fill in the `PluginInfoType` and return it. The system uses the information returned to construct the pull-down list of available script commands and build a table of which plugin will execute which script command.

**Prototype**

```
typedef struct {
    Char  pluginName[pluginMaxModuleNameLen + 1];
    UInt16  numOfCommands;
    PluginCmdType  command[pluginMaxNumOfCmds];
} PluginInfoType;
```

### Field Descriptions

<code>pluginName</code>	A name that the system can use to identify your plugin. This is typically the same name you give the PRC file.
<code>numOfCommands</code>	The number of commands that your plugin defines. The maximum allowed is <code>pluginMaxNumOfCmds</code> .
<code>command</code>	An array of <a href="#">PluginCmdType</a> structures that provide information about the commands that your plugin defines.

## ScriptPluginLaunchCodesEnum Enum

**Purpose** The ScriptPluginLaunchCodesEnum defines the launch codes for the script plugin. Your script plugin's [PilotMain\(\)](#) function should respond to the launch codes defined in this enum.

**Prototype**

```
typedef enum {  
    scptLaunchCmdDoNothing =  
        sysAppLaunchCmdCustomBase,  
    scptLaunchCmdListCmds,  
    scptLaunchCmdExecuteCmd  
} ScriptPluginLaunchCodesEnum;
```

### Value Descriptions

scptLaunchCmdDoNothing	This launch code is a no-op supplied only to provide a beginning value for the script plugin launch codes. It is not necessary to respond to this launch code.
scptLaunchCmdListCmds	Provide information about the commands that your plugin executes. See <a href="#">PluginInfoType</a> .
scptLaunchCmdExecuteCmd	Execute the specified command.  This launch code is received when the system is executing a user's login script during a network connection attempt. Your plugin should respond by executing the command provided in the <a href="#">PluginExecCmdType</a> parameter block.

## Script Plugin Constants

### Command Constants

The following constants identify the available commands that the network interface can perform for you. These commands are building blocks that you use to create your own script commands. To perform one of these tasks, pass the constant value as an argument to the network interface's callback function ([ScriptPluginSelectorProc\(\)](#)).

Constant	Value	Description
<code>pluginNetLibDoNothing</code>	0	For debugging purposes.
<code>pluginNetLibReadBytes</code>	1	Read the specified number of bytes from the open connection.
<code>pluginNetLibWriteBytes</code>	2	Write the specified number of bytes to the open connection.
<code>pluginNetLibGetUserName</code>	3	Get the user name from the network service profile.
<code>pluginNetLibGetUserPwd</code>	4	Get the user's password from the network service profile.
<code>pluginNetLibCheckCancelStatus</code>	5	Check to see if the user canceled the connection.
<code>pluginNetLibPromptUser</code>	6	Prompt the user for input.
<code>pluginNetLibConnLog</code>	7	Write a string to the network service's connection log.
<code>pluginNetLibCallUIProc</code>	8	Have the network interface call a function in your plugin that displays UI.

Constant	Value	Description
		Use this command if you need to display a more complicated user interface than the simple user prompt that the network interface provides.
pluginNetLibGetSerLibRefNum	9	Obtain the serial library's reference number. You need the reference number to perform any serial library commands, which you might need to perform more complex work with the connection port.

## Size Constants

The following table lists constants that control the size of strings in your plugin and the size of the plugin itself.

Constant	Value	Description
pluginMaxCmdNameLen	15	The maximum length for the command's name, not including the terminating null character. This is the string displayed to the user in the pull-down menu.
pluginMaxModuleNameLen	15	The maximum length for the plugin's name (not including the terminating null character), which is typically the name of the PRC file as well.
pluginMaxNumOfCmds	10	The maximum number of commands that your plugin can define.
pluginMaxLenTxtStringArg	63	The maximum length of the argument that each command can take, not including the terminating null character.

## Script Plugin Functions

### ScriptPluginSelectorProc Function

<b>Purpose</b>	A function provided by the network interface for the purpose of performing script commands.
<b>Declared In</b>	ScriptPlugin.h
<b>Prototype</b>	<pre>Err (*ScriptPluginSelectorProcPtr) (void *handle,     UInt16 command, void *dataBufferP,     UInt16 *sizeP, UInt16 *dataTimeoutP,     void *procAddrP);</pre>
<b>Parameters</b>	<ul style="list-style-type: none"><li>→ <i>handle</i> Handle to information specific to a particular connection.</li><li>→ <i>command</i> The command to be executed. See “<a href="#">Command Constants</a>” for a list of possible values. The rest of the parameters to this callback function are interpreted differently based on the value of the <i>command</i> parameter. See the table in the “Comments” section for specifics.</li><li>↔ <i>dataBufferP</i> A pointer to arguments to pass to the command or a pointer to data returned by the command. See the “Comments” section below.</li><li>↔ <i>sizeP</i> The size of <i>dataBufferP</i>.</li><li>→ <i>dataTimeoutP</i> Number of seconds to wait for the command to execute. 0 means wait forever. Applies only to commands that request information from the network.</li><li>→ <i>procAddrP</i> Pointer to a user interface callback function that the network interface should call to complete the function. Used only by <code>pluginNetLibCallUIProc</code>. This function should take one argument of the same type that you pass to <i>dataBufferP</i> and should return <code>void</code>.</li></ul>

**Returns** Returns 0 upon success, or an error condition upon failure. If an error condition is returned, your plugin should stop processing and return the error condition from its [PilotMain\(\)](#).

**Comments** When your plugin receives the `scptLaunchCmdExecuteCmd` launch code, the parameter block contains the command's name, its text string argument (if any), and a pointer to the network interface's callback function. You should use this callback function any time you need to communicate with the network library, the user, or the host computer during execution of your command.

The callback function takes as arguments the handle to information about this connection (which is also passed in the launch code's parameter block), and the command that the service should execute. The rest of the parameters are interpreted differently based on what the value the command argument is. See the table below.

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
DoNothing	N/A	N/A	N/A	N/A
ReadBytes	On return, contains the bytes that were read.	On input, contains the number of bytes to read.  On return, contains the number of bytes actually read.	Number of seconds to wait before timing out the operation.	N/A
WriteBytes	On input, contains the data to send.	On input, contains the number of bytes to send.	Number of seconds to wait for a response before canceling.	N/A

## Script Plugin

*ScriptPluginSelectorProc*

---

pluginNetLib	dataBufferP	sizeP	dataTimeOutP	procAddrP
		On return, contains the number of bytes actually sent.		
UserName	On return, contains the user's name	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
UserPwd	On return, contains the user's password.	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
CheckCancelStatus	On return, the Boolean value true if the user canceled the command, false otherwise.	Size of Boolean.	N/A	N/A
PromptUser	On input, the prompt to display.  On return, the text that the user entered.	On input and on return, the size of the string pointed to by dataBufferP.	N/A	N/A
ConnLog	The string that should be written to the log.	N/A	N/A	N/A

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
		On return, contains the number of bytes actually sent.		
UserName	On return, contains the user's name	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
UserPwd	On return, contains the user's password.	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
CheckCancelStatus	On return, the Boolean value true if the user canceled the command, false otherwise.	Size of Boolean.	N/A	N/A
PromptUser	On input, the prompt to display.  On return, the text that the user entered.	On input and on return, the size of the string pointed to by dataBufferP.	N/A	N/A
ConnLog	The string that should be written to the log.	N/A	N/A	N/A

## Script Plugin

*ScriptPluginSelectorProc*

---

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
CallUIProc	A pointer to a structure to pass to your callback function as a parameter. This structure should contain a handle to the form to be displayed, plus any other necessary information.	N/A	N/A	A pointer to a function in your plugin that displays the form.
GetSerLib RefNum	On return, contains the serial library's reference number.	N/A	N/A	N/A

---

# Virtual Drivers

---

This chapter provides reference material for the Serial Manager virtual device driver API:

- [Driver Data Structures](#)
- [Driver Constants](#)
- [Virtual Driver-Defined Functions](#)
- [Serial Manager Queue Functions](#)

The header files `SerialVdrv.h` and `SerialDrv.h` declare the virtual driver API. For more information on writing device drivers for the Serial Manager, see section “[Writing a Virtual Device Driver](#)” on page 114 in the “[Serial Communication](#)” chapter of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Driver Data Structures

### DrvInfoType Struct

**Purpose** The `DrvInfoType` structure defines information about the serial hardware. It is passed to and filled in by the [DrvEntryPointProcPtr\(\)](#) for a virtual driver.

**Prototype**

```
typedef struct {
    UInt32 drvID;
    UInt32 drvVersion;
    UInt32 maxBaudRate;
    UInt32 handshakeThreshold;
    UInt32 portFlags;
    const Char *portDesc;
    DrvIRQEnum irqType;
    UInt8 multipleEnumerations;
    UInt32 dbCreator;
} DrvInfoType;
```

## Virtual Drivers

### *DrvInfoType*

---

#### Value Descriptions

drvID	4-character creator type, such as 'u328'.
drvVersion	Version of code that works for this hardware. See <a href="#">Driver Version Constants</a> .
maxBaudRate	Maximum baud rate supported by this hardware.
handshakeThreshold	Baud rate at which the use of hardware handshaking is necessary.
portFlags	Bit flags denoting features of this hardware. The flags are described in <a href="#">Port Feature Constants</a> .
portDesc	Pointer to null-terminated string describing this hardware. This string appears in the Connection panel to describe the port to the user (only if the portCncMgrVisible bit in portFlags is set). Can be NULL if the driver contains a resource (of type 'tSTR' and id kPortDescStrID) that supplies this string.
irqType	IRQ line being used for this hardware. For a virtual driver, specify drvIRQNone.
multipleEnumerations	The number of entries in the driver table required for this driver. If 0, the driver has a single entry.
dbCreator	Creator ID of the database containing this driver.

**Compatibility** The multipleEnumerations and dbCreator fields are only defined if [New Serial Manager Feature Set Version 2](#) is present.

## DrvRcvQType Struct

**Purpose** The DrvRcvQType structure defines the virtual driver receive buffer and function pointers to functions that access and save data to the buffer. A pointer to this structure is passed to the [VdrvOpenProcPtr\(\)](#) function. The DrvRHWRcvQPtr type defines a pointer to a DrvRcvQType structure.

**Prototype**

```
typedef struct DrvRcvQType {
    void *rcvQ;
    WriteByteProcPtr qWriteByte;
    WriteBlockProcPtr qWriteBlock;
    GetSizeProcPtr qGetSize;
    GetSpaceProcPtr qGetSpace;
    SignalCheckPtr qSignalCheck;
} DrvRcvQType;

typedef DrvRcvQType *DrvRHWRcvQPtr;
```

### Value Descriptions

rcvQ	Pointer to the receive buffer.
qWriteByte	Function pointer to a function that the virtual driver can use to write one byte to the Serial Manager's receive queue. See the <a href="#">WriteByteProcPtr()</a> function.
qWriteBlock	Function pointer to a function that the virtual driver can use to write a block of bytes to the Serial Manager's receive queue. See the <a href="#">WriteBlockProcPtr()</a> function.
qGetSize	Function pointer to a function that the virtual driver can use to get the total size of the Serial Manager's receive queue. See the <a href="#">GetSizeProcPtr()</a> function.

## Virtual Drivers

### *DrvStatusEnum*

---

qGetSpace	Function pointer to a function that the virtual driver can use to get the available space in the Serial Manager's receive queue. See the <a href="#">GetSpaceProcPtr()</a> function.
qSignalCheck	Function pointer to a function that the virtual driver can use to perform a signal check for the Serial Manager's receive queue. See the <a href="#">SignalCheckPtr()</a> function.

**Compatibility** The qSignalCheck field is only defined if [New Serial Manager Feature Set Version 2](#) is present.

## DrvStatusEnum Enum

**Purpose** The DrvrStatusEnum enumerated type specifies serial status bit flags. Return these enumerated types from the [VdrvStatusProcPtr\(\)](#) call.

**Prototype**

```
typedef enum DrvrStatusEnum {  
    drvrStatusCtsOn = 0x0001,  
    drvrStatusRtsOn = 0x0002,  
    drvrStatusDsrOn = 0x0004,  
    drvrStatusTxFifoFull = 0x0008,  
    drvrStatusTxFifoEmpty = 0x0010,  
    drvrStatusBreakAsserted = 0x0020,  
    drvrStatusDataReady = 0x0040,  
    drvrStatusLineErr = 0x0080  
} DrvrStatusEnum;
```

### Value Descriptions

drvStatusCtsOn	Set if CTS line is active.
drvStatusRtsOn	Set if RTS line is active.
drvStatusDsrOn	Set if DSR is on.
drvStatusTxFifoFull	Set if transmit FIFO is full; cleared if FIFO has space.
drvStatusTxFifoEmpty	Set if transmit FIFO is empty.

<code>drvStatusBreakAsserted</code>	Set if sending break characters is enabled.
<code>drvStatusDataReady</code>	Used by debugger only.
<code>drvStatusLineErr</code>	Used by debugger only.

## SrmRcvQType Struct

**Purpose** The `SrmRcvQType` structure defines the Serial Manager receive queue. This queue is passed as a parameter to the virtual driver.

**Prototype**

```
typedef struct SrmRcvQType {
    UInt32 qStart;
    UInt32 qEnd;
    UInt32 qSize;
    UInt8 *qData;
    void *qPort;
} SrmRcvQType;
```

### Field Descriptions

<code>qStart</code>	The start of the queue.
<code>qEnd</code>	The end of the queue.
<code>qSize</code>	The size of the queue.
<code>qData</code>	The data currently in the queue.
<code>qPort</code>	A pointer to the current foreground port.

**Compatibility** The `SrmRcvQType` structure was previously a private structure. It is declared publicly if [New Serial Manager Feature Set Version 2](#) is present.

## VdrvAPIType Struct

**Purpose** The `VdrvAPIType` structure defines function pointers to the required virtual driver functions. When passed a pointer to this structure in the [DrvEntryPointProcPtr\(\)](#) function, that

## Virtual Drivers

### *VdrvConfigType*

---

function must fill in the pointers to the virtual driver functions appropriately.

**Prototype**

```
typedef struct {  
    VdrvOpenProcPtr drvOpen;  
    VdrvCloseProcPtr drvClose;  
    VdrvControlProcPtr drvControl;  
    VdrvStatusProcPtr drvStatus;  
    VdrvReadProcPtr drvRead;  
    VdrvWriteProcPtr drvWrite;  
    VdrvOpenProcV4Ptr drvOpenV4;  
    VdrvControlCustomProcPtr drvControlCustom;  
} VdrvAPIType;
```

#### Value Descriptions

drvOpen	Pointer to the driver open function.
drvClose	Pointer to the driver close function.
drvControl	Pointer to the driver control function.
drvStatus	Pointer to the driver status function.
drvRead	Pointer to the driver read function.
drvWrite	Pointer to the driver write function.
drvOpenV4	Pointer to the driver open function for <a href="#">New Serial Manager Feature Set Version 2</a> .
drvControlCustom	Pointer to the driver custom control function.

**Compatibility** drvOpenV4 and drvControlCustom are declared if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## VdrvConfigType Struct

**Purpose** The VdrvConfigType structure specifies parameters for opening a serial port. This structure is passed as a parameter to [VdrvOpenProcV4Ptr\(\)](#).

**Prototype**

```
typedef struct VdrvConfigType {
```

```
UInt32 baud;  
UInt32 drvId;  
UInt32 function;  
MemPtr drvDataP;  
UInt16 drvDataSize;  
UInt32 sysReserved1;  
UInt32 sysReserved2;  
} VdrvConfigType;
```

### Field Descriptions

baud	Baud rate at which to open the connection. Serial drivers that do not require baud rates ignore this field.
drvId	Creator ID of the application or library that is using the Serial Manager.

## Virtual Drivers

### *VdrvConfigType*

---

function	<p>The reason why the port was opened. Specify the creator ID of the application that is opening the port or one of the following values:</p> <p><code>serFncUndefined</code> Undefined function. This is the default value for this field.</p> <p><code>serFncPPPSession</code> The connection is to be used for the PPP interface.</p> <p><code>serFncSLIPSession</code> The connection is to be used for the SLIP session.</p> <p><code>serFncDebugger</code> The connection is to be used for a debugging session.</p> <p><code>serFncHotSync</code> The connection is to be used for a HotSync operation.</p> <p><code>serFncConsole</code> The connection is to the debugging console.</p> <p><code>serFncTelephony</code> The connection is to the telephony library.</p> <p>The function field is used by protocols such as USB and Bluetooth that perform different setup tasks based on which type of application is using them. RS-232 drivers ignore this parameter.</p>
drvDataP	Pointer to a driver-specific data block.
drvDataSize	The size of the data block pointed to by <code>drvDataP</code> .
sysReserved1	Reserved for future use.
sysReserved2	Reserved for future use.

**Compatibility** This structure is only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## VdrvCtlOpCodeEnum Enum

**Purpose** The VdrvCtlOpCodeEnum enumerated type specifies a serial control operation. You should handle each of these constants when passed for the `controlCode` parameter to the [VdrvControlProcPtr\(\)](#) call.

**Prototype**

```
typedef enum VdrvCtlOpCodeEnum {  
    vdrvOpCodeNoOp = 0,  
    vdrvOpCodeSetBaudRate = 0x1000,  
    vdrvOpCodeSetSettingsFlags,  
    vdrvOpCodeSetCtsTimeout,  
    vdrvOpCodeClearErr,  
    vdrvOpCodeSetSleepMode,  
    vdrvOpCodeSetWakeupMode,  
    vdrvOpCodeFIFOCount,  
    vdrvOpCodeStartBreak,  
    vdrvOpCodeStopBreak,  
    vdrvOpCodeStartLoopback,  
    vdrvOpCodeStopLoopback,  
    vdrvOpCodeFlushTxFIFO,  
    vdrvOpCodeFlushRxFIFO,  
    vdrvOpCodeSendBufferedData,  
    vdrvOpCodeRcvCheckIdle,  
    vdrvOpCodeEmuSetBlockingHook,  
    vdrvOpCodeGetOptTransmitSize,  
    vdrvOpCodeGetMaxRcvBlockSize,  
    vdrvOpCodeNotifyBytesReadFromQ,  
    vdrvOpCodeSetDTRAsserted,  
    vdrvOpCodeGetDTRAsserted,  
    vdrvOpCodeWaitForConfiguration,  
    vdrvOpCodeGetUSBDeviceDescriptor,  
    vdrvOpCodeGetUSBConfigDescriptor,  
    vdrvOpCodeEnableIRDA,  
    vdrvOpCodeDisableIRDA,  
    vdrvOpCodeEnableUART,  
    vdrvOpCodeDisableUART,  
    vdrvOpCodeRxEnable,  
    vdrvOpCodeRxDisable,  
    vdrvOpCodeLineEnable,  
    vdrvOpCodeEnableUARTInterrupts,  
}
```

## Virtual Drivers

### *VdrvCtlOpCodeEnum*

---

```
vdrvOpCodeDisableUARTInterrupts,  
vdrvOpCodeSetReceiveQueue,  
vdrvOpCodeSaveState,  
vdrvOpCodeRestoreState,  
vdrvOpCodeSetYieldPortCallback,  
vdrvOpCodesetYieldPortRefCon,  
vdrvOpCodeUserDef = 0x2000,  
vdrvOpCodeSystem = 0x7000,  
vdrvOpCodeCustom = 0x8000  
} VdrvCtlOpCodeEnum;
```

### Value Descriptions

<code>vdvrOpCodeSetBaudRate</code>	Sets the baud rate.
<code>vdvrOpCodeSetSettingsFlags</code>	Sets the data transmission options. The bit flags are described in <a href="#">Serial Settings Constants</a> .
<code>vdrvOpCodeSetCtsTimeout</code>	Hardware handshake timeout.
<code>vdvrOpCodeClearErr</code>	Clears the hardware error state.
<code>vdvrOpCodeSetSleepMode</code>	Puts the port in sleep mode (not typically used for virtual drivers).
<code>vdvrOpCodeSetWakeupMode</code>	Wakes up the port from sleep mode (not typically used for virtual drivers).
<code>vdvrOpCodeFIFOCount</code>	Returns the number of bytes currently in the FIFO (or best estimate).
<code>vdvrOpCodeStartBreak</code>	Sends a break character or enables the sending of break characters.
<code>vdvrOpCodeStopBreak</code>	Stops sending break characters.
<code>vdvrOpCodeStartLoopback</code>	Starts loopback mode (not typically used for virtual drivers).
<code>vdvrOpCodeStopLoopback</code>	Stops loopback mode (not typically used for virtual drivers).
<code>vdrvOpCodeFlushTxFIFO</code>	Flushes the contents of the transmit FIFO.
<code>vdrvOpCodeFlushRxFIFO</code>	Flushes the contents of the receive FIFO.

<code>vdrvOpCodeSendBufferedData</code>	Notifies virtual device to send any buffered data it has not emptied from its internal buffers.
<code>vdrvOpCodeRcvCheckIdle</code>	Called periodically to allow the virtual device time to check if there is data to be received. Because virtual devices execute in the same thread as applications, they can be prevented from handling notifications of received data.
<code>vdrvOpCodeEmuSetBlockingHook</code>	Special op code for the Simulator.
<code>vdrvOpCodeGetOptTransmitSize</code>	Returns the optimum buffer size for sending data or returns 0 to specify any buffer size is acceptable.
<code>vdrvOpCodeGetMaxRcvBlockSize</code>	Returns the maximum receive block size that the Serial Manager should request from the virtual device. Can be used to implement flow control.
<code>vdrvOpCodeNotifyBytesReadFromQ</code>	Tells the virtual device that some number of bytes have been read from the receive queue by the client application. Can be used to implement flow control.
<code>vdrvOpCodeSetDTRAsserted</code>	Asserts or de-asserts the DTR signal.
<code>vdrvOpCodeGetDTRAsserted</code>	Gets the status of the DTR signal.
<code>vdrvOpCodeWaitForConfiguration</code>	Waits for USB enumeration to complete. Called from the send and receive functions of the Serial Manager. The driver should have a timeout for how long it waits for enumeration to complete. The driver should return with no error if enumeration has already occurred or has occurred within the driver's timeout. If the enumeration has not occurred within the driver's timeout, the driver should return <code>serErrTimeOut</code> .

## Virtual Drivers

### *VdrvCtlOpCodeEnum*

---

<code>vdrvOpCodeGetUSBDeviceDescriptor</code>	Retrieves the device descriptor of a USB driver. Used to gather information about the device's capabilities. Implementation of this op code is optional. If the driver chooses to implement this op code, then the driver should return a pointer to the device descriptor. A driver that chooses not to implement this op code should return <code>serErrNotSupported</code> .
<code>vdrvOpCodeGetUSBConfigDescriptor</code>	Retrieves the configuration descriptor of a USB driver. Used to gather information about the device's capabilities. Implementation of this op code is optional. If the driver chooses to implement this op code, then the driver should return a pointer to the device descriptor. A driver that chooses not to implement this op code should return <code>serErrNotSupported</code> .
<code>vdrvOpCodeEnableIRDA</code>	Enable the IrDA mode and power up the IR line drivers.
<code>vdrvOpCodeDisableIRDA</code>	Disable the IrDA mode and disable the IR line drivers.
<code>vdrvOpCodeEnableUART</code>	Powers up the UART and the line drivers.
<code>vdrvOpCodeDisableUART</code>	Powers down the UART and the line drivers.
<code>vdrvOpCodeRxEnable</code>	Enables the receive FIFO, enables UART interrupts, and does whatever else is necessary to allow the UART to receive data.
<code>vdrvOpCodeRxDisable</code>	Disables the receive FIFO and UART interrupts and does whatever is needed to prevent the UART from receiving data.
<code>vdrvOpCodeLineEnable</code>	Enables the main serial line driver for the UART.

<code>vdrvOpCodeEnableUARTInterrupts</code>	Enables the appropriate UART receive interrupts.
<code>vdrvOpCodeDisableUARTInterrupts</code>	Disables all UART interrupts.
<code>vdrvOpCodeSetReceiveQueue</code>	This op code is used by the Serial Manager to set the driver's receive queue. This control code is called when a driver that has previously been opened as a background port is opened as a fully open bidirectional port.
<code>vdrvOpCodeSaveState</code>	Invoked when this port is yielded. This is a hook for the driver to save any current state.
<code>vdrvOpCodeRestoreState</code>	Invoked when the foreground port is closed and this port can become the foreground port.
<code>vdrvOpCodeSetYieldPortCallback</code>	Set the function to be called if the Serial Manager attempts to open another port when this one is open. This op code is for system use only.
<code>vdrvOpCodeSetYieldPortRefCon</code>	Data to pass to the yield port callback function. System use only.
<code>vdrvOpCodeUserDef</code>	User defined function invoked through <a href="#">SrmControl()</a> .
<code>vdrvOpCodeSystem</code>	Reserves op codes between 0x7000 and 0x8000 for system use.
<code>vdrvOpCodeCustom</code>	Reserves op codes greater than 0x8000 for driver-specific use.

**Compatibility** The op codes starting at `vdrvOpCodeWaitForConfiguration` are defined only if [New Serial Manager Feature Set Version 2](#) is present. The op codes for yieldable ports and custom operations are defined only if both [4.0 New Feature Set](#) is present as well.

## Driver Constants

### Driver Version Constants

The driver version constants specify which version of the driver API is implemented by this driver. The [DrvEntryPointProcPtr\(\)](#) function passes this value back to the Serial Manager in the `drvVersion` field of the [DrvInfoType](#) function.

Constant	Value	Description
<code>kDrvVersion</code>	4	The latest version of the API.
<code>kDrvVersion3</code>	3	The version of the driver API that corresponds to <a href="#">New Serial Manager Feature Set Version 1</a> (which ships with roughly Palm OS® 3.3 up to Palm OS 4.0).
<code>kDrvVersion4</code>	4	The version of the driver API that corresponds to <a href="#">New Serial Manager Feature Set Version 2</a> (which ships with roughly Palm OS 4.0 and higher).

### Port Feature Constants

The port feature constants are flags that describe serial hardware capabilities.

Constant	Value	Description
<code>portPhysicalPort</code>	0x00000001	Should be set for a physical port, unset for a virtual port.
<code>portBkgndModeSupported</code>	0x00000002	Denotes that this port can be used for background ports. This flag is only applicable to virtual drivers. Background mode support is implied on physical drivers.

Constant	Value	Description
portRS232Capable	0x00000004	Set if this hardware has an RS-232 port.
portIRDACapable	0x00000008	Set if this hardware has an IR port and supports IrDA mode.
portCradlePort	0x00000010	Set if this hardware controls the cradle port.
portExternalPort	0x00000020	Set if this hardware port is external or on a memory card.
portModemPort	0x00000040	Set if this hardware communicates with a modem.
portCncMgrVisible	0x00000080	Set if this serial port's name is to be displayed in the Connection panel.
portConsolePort	0x00000100	Denotes this hardware controls the console port.
portUSBCapable	0x00000200	Set if this hardware has a USB port.
portPrivateUse	0x00001000	Set if this driver is for special software and not general applications.

**Compatibility**    USB support is only available if [New Serial Manager Feature Set Version 2](#) is present.

## Virtual Driver-Defined Functions

The functions in this section must be defined by your virtual driver.

## DrvEntryPointProcPtr Function

<b>Purpose</b>	Entry point for the virtual driver.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<pre>Err (*DrvEntryPointProcPtr)     (DrvEntryOpCodeEnum opCode, void *uartData)</pre>
<b>Parameters</b>	<p>→ <i>opCode</i> Entry function code.</p> <p>↔ <i>uartData</i> Pointer to data specific to opCode.</p>
<b>Returns</b>	<p><code>errNone</code> No error.</p> <p>-1 The op code is invalid or the hardware could not be found.</p>
<b>Comments</b>	<p>This function's purpose is based on the value of the <code>opCode</code> parameter. The three possible codes are <code>drvEntryGetUartFeatures</code>, <code>drvEntryGetDrvrFuncs</code>, and <code>drvEntryGetUartFtrsNEntries</code>.</p> <p><code>DrvEntryPoint</code> is called with the <code>drvEntryGetUartFeatures</code> code when the Serial Manager is installed into the system at boot time and is looking for all installed drivers. When this op code is set, the <code>uartData</code> pointer points to a <a href="#">DrvrInfoType</a> structure. This function does not allocate the structure, it just fills in the fields with information.</p> <p>This function should check to make sure the associated serial device can operate under the current OS and system settings. If the hardware cannot be found, the function should leave the <code>DrvrInfoType</code> struct untouched and return a -1 error.</p> <p>The driver needs to supply a string that describes the port it manages. This string is displayed to the user in the Connection panel and is returned by the <a href="#">SrmGetDeviceInfo()</a> function. To set this string, copy it into the <code>portDesc</code> field of the <code>DrvrInfoType</code> structure. Alternatively, you can supply this string in a driver resource of type 'tSTR' and id <code>kPortDescStrID</code>.</p> <p>If the <code>DrvrInfoType</code> structure has a positive value in the <code>multipleEnumerations</code> field upon return, the Serial Manager</p>

defines one port for each entry in the driver table. The `DrvEntryPoint` function is called again, this time with the `drvEntryGetUartFtrsNEntries` code. The `uartData` pointer points to a new `DrvInfoType` structure whose `multipleEnumerations` field indicates which port is to be defined. The function should supply all information specific to this port.

`DrvEntryPoint` is called with the `drvEntryGetDrvFuncs` code when a virtual port is opened. The `uartData` pointer points to a `VdrvAPIType` structure and `DrvEntryPoint` must fill in the fields of this structure with appropriate function pointers.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

The `drvEntryGetUartFtrsNEntries` is only supported if [New Serial Manager Feature Set Version 2](#) is present. This function is fully backwards compatible. Passing 0 for the `multipleEnumerations` field defines a single port for the driver.

## VdrvCloseProcPtr Function

<b>Purpose</b>	Handles all activities needed to close the virtual device.
<b>Declared In</b>	<code>SerialDrv.h</code>
<b>Prototype</b>	<code>Err (*VdrvCloseProcPtr) (VdrvDataPtr drvData)</code>
<b>Parameters</b>	→ <code>drvData</code> Pointer to the driver's private global area.
<b>Returns</b>	<code>errNone</code> No error.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## **VdrvControlProcPtr Function**

<b>Purpose</b>	Extends the <code>SrmControl</code> function to the level of the virtual device.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<pre>Err (*VdrvControlProcPtr) (VdrvDataPtr drvvrData,     VdrvCtlOpCodeEnum controlCode,     void *controlData, UInt16 *controlDataLen)</pre>
<b>Parameters</b>	<p>→ <i>drvvrData</i> Pointer to the driver's private global area.</p> <p>→ <i>controlCode</i> Control function op code. One of the op codes listed in the <a href="#">VdrvCtlOpCodeEnum</a> type.</p> <p>↔ <i>controlData</i> Pointer to data for the specified control function.</p> <p>↔ <i>controlDataLen</i> Pointer to length of control data being passed in or out.</p>
<b>Returns</b>	<p><code>errNone</code> No error.</p> <p><code>serErrNotSupported</code> controlCode not supported.</p> <p><code>serErrBadParam</code> controlData or controlDataLen is bad.</p>
<b>Comments</b>	<p>This function should support the op codes listed in the <a href="#">VdrvCtlOpCodeEnum</a> type. If this function does not support an op code, it must return the <code>serErrNotSupported</code> error code for that op code.</p> <p><a href="#">Table 64.1</a> shows what is passed for the <code>controlData</code> and <code>controlDataLen</code> parameters for each of the control codes that use them. Control codes not listed do not use these parameters.</p>

**Table 64.1 VDrvControlProcPtr Parameters**

vdvrOpCodeSetBaudRate	<p>→ <i>controlData</i> = Pointer to <i>Int32</i> (baud rate),</p> <p>→ <i>controlDataLen</i> = Pointer to <i>sizeof(Int32)</i>.</p>
vdvrOpCodeSetSettingsFlags	<p>→ <i>controlData</i> = Pointer to <i>UInt32</i> (bitfield; see <a href="#">Serial Settings Constants</a>)</p> <p>→ <i>controlDataLen</i> = Pointer to <i>sizeof(UInt32)</i></p>
vdvrOpCodeFIFOCount	<p>→ <i>controlData</i> = Pointer to <i>Int16</i>, which contains the number of bytes in the FIFO.</p> <p>→ <i>controlDataLen</i> = Pointer to <i>sizeof(Int16)</i>.</p>
vdrvOpCodeGetOptTransmitSize	<p>← <i>controlData</i> = Pointer to <i>Int32</i> (buffer size),</p> <p>← <i>controlDataLen</i> = Pointer to <i>sizeof(Int32)</i>.</p> <p>Return the optimum buffer size for sending data, or 0 to specify any buffer size is acceptable.</p>
vdrvOpCodeGetMaxRcvBlockSize	<p>← <i>controlData</i> = Pointer to <i>Int32</i> (block size),</p> <p>← <i>controlDataLen</i> = Pointer to <i>sizeof(Int32)</i>.</p> <p>Return the maximum block size that the Serial Manager should request from the virtual device.</p>
vdrvOpCodeNotifyBytesReadFromQ	<p>→ <i>controlData</i> = Pointer to <i>Int32</i> (number of bytes read),</p> <p>→ <i>controlDataLen</i> = Pointer to <i>sizeof(Int32)</i>.</p>

## Virtual Drivers

*VdrvControlCustomProcPtr*

---

**Table 64.1 VDrvControlProcPtr Parameters (*continued*)**

vdrvOpCodeSetDTRAsserted	<i>→ controlData = Pointer to Boolean indicating whether to enable or disable DTR.</i> <i>→ controlDataLen = Pointer to sizeof(Boolean)</i>
vdrvOpCodeGetDTRAsserted	<i>← controlData = Pointer to Boolean indicating whether DTR is enabled.</i> <i>← controlDataLen = Pointer to sizeof(Boolean)</i>
vdvrOpCodeUserDef	<i>↔ controlData = Pointer from <a href="#">SrmControl()</a> (user-defined data),</i> <i>↔ controlDataLen = Pointer to sizeof(Int32).</i>

---

**Compatibility**    Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

### VdrvControlCustomProcPtr Function

**Purpose**            Extends the SrmCustomControl function to the level of the virtual device.

**Declared In**      SerialDrvr.h

**Prototype**        Err (\*VdrvControlCustomProcPtr)  
                      (VdrvDataPtr drvData, UInt16 opCode,  
                      UInt32 creator, void \*controlData,  
                      void \*controlDataLenP)

**Parameters**        *→ drvData*  
                      Pointer to the driver's private global area.  
  
                      *→ controlCode*  
                      Control function op code.

	→ <i>creator</i>	Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.
	↔ <i>controlData</i>	Pointer to data for the specified control function.
	↔ <i>controlDataLen</i>	Pointer to length of control data being passed in or out.
<b>Returns</b>	<i>errNone</i>	No error.
	<i>serErrNotSupported</i>	controlCode not supported.
	<i>serErrBadParam</i>	controlData or controlDataLen is bad.
<b>Comments</b>	This function is a mechanism for a virtual driver to create control codes specific to that driver, allowing for the support of new technologies that have interfaces through the Serial Manager.	
<b>Compatibility</b>	Implemented only if both <a href="#">New Serial Manager Feature Set Version 2</a> and <a href="#">4.0 New Feature Set</a> are present.	

## VdrvOpenProcPtr Function

<b>Purpose</b>	Initializes the virtual device to begin communication.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<code>Err (*VdrvOpenProcPtr) (VdrvDataPtr *drvData, UInt32 baudRate, DrvrHWRCvQPtr rcvQP)</code>
<b>Parameters</b>	<p>↔ <i>drvData</i>            Pointer to a pointer to the driver's private global area (allocated by this function). A pointer to this private global area is passed to the other virtual driver functions.</p> <p>→ <i>baudRate</i>            Initial baud rate setting.</p> <p>→ <i>rcvQP</i>            Pointer to the driver's receive queue buffer structure. For details on the fields, see <a href="#">DrvrRcvQType</a>.</p>

## Virtual Drivers

### *VdrvOpenProcV4Ptr*

---

<b>Returns</b>	<code>errNone</code> No error.
<b>Comments</b>	This function must allocate and initialize any global variables (and pass back a pointer to a pointer to them in <code>drvDataP</code> ), do any set-up necessary for communicating with other software, and save the <code>rcvQP</code> pointer since it will need the functions and pointers to structures enclosed within to be able to save received data into the Serial Manager's receive queue.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## VdrvOpenProcV4Ptr Function

<b>Purpose</b>	Initializes the virtual device to begin communication.
<b>Declared In</b>	<code>SerialDrv.h</code>
<b>Prototype</b>	<code>Err (*VdrvOpenProcV4Ptr) (VdrvDataPtr *drvData, VdrvConfigPtr configP, DrvrHWRCvQPtr rcvQP)</code>
<b>Parameters</b>	<p><math>\leftrightarrow</math> <i>drvData</i> Pointer to a pointer to the driver's private global area (allocated by this function). A pointer to this private global area is passed to the other virtual driver functions.</p> <p><math>\rightarrow</math> <i>configP</i> Pointer to the configuration structure specifying the port's properties. See <a href="#">VdrvConfigType</a>.</p> <p><math>\rightarrow</math> <i>rcvQP</i> Pointer to the driver's receive queue buffer structure. For details on the fields, see <a href="#">DrvrRcvQType</a>.</p>
<b>Returns</b>	<code>errNone</code> No error.
<b>Comments</b>	This function must allocate and initialize any global variables (and pass back a pointer to a pointer to them in <code>drvDataP</code> ), do any set-up necessary for communicating with other software, and save the <code>rcvQP</code> pointer since it will need the functions and pointers to structures enclosed within to be able to save received data into the Serial Manager's receive queue.

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## VdrvStatusProcPtr Function

**Purpose** Returns virtual device status.

**Declared In** `SerialDrvr.h`

**Prototype** `UInt16 (*VDrvStatusProcPtr) (VdrvDataPtr  
drvData)`

**Parameters**  $\rightarrow$  *drvData*  
Pointer to the driver's private global area.

**Returns** An unsigned long bitfield denoting the status of the virtual device, but only if the virtual device is emulating hardware. The individual bit flags are described in the [DrvStatusEnum](#) type.

**Comments** Generally, status is returned only to the client application using the virtual device. The Serial Manager does not use status information from virtual devices.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## VdrvWriteProcPtr Function

**Purpose** Writes a block of bytes.

**Declared In** `SerialDrvr.h`

**Prototype** `UInt32 (*VdrvWriteProcPtr)  
(VdrvDataPtr drvDataP, void *bufP,  
UInt32 size, Err *errP)`

**Parameters**  $\rightarrow$  *drvDataP*  
Pointer to the driver's private global area.

$\rightarrow$  *bufP*  
Pointer to buffer containing the data to be written to the virtual device.

$\rightarrow$  *size*  
Number of bytes in the buffer *bufP*.

## Virtual Drivers

### Serial Manager Queue Functions

---

← *errP*

Pointer to an error code resulting from the operation. Zero is returned if there is no error.

**Returns** Returns the actual number of bytes written.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## Serial Manager Queue Functions

The functions in this section are supplied by the Serial Manager to the virtual driver through the [DrvRcvQType](#) passed to the [VdrvOpenProcPtr\(\)](#) function.

### GetSizeProcPtr Function

**Purpose** Returns the total size of the Serial Manager's receive queue.

**Declared In** `SerialDrv.h`

**Prototype** `typedef UInt32 (*GetSizeProcPtr) (void *theQ)`

**Parameters** → *theQ*  
Pointer to the receive queue.

**Returns** Size in bytes of the Serial Manager's receive queue.

**Comments** This function is useful for implementing flow control.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

### GetSpaceProcPtr Function

**Purpose** Returns the available space in the Serial Manager's receive queue.

**Declared In** `SerialDrv.h`

**Prototype** `typedef UInt32 (*GetSpaceProcPtr) (void *theQ)`

**Parameters** → *theQ*  
Pointer to the receive queue.

<b>Returns</b>	Size in bytes of the available space in the Serial Manager's receive queue.
<b>Comments</b>	This function is useful for implementing flow control.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## SignalCheckPtr Function

<b>Purpose</b>	Check the queue to see if the semaphore needs to be signalled.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<pre>typedef void (*SignalCheckPtr) (void *theQ,                                 UInt16 lineErrsP)</pre>
<b>Parameters</b>	<p>→ <i>theQ</i> Pointer to the receive queue.</p> <p>→ <i>lineErrsP</i> Any serial line errors received should be reported here.</p>
<b>Returns</b>	Returns nothing.
<b>Comments</b>	This function signals that there is data to be received without writing anything to the receive queue. The <a href="#">WriteByteProcPtr()</a> and <a href="#">WriteBlockProcPtr()</a> functions also signal that there is data to be received after they have written the data to the queue.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 2</a> is present.

## WriteBlockProcPtr Function

<b>Purpose</b>	Writes a block of bytes to the Serial Manager's receive queue.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<pre>typedef Err (*WriteBlockProcPtr) (void *theQ,                                    UInt8 *bufP, UInt16 size, UInt16 lineErrs)</pre>
<b>Parameters</b>	<p>→ <i>theQ</i> Pointer to the receive queue.</p> <p>→ <i>bufP</i> Pointer to the buffer holding bytes to be written.</p>

## Virtual Drivers

### *WriteByteProcPtr*

---

	<i>→ size</i> Size of bufP.
	<i>→ lineErrs</i> Any serial line errors received should be reported here.
<b>Returns</b>	<code>errNone</code> No error.  <code>serErrLineErr</code> There was a software overrun line error.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## WriteByteProcPtr Function

<b>Purpose</b>	Writes one byte to the Serial Manager's receive queue.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<code>typedef Err (*WriteByteProcPtr) (void *theQ, UInt8 theByte, UInt16 lineErrs)</code>
<b>Parameters</b>	<i>→ theQ</i> Pointer to the receive queue.  <i>→ theByte</i> The byte to be written to the queue.  <i>→ lineErrs</i> Any serial line errors received should be reported here.
<b>Returns</b>	<code>errNone</code> No error.  <code>serErrLineErr</code> There was a software overrun line error.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

# Serial Manager

---

This chapter provides reference material for the Serial Manager API:

- [Serial Manager Data Structures](#)
- [Serial Manager Constants](#)
- [Serial Manager Functions](#)
- [Serial Manager Application-Defined Functions](#)

The header file `SerialMgr.h` declares the Serial Manager API. The file `SystemResources.h` defines some serial port constants. For more information on the Serial Manager, see the chapter “[Serial Communication](#)” on page 89 of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Serial Manager Data Structures

### DeviceInfoType Struct

**Purpose** The `DeviceInfoType` structure defines information about a serial device. This structure is returned by the [SrmGetDeviceInfo\(\)](#) function.

**Prototype**

```
typedef struct DeviceInfoType {
    UInt32 serDevCreator;
    UInt32 serDevFtrInfo;
    UInt32 serDevMaxBaudRate;
    UInt32 serDevHandshakeBaud;
    Char *serDevPortInfoStr;
    UInt8 reserved[8];
} DeviceInfoType;
typedef DeviceInfoType *DeviceInfoPtr;
```

## Serial Manager

### *SrmCtlEnum*

---

#### Value Descriptions

<code>serDevCreator</code>	Four-character creator ID for serial driver.
<code>serDevFtrInfo</code>	Flags defining features of this serial hardware. See <a href="#">Serial Capabilities Constants</a> for a description of these flags.
<code>serDevMaxBaudRate</code>	Maximum baud rate for this device.
<code>serDevHandshakeBaud</code>	Hardware handshaking is recommended for baud rates over this rate.
<code>serDevPortInfoStr</code>	Description of serial hardware device or virtual device.

#### SrmCtlEnum Enum

**Purpose** The `SrmCtlEnum` enumerated type specifies a serial control operation. Specify one of these enumerated types for the `op` parameter to the [SrmControl\(\)](#) call.

**Prototype**

```
typedef enum SrmCtlEnum {  
    srmCtlFirstReserved = 0,  
    srmCtlSetBaudRate,  
    srmCtlGetBaudRate,  
    srmCtlSetFlags,  
    srmCtlGetFlags,  
    srmCtlSetCtsTimeout,  
    srmCtlGetCtsTimeout,  
    srmCtlStartBreak,  
    srmCtlStopBreak,  
    srmCtlStartLocalLoopback,  
    srmCtlStopLocalLoopback,  
    srmCtlIrDAEnable,  
    srmCtlIrDADisable,  
    srmCtlRxEnable,  
    srmCtlRxDisable,  
    srmCtlEmuSetBlockingHook,  
}
```

```

    srmCtlUserDef,
    srmCtlGetOptimalTransmitSize,
    srmCtlSetDTRAsserted,
    srmCtlGetDTRAsserted,
    srmCtlSetYieldPortCallback,
    srmCtlSetYieldPortRefCon,
    srmCtlSystemReserved = 0x7000
    srmCtlCustom = 0x8000,
    srmCtlLAST
} SrmCtlEnum;

```

### Value Descriptions

<code>srmCtlSetBaudRate</code>	Sets the current baud rate for the serial hardware.
<code>srmCtlGetBaudRate</code>	Gets the current baud rate for the serial hardware.
<code>srmCtlSetFlags</code>	Sets the current flag settings for the serial hardware. Specify flags from the set described in <a href="#">Serial Settings Constants</a> .
<code>srmCtlGetFlags</code>	Gets the current flag settings for the serial hardware.
<code>srmCtlSetCtsTimeout</code>	Sets the current CTS timeout value for hardware handshaking.
<code>srmCtlGetCtsTimeout</code>	Gets the current CTS timeout value for hardware handshaking.
<code>srmCtlStartBreak</code>	Turn RS-232 break signal on. Caller is responsible for turning this signal on and off and insuring it is on long enough to generate a viable break.
<code>srmCtlStopBreak</code>	Turn RS-232 break signal off.
<code>srmCtlStartLocalLoopback</code>	Start local loopback test.
<code>srmCtlStopLocalLoopback</code>	Stop local loopback test.

## Serial Manager

### *SrmCtlEnum*

---

<code>srmCtlIrDAEnable</code>	Enable IrDA connection on this serial port.  <b>NOTE:</b> You cannot enable an IrDA connection on a VZ processor.
<code>srmCtlIrDADisable</code>	Disable IrDA connection on this serial port.
<code>srmCtlRxEnable</code>	Enable receiver (for IrDA).
<code>srmCtlRxDisable</code>	Disable receiver (for IrDA).
<code>srmCtlEmuSetBlockingHook</code>	Set a blocking hook routine for emulation mode only. Not supported on the actual device.
<code>srmCtlUserDef</code>	<p>This is a user-defined function that third-party hardware developers can use to set or retrieve hardware-specific information from the serial driver. This op code invokes the driver's corresponding control function with its user-defined op code and the parameters are passed directly through to the serial driver. A serial driver that does not handle this function returns a <code>serErrBadParam</code> error.</p> <p>The <code>srmCtlUserDef</code> op code is superseded by defining a custom op code if <a href="#">New Serial Manager Feature Set Version 2</a> is present.</p>
<code>srmCtlGetOptimalTransmitSize</code>	Ask the port for the most efficient buffer size for transmitting data packets. This op code returns an error (buffering not necessary), 0 (buffering requested, but application can choose buffer size), or a number greater than 0 (recommended buffer size).
<code>srmCtlSetDTRAsserted</code>	Enabled or disable the DTR signal. This is not supported by all hardware.
<code>srmCtlGetDTRAsserted</code>	Ask the port whether the DTR signal is enabled or disabled.

<code>srmCtlSetYieldPortCallback</code>	Set the function to be called if the Serial Manager attempts to open another port when this one is open. This op code is for system use only.
<code>srmCtlSetYieldPortRefCon</code>	Data to pass to the yield port callback function. System use only.
<code>srmCtlSystemReserved</code>	Reserves op codes between 0x7000 and 0x8000 for system use.
<code>srmCtlCustom</code>	Reserves op codes greater than 0x8000 for driver-specific use.

**Compatibility** Custom control op codes are only supported if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## SrmOpenConfigType Struct

**Purpose** The `SrmOpenConfigType` structure specifies parameters for opening a serial port. This structure is passed as a parameter to [SrmExtOpen\(\)](#).

**Prototype**

```
typedef struct SrmOpenConfigType {
    UInt32 baud;
    UInt32 function;
    MemPtr drvvrDataP;
    UInt16 drvvrDataSize;
    UInt32 sysReserved1;
    UInt32 sysReserved2;
} SrmOpenConfigType;
```

**Field Descriptions**

<code>baud</code>	Baud rate at which to open the connection. Serial drivers that do not require baud rates ignore this field.
<code>function</code>	<p>The reason why the port was opened. Specify the creator ID of the application that is opening the port or one of the following values:</p> <p><code>serFncUndefined</code> Undefined function. This is the default value for this field.</p> <p><code>serFncPPPSession</code> The connection is to be used for the PPP interface.</p> <p><code>serFncSLIPSession</code> The connection is to be used for the SLIP session.</p> <p><code>serFncDebugger</code> The connection is to be used for a debugging session.</p> <p><code>serFncHotSync</code> The connection is to be used for a HotSync operation.</p> <p><code>serFncConsole</code> The connection is to the debugging console.</p> <p><code>serFncTelephony</code> The connection is to the telephony library.</p> <p>The function field is used by protocols such as USB and Bluetooth that perform different setup tasks based on which type of application is using them. RS-232 drivers ignore this parameter.</p>
<code>drvDataP</code>	Pointer to a driver-specific data block.
<code>drvDataSize</code>	The size of the data block pointed to by <code>drvDataP</code> .

sysReserved1    Reserved for future use.

sysReserved2    Reserved for future use.

**Compatibility**    This structure is only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## Serial Manager Constants

### Port Constants

When you specify the port to open in the [SrmOpen\(\)](#), [SrmOpenBackground\(\)](#), [SrmExtOpen\(\)](#), or [SrmExtOpenBackground\(\)](#) call, you can use either a logical port constant, physical port constant, or a virtual port constant, but it is highly recommended that you use a logical port constant wherever possible.

#### Logical Serial Port Constants

These constants specify the logical port names.

Constant	Value	Description
serPortLocalHotSync	0x8000	The physical HotSync port. The Serial Manager automatically detects whether this port is USB or RS-232.
serPortCradlePort	0x8000	Cradle port. The Serial Manager automatically detects whether this port is USB or RS-232. Most applications should specify this as the port.
serPortIrPort	0x8001	The IR port. This is a raw IrDA port with no protocol support.
serPortConsolePort	0x8002	The debug console port, either USB or RS-232. USB is preferred where both are available.

## Serial Manager

### Port Constants

---

Constant	Value	Description
<code>serPortCradleRS232Port</code>	0x8003	Port for the RS-232 cradle. Specify this port if you want to ensure that your application uses RS-232 communications only.
<code>serPortCradleUSBPort</code>	0x8004	Port for the USB cradle. Specify this port if you want to ensure that your application uses USB communications only.

**Compatibility** USB ports are only supported if [New Serial Manager Feature Set Version 2](#) is present.

#### Physical Serial Port Constants

The physical port constants specify 4-character constants that reference the physical hardware of the device. Doing so is **not** recommended because the hardware they reference may not exist on a particular device.

Physical port	Value	Description
<code>sysFileCUart328</code>	'u328'	Cradle port using the 68328 UART. This port can be switched between RS232 and IrDA mode using the <a href="#">SrmControl()</a> call.
<code>sysFileCUart328EZ</code>	'u8EZ'	Cradle port using the 68328EZ UART. This port can also be switched between RS232 and IrDA mode.
<code>sysFileCUart650</code>	'u650'	Specifies the IR port on the upgrade card for Palm Personal or Palm Professional devices. This gives you a raw IR port like calling <code>SrmControl</code> does, but it only exists on devices that have the upgrade card.

#### Virtual Serial Port Constants

The virtual port constants specify 4-character constants that identify virtual ports, simulating a hardware interface. Virtual ports are not tied to specific hardware.

Physical port	Value	Description
<code>sysFileCVirtIrComm</code>	'ircm'	A virtual serial cable over an IrDA link using the IRComm protocol. It can only be used to talk to another IRComm device.
<code>sysFileCVirtRfComm</code>	'rfcm'	RFCOMM (Bluetooth) virtual port plug-in.
<code>sysFileCBtConnectPanelHelper</code>	'btcp'	Bluetooth Connection Panel helper application.

**Compatibility** All virtual port constants other than `sysFileCVirtIrComm` are only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## Serial Capabilities Constants

The serial capabilities constant flags describe serial hardware capabilities. These flags are set in the `serDevFtrInfo` field of the [DeviceInfoType](#) structure.

Constant	Value	Description
<code>serDevCradlePort</code>	0x00000001	Serial hardware controls RS-232 serial from cradle connector of Palm device.
<code>serDevRS232Serial</code>	0x00000002	Serial hardware has RS-232 line drivers.
<code>serDevIRDACapable</code>	0x00000004	Serial hardware has IR line drivers and generates IrDA mode serial signals.
<code>serDevModemPort</code>	0x00000008	Serial hardware drives modem connection.

## Serial Manager

### Serial Settings Constants

---

Constant	Value	Description
serDevCncMgrVisible	0x00000010	Serial device port name string is to be displayed in the Connection panel.
serDevConsolePort	0x00000020	Serial device is the default console port.
serDevUSBCapable	0x00000040	Serial hardware controls USB serial from cradle connector of Palm device.

---

**Compatibility** USB ports are only supported if [New Serial Manager Feature Set Version 2](#) is present.

## Serial Settings Constants

The serial settings constants identify bit flags that correspond to various serial hardware settings. Use [srmControl\(\)](#) with the opcode `srmCtlSetFlags` to control which settings are used.

Constant	Value	Description
srmSettingsFlagStopBitsM	0x00000001	Mask for stop bits field
srmSettingsFlagStopBits1	0x00000000	1 stop bit (default)
srmSettingsFlagStopBits2	0x00000001	2 stop bits
srmSettingsFlagParityOnM	0x00000002	Mask for parity on
srmSettingsFlagParityEvenM	0x00000004	Mask for parity even
srmSettingsFlagXonXoffM	0x00000008	Mask for Xon/Xoff flow control (not implemented)
srmSettingsFlagRTSAutoM	0x00000010	Mask for RTS receive flow control. This is the default.
srmSettingsFlagCTSAutoM	0x00000020	Mask for CTS transmit flow control

---

Constant	Value	Description
<code>srmSettingsFlagBitsPerCharM</code>	<code>0x000000C0</code>	Mask for bits per character
<code>srmSettingsFlagBitsPerChar5</code>	<code>0x00000000</code>	5 bits per character
<code>srmSettingsFlagBitsPerChar6</code>	<code>0x00000040</code>	6 bits per character
<code>srmSettingsFlagBitsPerChar7</code>	<code>0x00000080</code>	7 bits per character
<code>srmSettingsFlagBitsPerChar8</code>	<code>0x000000C0</code>	8 bits per character (default)
<code>srmSettingsFlagFlowControlIn</code>	<code>0x00000100</code>	Protect the receive buffer from software overruns. When this flag and <code>srmSettingsFlagRTSAutoM</code> are set, which is the default case, it causes the Serial Manager to assert RTS to prevent the transmitting device from continuing to send data when the receive buffer is full. Once the application receives data from the buffer, RTS is de-asserted to allow data reception to resume.

## Serial Manager

### Status Constants

---

Constant	Value	Description
		Note that this feature effectively prevents software overrun line errors but may also cause CTS timeouts on the transmitting device if the RTS line is asserted longer than the defined CTS timeout value.
<code>srmSettingsFlagRTSInactive</code>	<code>0x00000200</code>	If this flag is set and <code>srmSettingsFlagRTSAutoM</code> is not set, RTS is held in the inactive (flow off) state forever.

---

## Status Constants

The status constants identify bit flags that correspond to the status of serial signals. They can be returned by the [SrmGetStatus\(\)](#) function.

Constant	Value	Description
<code>srmStatusCtsOn</code>	<code>0x00000001</code>	CTS line is active.
<code>srmStatusRtsOn</code>	<code>0x00000002</code>	RTS line is active.
<code>srmStatusDsrOn</code>	<code>0x00000004</code>	DSR line is active.
<code>srmStatusBreakSigOn</code>	<code>0x00000008</code>	Break signal is active.

---

## Line Error Constants

The line error constants identify bit flags that correspond to the line errors that may occur on the port. They can be returned by the [SrmGetStatus\(\)](#) function.

Constant	Value	Description
serLineErrorParity	0x0001	Parity error
serLineErrorHWOverrun	0x0002	Hardware overrun
serLineErrorFraming	0x0004	Framing error
serLineErrorBreak	0x0008	Break signal asserted
serLineErrorHShake	0x0010	Line handshake error
serLineErrorSWOverrun	0x0020	Software overrun
serLineErrorCarrierLost	0x0040	Carrier detect signal dropped

## Serial Manager Functions

### SrmClearErr Function

<b>Purpose</b>	Clears the port of any line errors.
<b>Declared In</b>	SerialMgr.h
<b>Prototype</b>	Err SrmClearErr (UInt16 portId)
<b>Parameters</b>	→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a> .
<b>Returns</b>	This function returns the following error codes: errNone No error. serErrNotSupported The port is not the foreground port.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## SrmClose Function

<b>Purpose</b>	Closes a serial port and makes it available to other applications, regardless of whether the port is a foreground or background port.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmClose (UInt16 portId)</code>
<b>Parameters</b>	<code>→ portId</code> Port ID for port to be closed.
<b>Returns</b>	This function returns the following error codes:  <code>errNone</code> No error.  <code>serErrBadPort</code> This port doesn't exist.  <code>serErrNotOpen</code> The serial port is not open.  <code>serErrNoDevicesAvail</code> No serial devices could be found.
<b>Comments</b>	<p>If a foreground port is being closed and a background port exists, the background will have access to the port as long as another foreground port is not opened.</p> <p>If a foreground port is being closed and a yielded port exists, the yielded port will have access to the port as long as it does not yield to the opening of another foreground port. If there are both a yielded port and a background port for the foreground port being closed, the yielded port takes precedence over the background port.</p>
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmOpen()</a> , <a href="#">SrmOpenBackground()</a>

## SrmControl Function

<b>Purpose</b>	Performs a serial control function.
<b>Declared In</b>	SerialMgr.h
<b>Prototype</b>	Err SrmControl (UInt16 portId, UInt16 op, void *valueP, UInt16 *valueLenP)
<b>Parameters</b>	<p>→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>→ <i>op</i> Control operation to perform. Specify one of the <a href="#">SrmCtlEnum</a> enumerated types.</p> <p>↔ <i>valueP</i> Pointer to a value to use for the operation. See Comments for details.</p> <p>↔ <i>valueLenP</i> Pointer to the size of *valueP. See Comments for details.</p>
<b>Returns</b>	<p>This function returns the following error codes:</p> <p><code>errNone</code> No error.</p> <p><code>serErrBadParam</code> An invalid op code was specified.</p> <p><code>serErrBadPort</code> This port doesn't exist.</p> <p><code>serErrNotOpen</code> The serial port is not open.</p> <p><code>serErrNoDevicesAvail</code> No serial devices could be found.</p> <p><code>serErrNotSupported</code> The specified op code is not supported in the current configuration.</p>
<b>Comments</b>	<a href="#">Table 65.1</a> shows what to pass for the valueP and valueLenP parameters for each of the operation codes. Control codes not listed do not use these parameters. See <a href="#">SrmCtlEnum</a> for a complete list of control codes.

## Serial Manager

### *SrmControl*

---

**Table 65.1 SrmControl Parameters**

Operation Code	Parameters
srmCtlSetBaudRate	→ valueP = Pointer to Int32 (baud rate) → valueLenP = Pointer to sizeof(Int32)
srmCtlGetBaudRate	← valueP = Pointer to Int32 (baud rate) ← valueLenP = Pointer to Int16
srmCtlSetFlags	→ valueP = Pointer to UInt32 (bitfield; see <a href="#">Serial Settings Constants</a> ) → valueLenP = Pointer to sizeof(UInt32)
srmCtlGetFlags	← valueP = Pointer to UInt32 (bitfield) ← valueLenP = Pointer to Int16
srmCtlSetCtsTimeout	→ valueP = Pointer to Int32 (timeout value) → valueLenP = Pointer to sizeof(Int32)
srmCtlGetCtsTimeout	← valueP = Pointer to Int32 (timeout value) ← valueLenP = Pointer to Int16
srmCtlUserDef	↔ valueP = Pointer passed to the serial or virtual driver ↔ valueLenP = Pointer to sizeof(Int32)
	For a serial driver, these pointers are passed to the driver's control function and they contain that functions return values (if any) upon return.

**Table 65.1 SrmControl Parameters (*continued*)**

Operation Code	Parameters
srmCtlGetOptimalTransmitSize	<p>← <i>valueP</i> = Pointer to <i>Int32</i></p> <p>← <i>valueLenP</i> = Pointer to <i>sizeof(Int32)</i></p> <p>If an error is returned by <i>SrmControl</i>, no buffering should be done. If <i>valueP</i> points to zero, buffering is requested, but the transmitting application cannot determine the buffer size. If <i>valueP</i> points to a number &gt; 0, then try to send data in blocks of this number of bytes, as this is the most efficient block size for this particular device.</p>
srmCtlSetDTRAsserted	<p>→ <i>valueP</i> = Pointer to <i>Boolean</i> indicating whether to enable or disable DTR.</p> <p>→ <i>valueLenP</i> = Pointer to <i>sizeof(Boolean)</i></p>
srmCtlGetDTRAsserted	<p>← <i>valueP</i> = Pointer to <i>Boolean</i> indicating whether DTR is enabled.</p> <p>← <i>valueLenP</i> = Pointer to <i>Int16</i></p>
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmCustomControl()</a>

## **SrmCustomControl Function**

<b>Purpose</b>	Performs a custom serial control function.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<pre>Err SrmCustomControl (UInt16 portId,     UInt16 opCode, UInt32 creator, void *valueP,     UInt16 *valueLenP)</pre>
<b>Parameters</b>	<p>→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>→ <i>opCode</i> Control operation to perform. The op code must be greater than <code>srmCtlCustom</code>.</p> <p>→ <i>creator</i> Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.</p> <p>↔ <i>valueP</i> Pointer to a value to use for the operation.</p> <p>↔ <i>valueLenP</i> Pointer to the size of <i>*valueP</i>.</p>
<b>Returns</b>	<p>This function returns the following error codes:</p> <p><code>errNone</code> No error.</p> <p><code>serErrNotSupported</code> The port is not the foreground port.</p> <p><code>serErrBadPort</code> This port doesn't exist.</p> <p><code>serErrNotOpen</code> The serial port is not open.</p> <p><code>serErrNoDevicesAvail</code> No serial devices could be found.</p>
<b>Comments</b>	This function is a mechanism for a virtual driver to create control codes specific to that driver, allowing for the support of new technologies that have interfaces through the Serial Manager.

This function simply forwards the `opCode` and any `valueP` parameter to the virtual driver for the port. The virtual driver may return its own error code if the `opCode` or the input in `valueP` is invalid.

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

**See Also** [SrmControl\(\)](#)

## SrmExtOpen Function

**Purpose** Opens a foreground port connection with the specified configuration.

**Declared In** `SerialMgr.h`

**Prototype**

```
Err SrmExtOpen (UInt32 port,
                SrmOpenConfigType *configP, UInt16 configSize,
                UInt16 *newPortIdP)
```

**Parameters**

- *port*  
The four-character port name (such as 'ircm' or 'u328') or logical port number to be opened. (See [Port Constants](#).)
- *configP*  
Pointer to the configuration structure specifying the serial port's properties. See [SrmOpenConfigType](#).
- *configSize*  
The size of the configuration structure pointed to by *configP*.
- ← *newPortIdP*  
Contains the port ID to be passed to other Serial Manager functions.

**Returns** This function returns the following error codes:

`errNone`

No error.

`serErrBadPort`

The port parameter does not specify a valid port.

`serErrBadParam`

The *configP* parameter is NULL.

## Serial Manager

### *SrmExtOpenBackground*

---

`serErrAlreadyOpen`

The Serial Manager already has a port open.

`memErrNotEnoughSpace`

There was not enough memory available to open the port.

**Comments** Do not keep the port open any longer than necessary. An open serial port consumes more energy from the device's batteries.

The values specified in the `configP` parameter depend on the type of connection being made. For RS-232 connections, you specify the baud rate but not a purpose. For USB connections, you specify a purpose but not a baud rate.

A newly opened port has its line errors cleared, the default CTS timeout set (specified by the constant `srmDefaultCTSTimeout`), a 512-byte receive queue allocated, 1 stop bit, 8 bits per character, RTS enabled, and flow control enabled. To increase the receive queue size, use [SrmSetReceiveBuffer\(\)](#). To change the other serial port settings, use [SrmControl\(\)](#).

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present. The `SrmExtOpen` function replaces the [SrmOpen\(\)](#) function.

**See Also** [SrmOpen\(\)](#), [SrmExtOpenBackground\(\)](#)

## SrmExtOpenBackground Function

**Purpose** Opens a port with the specified configuration in the background. Background ports relinquish control when another task opens the port with the [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#) call.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmExtOpenBackground (UInt32 port,  
SrmOpenConfigType *configP, UInt16 configSize,  
UInt16 *newPortIdP)`

**Parameters**  $\rightarrow$  *port*

Physical or logical port number to be opened. See [Port Constants](#) for more information.

$\rightarrow$  *configP*

Pointer to the configuration structure specifying the serial port's properties. See [SrmOpenConfigType](#).

→ *configSize*

The size of the configuration structure pointed to by *configP*.

← *newPortIdP*

Contains the port ID to be passed to other Serial Manager functions.

**Returns** This function returns the following error codes:

*errNone*

No error.

*serErrAlreadyOpen*

This port already has an installed background owner.

*serErrBadPort*

This port doesn't exist.

*serErrNotSupported*

This type of port cannot be opened in the background.

*serErrBadParam*

The *configP* parameter is NULL.

*memErrNotEnoughSpace*

There was not enough memory available to open the port.

**Comments** This function is provided to support tasks that want to use a serial device to receive data only when no other task is using the port.

If a background port is forced to surrender control of the hardware as a result of another task opening a foreground connection, all buffers for the background port are flushed. After this active task closes the port, active control of the port is returned to the background task. Only one task can have background ownership of the port.

Note that background ports have limited functionality: they can only receive data and notify owning clients of what data has been received.

The values specified in the *configP* parameter depend on the type of connection being made. For RS-232 connections, you specify the baud rate but not a purpose. For USB connections, you specify a purpose but not a baud rate.

## Serial Manager

### *SrmGetDeviceCount*

---

- Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present. The `SrmExtOpenBackground` function replaces the [SrmOpenBackground\(\)](#) function.
- See Also** [SrmOpen\(\)](#), [SrmExtOpen\(\)](#)

## SrmGetDeviceCount Function

- Purpose** Returns the number of available serial devices.
- Declared In** `SerialMgr.h`
- Prototype** `Err SrmGetDeviceCount (UInt16 *numOfDevicesP)`
- Parameters**  $\leftarrow$  *numOfDevicesP*  
Pointer to address where the number of serial devices is returned.
- Returns** `errNone`  
No error.
- Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.
- See Also** [SrmGetDeviceInfo\(\)](#)

## SrmGetDeviceInfo Function

- Purpose** Returns information about a serial device.
- Declared In** `SerialMgr.h`
- Prototype** `Err SrmGetDeviceInfo (UInt32 deviceID, DeviceInfoType *deviceInfoP)`
- Parameters**  $\rightarrow$  *deviceID*  
ID of serial device to get information for. You can pass a zero-based index (0, 1, 2, ...), a valid port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#), or a 4-character port name (such as 'u328', 'u650', or 'ircm'). See [Port Constants](#).
- $\leftarrow$  *deviceInfoP*  
Pointer to a [DeviceInfoType](#) structure where information about the device is returned.

<b>Returns</b>	This function returns the following error codes:  <code>errNone</code> No error.  <code>serErrBadPort</code> This port doesn't exist.  <code>serErrNoDevicesAvail</code> The Serial Manager cannot find any serial devices.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmGetDeviceCount()</a>

## SrmGetStatus Function

<b>Purpose</b>	Returns status information about the serial hardware.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmGetStatus (UInt16 portId,                   UInt32 *statusFieldP, UInt16 *lineErrsP)</code>
<b>Parameters</b>	<p>→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>← <i>statusFieldP</i> Pointer to address where hardware status information for the port is returned. This is a 32-bit field using the flags described in <a href="#">Status Constants</a>.</p> <p>← <i>lineErrsP</i> Pointer to address where the number of line errors for the port is returned. The line error flags are described in <a href="#">Line Error Constants</a>.</p>
<b>Returns</b>	This function returns the following error codes:  <code>errNone</code> No error.  <code>serErrBadPort</code> This port doesn't exist.  <code>serErrNotSupported</code> The port is a yielded port.

## Serial Manager

### *SrmOpen*

---

`serErrNoDevicesAvail`

No serial devices could be found.

**Comments** Typically, `SrmGetStatus` is called to retrieve the line errors for the port if some of the send and receive functions return a `serErrLineErr` error code.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## SrmOpen Function

**Purpose** Opens a foreground port connection with the specified port name or logical port number.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmOpen (UInt32 port, UInt32 baud,  
                  UInt16 *newPortIdP)`

**Parameters**

- *port*  
The four-character port name or logical port number to be opened. See [Port Constants](#) for more information.
- *baud*  
Initial baud rate of port.
- ← *newPortIdP*  
Contains the port ID to be passed to other Serial Manager functions.

**Returns** This function returns the following error codes:

`errNone`

No error.

`serErrAlreadyOpen`

This port already has an installed foreground owner.

`serErrBadPort`

This port doesn't exist.

`memErrNotEnoughSpace`

There was not enough memory available to open the port.

**Comments** Only one application or task may have access to a particular serial port at any time.

- Do not keep the port open any longer than necessary. An open serial port consumes more energy from the device's batteries.
- Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.
- If [New Serial Manager Feature Set Version 2](#) is present, the `SrmOpen` function is replaced by [SrmExtOpen\(\)](#). `SrmOpen` is supported for backward compatibility.
- See Also** [SrmOpenBackground\(\)](#)

## SrmOpenBackground Function

- Purpose** Allows a task to open, initialize, and use the port, but always relinquishes control of the port when another task opens the port with the [SrmOpen\(\)](#) call.
- Declared In** `SerialMgr.h`
- Prototype** `Err SrmOpenBackground (UInt32 port, UInt32 baud, UInt16 *newPortIdP)`
- Parameters**
- *port*  
The four-character port name or logical port number to be opened. See [Port Constants](#) for more information.
  - *baud*  
Initial baud rate of port.
  - ← *newPortIdP*  
Contains the port ID to be passed to other Serial Manager functions.
- Returns** This function returns the following error codes:
- `errNone`  
No error.
  - `serErrAlreadyOpen`  
This port already has an installed background owner.
  - `serErrBadPort`  
This port doesn't exist.
  - `memErrNotEnoughSpace`  
There was not enough memory available to open the port.

## Serial Manager

### *SrmPrimeWakeupHandler*

---

<b>Comments</b>	<p>This function is provided to support tasks that want to use a serial device to receive data only when no other task is using the port.</p> <p>If a background port is forced to surrender control of the hardware as a result of another task opening a foreground connection, all buffers for the background port are flushed. After this active task closes the port, active control of the port is returned to the background task. Only one task can have background ownership of the port.</p> <p>Note that background ports have limited functionality: they can only receive data and notify owning clients of what data has been received.</p>
<b>Compatibility</b>	<p>Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.</p> <p>If <a href="#">New Serial Manager Feature Set Version 2</a> is present, the <code>SrmOpenBackground</code> function is replaced by <a href="#">SrmExtOpenBackground()</a>. <code>SrmOpenBackground</code> is supported for backward compatibility.</p>
<b>See Also</b>	<a href="#">SrmOpen()</a>

## SrmPrimeWakeupHandler Function

<b>Purpose</b>	Sets the number of received bytes that triggers a call to the wakeup handler function.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmPrimeWakeupHandler (UInt16 portId,                                 UInt16 minBytes)</code>
<b>Parameters</b>	<p>→ <i>portId</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>→ <i>minBytes</i> Number of bytes that must be received before wakeup handler is called. Typically, this is set to 1.</p>
<b>Returns</b>	<p>This function returns the following error codes:</p> <p><code>errNone</code> No error.</p>

	<code>serErrBadPort</code> This port doesn't exist.
	<code>serErrNotOpen</code> The port is not open.
	<code>serErrNoDevicesAvail</code> No serial devices could be found.
<b>Comments</b>	This function primes a wakeup handler installed by <a href="#">SrmSetWakeupHandler()</a> .
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmSetWakeupHandler()</a> , <a href="#">WakeupHandlerProcPtr()</a>

## SrmReceive Function

<b>Purpose</b>	Receives a specified number of bytes.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>UInt32 SrmReceive (UInt16 portId, void *rcvBufP, UInt32 count, Int32 timeout, Err *errP)</code>
<b>Parameters</b>	<p>→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>← <i>rcvBufP</i> Pointer to buffer where received data is to be returned.</p> <p>→ <i>count</i> Length of data buffer (in bytes). This specifies the number of bytes to receive.</p> <p>→ <i>timeout</i> The amount of time (in ticks) that the Serial Manager waits to receive the requested block of data. At the end of the timeout, data received up to that time is returned.</p> <p>← <i>errP</i> Error code.</p>
<b>Returns</b>	Number of bytes of data actually received.
<b>Comments</b>	The following error codes can be returned in <code>errP</code> :

## Serial Manager

### *SrmReceiveCheck*

---

`errNone`

No error.

`serErrBadPort`

This port doesn't exist.

`serErrNotOpen`

The port is not open.

`serErrTimeOut`

Unable to receive data within the specified timeout period.

`serErrConfigurationFailed`

The port needs time to configure, and the configuration has failed.

`serErrNotSupported`

The port is not the foreground port.

`serErrConfigurationFailed`

The port could not configure itself.

`serErrLineErr`

A line error occurred during the receipt of data. Use [SrmGetStatus\(\)](#) to obtain the exact line error.

`serErrNoDevicesAvail`

No serial devices could be found.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmReceiveCheck\(\)](#), [SrmReceiveFlush\(\)](#),  
[SrmReceiveWait\(\)](#)

## SrmReceiveCheck Function

**Purpose** Checks the receive FIFO and returns the number of bytes in the serial receive queue.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmReceiveCheck (UInt16 portId,  
                          UInt32 *numBytesP)`

**Parameters**  $\rightarrow$  *portID*  
Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).

	$\leftarrow numBytesP$ Number of bytes in the receive queue.
<b>Returns</b>	This function returns the following error codes: <code>errNone</code> No error. <code>serErrBadPort</code> This port doesn't exist. <code>serErrNotOpen</code> The port is not open. <code>serErrLineErr</code> A line error has occurred. Use <a href="#">SrmGetStatus()</a> to obtain the exact line error.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmReceive()</a> , <a href="#">SrmReceiveFlush()</a> , <a href="#">SrmReceiveWait()</a>

## SrmReceiveFlush Function

<b>Purpose</b>	Flushes the receive FIFOs.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<pre>Err SrmReceiveFlush (UInt16 portId,                     Int32 timeout)</pre>
<b>Parameters</b>	$\rightarrow portId$ Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a> . $\rightarrow timeout$ Timeout value, in ticks.
<b>Returns</b>	This function returns the following error codes: <code>errNone</code> No error. <code>serErrBadPort</code> This port doesn't exist. <code>serErrNotOpen</code> The port is not open.

## Serial Manager

### *SrmReceiveWait*

---

`serErrNotSupported`

The port is not the foreground port.

`serErrNoDevicesAvail`

No serial devices could be found.

#### Comments

The `timeout` value forces this function to wait a period of ticks after flushing the port to see if more data shows up to be flushed. If more data arrives within the timeout period, the port is flushed again and the timeout counter is reset and waits again. The function only exits after no more bytes are received by the port for the full timeout period since the last flush of the port. To avoid this waiting behavior, specify 0 for the timeout period.

Any errors on the line are cleared before this function returns.

#### Compatibility

Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

#### See Also

[SrmReceive\(\)](#), [SrmReceiveCheck\(\)](#), [SrmReceiveWait\(\)](#)

## SrmReceiveWait Function

#### Purpose

Waits until some number of bytes of data have arrived into the serial receive queue, then returns.

#### Declared In

`SerialMgr.h`

#### Prototype

```
Err SrmReceiveWait (UInt16 portId, UInt32 bytes,
                   Int32 timeout)
```

#### Parameters

→ *portID*

Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).

→ *bytes*

Number of bytes to wait for.

→ *timeout*

Timeout value, in ticks.

#### Returns

This function returns the following error codes:

`errNone`

No error.

`serErrBadPort`

This port doesn't exist.

`serErrNotOpen`

The port is not open.

`serErrTimeout`

Unable to receive data within the specified timeout period.

`serErrNotSupported`

The port is not the foreground port.

`serErrBadParam`

The bytes parameter exceeds the size of the receive queue. Use [SrmSetReceiveBuffer\(\)](#) to increase the size of the receive queue.

`serErrLineErr`

A line error occurred during the receipt of data. Use [SrmGetStatus\(\)](#) to obtain the exact line error.

`serErrNoDevicesAvail`

No serial devices could be found.

**Comments** If this function returns no error, the application can either check the number of bytes currently in the receive queue (using [SrmReceiveCheck\(\)](#)) or it can just specify a buffer and receive the data by calling [SrmReceive\(\)](#).

Do not call `SerReceiveWait` from within a wakeup handler. If you do, the `serErrTimeout` error is returned.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmReceive\(\)](#), [SrmReceiveCheck\(\)](#), [SrmReceiveFlush\(\)](#)

## **SrmReceiveWindowClose Function**

**Purpose** Closes direct access to the Serial Manager's receive queue.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmReceiveWindowClose (UInt16 portId,  
                                  UInt32 bytesPulled)`

**Parameters**   
→ *portId*  
Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).  
→ *bytesPulled*  
Number of bytes the application read from the receive queue.

## Serial Manager

### *SrmReceiveWindowOpen*

---

<b>Returns</b>	This function returns the following error codes:  <code>errNone</code> No error.  <code>serErrBadPort</code> This port doesn't exist.  <code>serErrNotOpen</code> The port is not open.  <code>serErrNotSupported</code> The port is not the foreground port.  <code>serErrNoDevicesAvail</code> No serial devices could be found.
<b>Comments</b>	Call this function when the application has read as many bytes as it needs out of the receive queue or it has read all the available bytes.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmReceiveWindowOpen()</a>

## SrmReceiveWindowOpen Function

<b>Purpose</b>	Provides direct access to the Serial Manager's receive queue.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmReceiveWindowOpen (UInt16 portId,                               UInt8 **bufPP, UInt32 *sizeP)</code>
<b>Parameters</b>	 → <i>portId</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a> .  ← <i>bufPP</i> Pointer to a pointer to the receive buffer.  ← <i>sizeP</i> Available bytes in buffer.
<b>Returns</b>	This function returns the following error codes:  <code>errNone</code> No error.

`serErrBadPort`

This port doesn't exist.

`serErrNotOpen`

The port is not open.

`serErrNotSupported`

The port is not the foreground port.

`serErrLineErr`

The data in the queue contains line errors.

`serErrNoDevicesAvail`

No serial devices could be found.

**Comments** This function lets applications directly access the Serial Manager's receive queue to eliminate buffer copying by the Serial Manager. This access is a "back door" route to the received data. After retrieving data from the buffer, the application must call [`SrmReceiveWindowClose\(\)`](#).

Applications that want to empty the receive buffer entirely should call the `SrmReceiveWindowOpen` and `SrmReceiveWindowClose` functions repeatedly until the buffer size returned is 0.

---

**IMPORTANT:** Once an application calls `SrmReceiveWindowOpen`, it should not attempt to receive data via the normal method of calling [`SrmReceive\(\)`](#) or [`SrmReceiveWait\(\)`](#), as these functions interfere with direct access to the receive queue.

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [`SrmReceiveWindowClose\(\)`](#)

## SrmSend Function

<b>Purpose</b>	Sends a block of data out the specified port.
<b>Declared In</b>	SerialMgr.h
<b>Prototype</b>	<pre>UInt32 SrmSend (UInt16 portId, const void *bufP,                 UInt32 count, Err *errP)</pre>
<b>Parameters</b>	<p>→ <i>portID</i> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a>.</p> <p>→ <i>bufp</i> Pointer to data to send.</p> <p>→ <i>count</i> Length of data buffer, in bytes.</p> <p>← <i>errP</i> Error code. See the Comments section for details.</p>
<b>Returns</b>	Number of bytes of data actually sent.
<b>Comments</b>	<p>When SrmSend returns, you should check the value returned in the <i>errP</i> parameter. If <i>errNone</i>, then the entire data buffer was sent. If not <i>errNone</i>, then the result equals the number of bytes sent before the error occurred. The possible error values are:</p> <p><i>errNone</i> No error.</p> <p><i>serErrBadPort</i> This port doesn't exist.</p> <p><i>serErrNotOpen</i> The port is not open.</p> <p><i>serErrTimeOut</i> Unable to send data within the specified CTS timeout period.</p> <p><i>serErrNoDevicesAvail</i> No serial devices could be found.</p> <p><i>serErrConfigurationFailed</i> The port configuration has failed.</p> <p><i>serErrNotSupported</i> The specified port is not the foreground port.</p>

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSendCheck\(\)](#), [SrmSendFlush\(\)](#), [SrmSendWait\(\)](#)

## SrmSendCheck Function

**Purpose** Checks the transmit FIFO and returns the number of bytes left to be sent.

**Declared In** SerialMgr.h

**Prototype** Err SrmSendCheck (UInt16 portId,  
                        UInt32 \*numBytesP)

**Parameters** → *portID*  
                    Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).  
                    ← *numBytesP*  
                    Number of bytes left in the FIFO queue.

**Returns** This function returns the following error codes:

errNone  
    No error.  
serErrBadPort  
    This port doesn't exist.  
serErrNotOpen  
    The port is not open.  
serErrNotSupported  
    This feature not supported by the hardware.  
serErrNoDevicesAvail  
    No serial devices could be found.

**Comments** Not all serial devices support this feature.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSend\(\)](#), [SrmSendFlush\(\)](#), [SrmSendWait\(\)](#)

## **SrmSendFlush Function**

<b>Purpose</b>	Flushes the transmit FIFO.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmSendFlush (UInt16 portId)</code>
<b>Parameters</b>	<code>→ portID</code> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a> .
<b>Returns</b>	This function returns the following error codes: <code>errNone</code> No error. <code>serErrBadPort</code> This port doesn't exist. <code>serErrNotOpen</code> The port is not open. <code>serErrNotSupported</code> The port is not the foreground port. <code>serErrNoDevicesAvail</code> No serial devices could be found.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmSend()</a> , <a href="#">SrmSendCheck()</a> , <a href="#">SrmSendWait()</a>

## **SrmSendWait Function**

<b>Purpose</b>	Waits until all previous data has been sent from the transmit FIFO, then returns.
<b>Declared In</b>	<code>SerialMgr.h</code>
<b>Prototype</b>	<code>Err SrmSendWait (UInt16 portId)</code>
<b>Parameters</b>	<code>→ portID</code> Port ID returned from <a href="#">SrmOpen()</a> or <a href="#">SrmExtOpen()</a> .
<b>Returns</b>	This function returns the following error codes: <code>errNone</code> No error.

`serErrBadPort`

This port doesn't exist.

`serErrNotOpen`

The port is not open.

`serErrTimeOut`

Unable to send data within the CTS timeout period.

`serErrNotSupported`

The port is not the foreground port.

`serErrNoDevicesAvail`

No serial devices could be found.

**Comments** Consider calling this function if your software needs to detect when all data has been transmitted by [SrmSend\(\)](#). The `SrmSend` function blocks until all data has been transmitted or a timeout occurs. A subsequent call to `SrmSendWait` blocks until all data queued up for transmission has been transmitted or until another CTS timeout occurs (if CTS handshaking is enabled).

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSend\(\)](#), [SrmSendCheck\(\)](#), [SrmSendFlush\(\)](#)

## SrmSetReceiveBuffer Function

**Purpose** Installs a new buffer into the Serial Manager's receive queue.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmSetReceiveBuffer (UInt16 portId,  
void *bufP, UInt16 bufSize)`

**Parameters** → *portID*

Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).

→ *bufP*

Pointer to new receive buffer. Ignored if `bufSize` is `NULL`.

→ *bufSize*

Size of new receive buffer in bytes. To remove this buffer and allocate a new default buffer (512 bytes), specify `NULL`.

**Returns** This function returns the following error codes:

## Serial Manager

### *SrmSetWakeupHandler*

---

`errNone`

No error.

`serErrBadPort`

This port doesn't exist.

`serErrNotOpen`

This port is not open.

`memErrNotEnoughSpace`

Not enough memory to allocate default buffer.

`serErrNoDevicesAvail`

No serial devices could be found.

#### Comments

The buffer that you pass to this function must remain allocated while you have the serial port open. Before you close the serial port, you must restore the default queue by calling `SrmSetReceiveBuffer` with `NULL` as the `bufP` and `bufSize` arguments.

---

**IMPORTANT:** Applications must install the default buffer before closing the port (or disposing of the new receive queue).

---

#### Compatibility

Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## SrmSetWakeupHandler Function

#### Purpose

Installs a wakeup handler.

#### Declared In

`SerialMgr.h`

#### Prototype

```
Err SrmSetWakeupHandler (UInt16 portId,  
    WakeupHandlerProcPtr procP, UInt32 refCon)
```

#### Parameters

→ *portID*

Port ID returned from [SrmOpen\(\)](#) or [SrmExtOpen\(\)](#).

→ *procP*

Pointer to a [WakeupHandlerProcPtr\(\)](#) function. Specify `NULL` to remove a handler.

→ *refCon*

User-defined data that is passed to the wakeup handler function. This can be a pointer or not.

**Returns** This function returns the following error codes:

*errNone*

No error.

*serErrBadPort*

This port doesn't exist.

*serErrNotOpen*

The port is not open.

*serErrNoDevicesAvail*

No serial devices could be found.

**Comments** The wakeup handler is a function in your application that you want to be called whenever there is data ready to be received on the specified port.

The wakeup handler function will not become active until it is primed with a number of bytes that is greater than 0, by the [SrmPrimeWakeupHandler\(\)](#) function. Every time a wakeup handler is called, it must be re-primed (using [SrmPrimeWakeupHandler\(\)](#) in order to be called again.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmPrimeWakeupHandler\(\)](#), [WakeupHandlerProcPtr\(\)](#)

## Serial Manager Application-Defined Functions

### WakeupHandlerProcPtr Function

<b>Purpose</b>	Called after some number of bytes are received by the Serial Manager's interrupt function.
<b>Declared In</b>	SerialMgr.h
<b>Prototype</b>	void (*WakeupHandlerProcPtr) (UInt32 refCon)
<b>Parameters</b>	→ <i>refCon</i> User-defined data passed from the <a href="#">SrmSetWakeupHandler()</a> function.
<b>Returns</b>	Returns nothing.
<b>Comments</b>	This handler function is installed by calling <a href="#">SrmSetWakeupHandler()</a> . The number of bytes after which it is called is specified by <a href="#">SrmPrimeWakeupHandler()</a> .
<hr/> <b>IMPORTANT:</b> Because wakeup handlers are called during interrupt time, they cannot call <b>any</b> Palm OS® system functions, including <a href="#">SrmReceive()</a> , that may block the system in any way. Wakeup handlers should also be very short so as to reduce interrupt latency. <hr/>	
Two common implementations of wakeup handlers include:	
<ul style="list-style-type: none"><li>• Calling <a href="#">EvtWakeup()</a>, which causes any pending EvtGetEvent call to return and then sends a nilEvent to the current application.</li><li>• Using <a href="#">SrmReceiveWindowOpen()</a> and <a href="#">SrmReceiveWindowClose()</a> to gain direct access to the receive queue without blocking.</li></ul>	
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.
<b>See Also</b>	<a href="#">SrmPrimeWakeupHandler()</a> , <a href="#">SrmSetWakeupHandler()</a>

# Old Serial Manager

---

This chapter provides reference material for the serial manager API:

- [Serial Manager Data Structures](#)
- [Serial Manager Functions](#)

The header file `SerialMgrOld.h` declares the serial manager API. For more information on the serial manager, see the chapter “[Serial Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**NOTE:** The API described in this chapter is obsolete if the [New Serial Manager Feature Set](#) is present. The API is still supported for backward compatibility; however, the Serial Manager APIs are preferred.

---

## Serial Manager Data Structures

### SerCtlEnum Enum

To perform a control function, applications call [SerControl\(\)](#), which performs one of the control operations specified by `SerCtlEnum`, which has the following elements:

Element	Description
<code>serCtlFirstReserved = 0</code>	Reserve 0
<code>serCtlStartBreak</code>	Turn RS232 break signal on. Applications have to make sure that the break is set long enough to generate a value BREAK!  <code>valueP = 0; valueLenP = 0</code>

## Old Serial Manager

### *SerCtlEnum*

---

Element	Description
<code>serCtlStopBreak</code>	Turn RS232 break signal off: <code>valueP = 0; valueLenP = 0</code>
<code>serCtlBreakStatus</code>	Get RS232 break signal status (on or off): <code>valueP = ptr to Word for returning status</code> (0 = off, !0 = on)  <code>*valueLenP = sizeof(Word)</code>
<code>serCtlStartLocalLoopback</code>	Start local loopback test; <code>valueP = 0, valueLenP = 0</code>
<code>serCtlStopLocalLoopback</code>	Stop local loopback test <code>valueP = 0, valueLenP = 0</code>
<code>serCtlMaxBaud</code>	<code>valueP = ptr to DWord for returned baud</code> <code>*valueLenP = sizeof(DWord)</code>
<code>serCtlHandshakeThreshold</code>	Retrieve HW handshake threshold; this is the maximum baud rate that does not require hardware handshaking <code>valueP = ptr to DWord for returned baud</code> <code>*valueLenP = sizeof(DWord)</code>
<code>serCtlEmuSetBlockingHook</code>	Set a blocking hook routine.  <hr/> <b>WARNING!</b> WARNING: For use with the Simulator on Mac OS only: NOT SUPPORTED ON THE PALM DEVICE. <hr/>
	<code>valueP = ptr to SerCallbackEntryType</code> <code>*valueLenP = sizeof(SerCallbackEntryType)</code> Returns the old settings in the first argument.
<code>serCtlLAST</code>	Add new address entries before this one.

## SerSettingsType Struct

**Purpose** The SerSettingsType structure defines serial port attributes; it is used by the calls [SerGetSettings\(\)](#) and [SerSetSettings\(\)](#). The SerSettingsPtr type points to a SerSettingsType structure.

**Prototype**

```
typedef struct SerSettingsType {  
    UInt32 baudRate;  
    UInt32 flags;  
    Int32 ctsTimeout;  
} SerSettingsType;  
  
typedef SerSettingsType* SerSettingsPtr;
```

### Field Descriptions

baudRate	Baud rate
flags	Miscellaneous settings
ctsTimeout	Maximum number of ticks to wait for CTS to become asserted before transmitting; used only when configured with the serSettingsFlagCTSAutoM flag.

## Serial Manager Functions

### SerClearErr Function

**Purpose** Reset the serial port's line error status.

**Declared In** SerialMgrOld.h

**Prototype** Err SerClearErr (UInt16 refNum)

**Parameters**  $\rightarrow$  *refNum*  
The serial library reference number.

**Returns** 0  
No error.

## Old Serial Manager

### *SerClose*

---

- Comments** Call `SerClearErr` only after a serial manager function (`SerReceive`, `SerReceiveCheck`, `SerSend`, etc.) returns with the error code `serErrLineErr`.
- The reason for this is that `SerClearErr` resets the serial port. So, if `SerClearErr` is called unconditionally while a byte is coming into the serial port, that byte is guaranteed to become corrupted.
- The right strategy is to always check the error code returned by a serial manager function. If it's `serErrLineErr`, call `SerClearErr` immediately. However, don't make unsolicited calls to `SerClearErr`.
- When you get `serErrLineErr`, consider flushing the receive queue for a fraction of a second by calling `SerReceiveFlush`. `SerReceiveFlush` calls `SerClearErr` for you.

## SerClose Function

- Purpose** Release the serial port previously acquired by `SerOpen`.
- Declared In** `SerialMgrOld.h`
- Prototype** `Err SerClose (UInt16 refNum)`
- Parameters**  $\rightarrow$  *refNum*  
Serial library reference number.
- Returns** 0  
No error.
- `serErrNotOpen`  
Port wasn't open.
- `serErrStillOpen`  
Port still held open by another process.
- Comments** Releases the serial port and shuts down serial port hardware if the open count has reached 0. Open serial ports consume more energy from the device's batteries; it's therefore essential to keep a port open only as long as necessary.
- Caveat** Don't call `SerClose` unless the return value from `SerOpen()` was 0 (zero) or `serErrAlreadyOpen`.
- See Also** [`SerOpen\(\)`](#)

## SerControl Function

<b>Purpose</b>	Perform a control function.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>Err SerControl (UInt16 refNum, UInt16 op,                void *valueP, UInt16 *valueLenP)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Reference number of library.</p> <p>→ <i>op</i> Control operation to perform (SerCtlEnum).</p> <p>↔ <i>valueP</i> Pointer to value for operation.</p> <p>↔ <i>valueLenP</i> Pointer to size of value.</p>
<b>Returns</b>	<p>0 No error.</p> <p>serErrBadParam Invalid parameter (unknown).</p> <p>serErrNotOpen Library not open.</p>
<b>Comments</b>	<p>This function provides extensible control features for the serial manager. You can</p> <ul style="list-style-type: none"><li>• Turn on/off the RS232 break signal and check its status.</li><li>• Perform a local loopback test.</li><li>• Get the maximum supported baud rate.</li><li>• Get the hardware handshake threshold baud rate.</li></ul>
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.

## SerGetSettings Function

<b>Purpose</b>	Fill in the <a href="#">SerSettingsType</a> structure with current serial port attributes.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>Err SerGetSettings (UInt16 refNum,                     SerSettingsPtr settingsP)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>↔ <i>settingsP</i> Pointer to <a href="#">SerSettingsType</a> structure to be filled in.</p>
<b>Returns</b>	<p>0 No error.</p> <p>serErrNotOpen The port wasn't open.</p>
<b>Comments</b>	<p>The information returned by this call includes the current baud rate, CTS timeout, handshaking options, and data format options.</p> <p>See the <a href="#">SerSettingsType</a> structure for more details.</p>
<b>See Also</b>	<a href="#">SerSend()</a>

## SerGetStatus Function

<b>Purpose</b>	Return the pending line error status for errors that have been detected since the last time <a href="#">SerClearErr()</a> was called.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>UInt16 SerGetStatus (UInt16 refNum,                     Boolean *ctsOnP, Boolean *dsrOnP)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>ctsOnP</i> Pointer to location for storing a Boolean value.</p> <p>→ <i>dsrOnP</i> Pointer to location for storing a Boolean value.</p>

**Returns** Returns any combination of the following constants, bitwise OR'ed together:

`serLineErrorParity`  
Parity error.

`serLineErrorHWOverrun`  
Hardware overrun.

`serLineErrorFraming`  
Framing error.

`serLineErrorBreak`  
Break signal detected.

`serLineErrorHShake`  
Line handshake error.

`serLineErrorSWOverrun`  
Software overrun.

**Comments** When another serial manager function returns an error code of `serErrLineErr`, `SerGetStatus` can be used to find out the specific nature of the line error(s).  
  
The values returned via `ctsOnP` and `dsrOnP` are not meaningful in the present version of the software

**See Also** [`SerClearErr\(\)`](#)

## SerOpen Function

**Purpose** Acquire and open a serial port with given baud rate and default settings.

**Declared In** `SerialMgrOld.h`

**Prototype** `Err SerOpen (UInt16 refNum, UInt16 port, UInt32 baud)`

**Parameters**

- *refNum*  
Serial library reference number.
- *port*  
Port number.
- *baud*  
Baud rate.

## Old Serial Manager

### *SerOpen*

---

**Returns**     0

No error.

`serErrAlreadyOpen`

Port was open. Enables port sharing by “friendly” clients (not recommended).

`serErrBadParam`

Invalid parameter.

`memErrNotEnoughSpace`

Insufficient memory.

**Comments**

Acquires the serial port, powers it up, and prepares it for operation. To obtain the serial library reference number, call [`SysLibFind\(\)`](#) with “Serial Library” as the library name. This reference number must be passed as a parameter to all serial manager functions. The device currently contains only one serial port with port number 0 (zero).

The baud rate is an integral baud value (for example - 300, 1200, 2400, 9600, 19200, 38400, 57600, etc.). The Palm OS® device has been tested at the standard baud rates in the range of 300 - 57600 baud. Baud rates through 1 Mbit are theoretically possible. Use CTS handshaking at baud rates above 19200 (see [`SerSetSettings\(\)`](#)).

An error code of 0 (zero) or `serErrAlreadyOpen` indicates that the port was successfully opened. If the port is already open when `SerOpen` is called, the port’s open count is incremented and an error code of `serErrAlreadyOpen` is returned. This ability to open the serial port multiple times allows cooperating tasks to share the serial port. Other tasks must refrain from using the port if `serErrAlreadyOpen` is returned and close it by calling [`SerClose\(\)`](#).

## SerReceive Function

<b>Purpose</b>	Receives size bytes worth of data or returns with error if a line error or timeout is encountered.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	UInt32 SerReceive (UInt16 refNum, void *bufP, UInt32 count, Int32 timeout, Err* errP)
<b>Parameters</b>	<p>refNum Serial library reference number.</p> <p>↔ <i>bufP</i> Buffer for receiving data.</p> <p>→ <i>count</i> Number of bytes to receive.</p> <p>→ <i>timeout</i> Interbyte timeout in ticks, 0 for none, -1 forever.</p> <p>↔ <i>errP</i> For returning error code.</p>
<b>Returns</b>	<p>Number of bytes received:</p> <p>*errP = 0 No error.</p> <p>serErrLineErr RS232 line error.</p> <p>serErrTimeOut Interbyte timeout.</p>
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.

---

**NOTE:** The old versions of SerSend and SerReceive are still available as SerSend10 and SerReceive10 (not V10).

---

**See Also** [SerReceive10\(\)](#)

### SerReceive10 Function

<b>Purpose</b>	Receive a stream of bytes.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>Err SerReceive10 (UInt16 refNum, void *bufP,                  UInt32 bytes, Int32 timeout)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> The serial library reference number.</p> <p>→ <i>bufP</i> Pointer to the buffer for receiving data.</p> <p>→ <i>bytes</i> Number of bytes desired.</p> <p>→ <i>timeout</i> Interbyte time out in system ticks (-1 = forever).</p>
<b>Returns</b>	<p>0 No error. Requested number of bytes was received.</p> <p><code>serErrTimeOut</code> Interbyte time out exceeded while waiting for the next byte to arrive.</p> <p><code>serErrLineErr</code> Line error occurred (see <a href="#">SerClearErr()</a> and <a href="#">SerGetStatus()</a>).</p>
<b>Comments</b>	SerReceive blocks until all the requested data has been received or an error occurs. Because this call returns immediately without any data if line errors are pending, it is important to acknowledge the detection of line errors by calling <a href="#">SerClearErr()</a> . If you just need to retrieve all or some of the bytes which are already in the receive queue, call <a href="#">SerReceiveCheck()</a> first to get the count of bytes presently in the receive queue.
<b>Compatibility</b>	This function corresponds to the 1.0 version of SerReceive.

## SerReceiveCheck Function

<b>Purpose</b>	Return the count of bytes presently in the receive queue.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>Err SerReceiveCheck (UInt16 refNum,                     UInt32 *numBytesP)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>↔ <i>numBytesP</i> Pointer to location for returning the byte count.</p>
<b>Returns</b>	<p>0 No error.</p> <p>serErrLineErr Line error pending (see <a href="#">SerClearErr()</a> and <a href="#">SerGetStatus()</a>).</p>
<b>Comments</b>	Because this call does not return the byte count if line errors are pending, it is important to acknowledge the detection of line errors by calling <a href="#">SerClearErr()</a> .
<b>See Also</b>	<a href="#">SerReceiveWait()</a>

## SerReceiveFlush Function

<b>Purpose</b>	Discard all data presently in the receive queue and flush bytes coming into the serial port. Clear the saved error status.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>void SerReceiveFlush (UInt16 refNum,                     Int32 timeout)</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>timeout</i> Interbyte time out in system ticks (-1 = forever).</p>
<b>Returns</b>	Returns nothing.
<b>Comments</b>	<i>SerReceiveFlush</i> blocks until a timeout occurs while waiting for the next byte to arrive.

### SerReceiveWait Function

<b>Purpose</b>	Wait for at least <i>bytes</i> bytes of data to accumulate in the receive queue.
<b>Declared In</b>	<code>SerialMgrOld.h</code>
<b>Prototype</b>	<code>Err SerReceiveWait (UInt16 refNum, UInt32 bytes, Int32 timeout)</code>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>bytes</i> Number of bytes desired.</p> <p>→ <i>timeout</i> Interbyte timeout in system ticks (-1 = forever).</p>
<b>Returns</b>	<p>0 No error.</p> <p><code>serErrTimeOut</code> Interbyte timeout exceeded while waiting for next byte to arrive.</p> <p><code>serErrLineErr</code> Line error occurred (see <a href="#">SerClearErr()</a> and <a href="#">SerGetStatus()</a>).</p>
<b>Comments</b>	<p>This is the preferred method of waiting for serial input, since it blocks the current task and allows switching the processor into a more energy-efficient state.</p> <p><code>SerReceiveWait</code> blocks until the desired number of bytes accumulate in the receive queue or an error occurs. The desired number of bytes must be less than the current receive queue size. The default queue size is 512 bytes. Because this call returns immediately if line errors are pending, it is important to acknowledge the detection of line errors by calling <a href="#">SerClearErr()</a>.</p>
<b>See Also</b>	<a href="#">SerReceiveCheck()</a> , <a href="#">SerSetReceiveBuffer()</a>

## SerSend Function

<b>Purpose</b>	Send one or more bytes of data over the serial port.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	<pre>UInt32 SerSend (UInt16 refNum, void *bufP,                 UInt32 count, Err *errP</pre>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>bufP</i> Pointer to data to send.</p> <p>→ <i>count</i> Number of bytes to send.</p> <p>↔ <i>errP</i> For returning error code.</p>
<b>Returns</b>	<p>Returns the number of bytes transferred.</p> <p>Stores in <i>errP</i>:</p> <p>0 No error.</p> <p><i>serErrTimeout</i> Handshake timeout.</p> <p>The old calls worked, but they did not return enough info when they failed. The new calls (available in Palm OS v2.0 and greater) add more parameters to solve this problem and make serial communications programming simpler.</p> <p>Don't call the new functions when running on Palm OS 1.0.</p>
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.
<hr/> <b>NOTE:</b> The old versions of <code>SerSend</code> and <code>SerReceive</code> are still available as <code>SerSend10</code> and <code>SerReceive10</code> (not V10). <hr/>	
<b>See Also</b>	<a href="#">SerSend10()</a> , <a href="#">SerSendWait()</a>

## SerSend10 Function

<b>Purpose</b>	Send a stream of bytes to the serial port.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSend10 (UInt16 refNum, void *bufP, UInt32 size)
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>bufP</i> Pointer to the data to send.</p> <p>→ <i>size</i> Size (in number of bytes) of the data to send.</p>
<b>Returns</b>	<p>0 No error.</p> <p>serErrTimeout Handshake timeout (such as waiting for CTS to become asserted).</p>
<b>Comments</b>	<p>In the present implementation, SerSend10 blocks until all data is transferred to the UART or a timeout error (if CTS handshaking is enabled) occurs. Future implementations may queue up the request and return immediately, performing transmission in the background. If your software needs to detect when all data has been transmitted, see <a href="#">SerSendWait</a>.</p> <p>This routine observes the current CTS time out setting if CTS handshaking is enabled (see <a href="#">SerGetSettings()</a> and <a href="#">SerSend()</a>).</p>
<b>Compatibility</b>	This function corresponds to the 1.0 version of SerSend.
<b>See Also</b>	<a href="#">SerSend()</a> , <a href="#">SerSendWait()</a>

## SerSendFlush Function

<b>Purpose</b>	Discard all data presently in the transmit queue.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSendFlush (UInt16 refNum)
<b>Parameters</b>	→ <i>refNum</i> Serial library reference number.
<b>Returns</b>	0 No error.
<b>See Also</b>	<a href="#">SerSend()</a> , <a href="#">SerSendWait()</a>

## SerSendWait Function

<b>Purpose</b>	Wait until the serial transmit buffer empties.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSendWait (UInt16 refNum, Int32 timeout)
<b>Parameters</b>	→ <i>refNum</i> Serial library reference number.  → <i>timeout</i> Reserved for future enhancements. Set to (-1) for compatibility.
<b>Returns</b>	0 No error.  <code>serErrTimeOut</code> Handshake timeout (such as waiting for CTS to become asserted).
<b>Comments</b>	<code>SerSendWait</code> blocks until all data is transferred or a timeout error (if CTS handshaking is enabled) occurs. This routine observes the current CTS timeout setting if CTS handshaking is enabled (see <a href="#">SerGetSettings()</a> and <a href="#">SerSend()</a> ).
<b>See Also</b>	<a href="#">SerSend()</a>

## SerSetReceiveBuffer Function

<b>Purpose</b>	Replace the default receive queue. To restore the original buffer, pass <code>bufSize = 0</code> .
<b>Declared In</b>	<code>SerialMgrOld.h</code>
<b>Prototype</b>	<code>Err SerSetReceiveBuffer (UInt16 refNum, void *bufP, UInt16 bufSize)</code>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>→ <i>bufP</i> Pointer to buffer to be used as the new receive queue.</p> <p>→ <i>bufSize</i> Size of buffer, or 0 to restore the default receive queue.</p>
<b>Returns</b>	Returns 0 if successful.
<b>Comments</b>	The specified buffer needs to contain 32 extra bytes for serial manager overhead (its size should be your application's requirement plus 32 bytes). The default receive queue must be restored before the serial port is closed. To restore the default receive queue, call <a href="#">SerSetReceiveBuffer()</a> passing 0 (zero) for the buffer size. The serial manager does not free the custom receive queue.

## SerSetSettings Function

<b>Purpose</b>	Set the serial port settings; that is, change its attributes.
<b>Declared In</b>	<code>SerialMgrOld.h</code>
<b>Prototype</b>	<code>Err SerSetSettings (UInt16 refNum, SerSettingsPtr settingsP)</code>
<b>Parameters</b>	<p>→ <i>refNum</i> Serial library reference number.</p> <p>↔ <i>settingsP</i> Pointer to the filled in <a href="#">SerSettingsType</a> structure.</p>
<b>Returns</b>	0 No error.

`serErrNotOpen`  
The port wasn't open.

`serErrBadParam`  
Invalid parameter.

**Comments** The attributes set by this call include the current baud rate, CTS timeout, handshaking options, and data format options. See the definition of the [SerSettingsType](#) structure for more details.

To do 7E1 transmission, OR together:

```
serSettingsFlagBitsPerChar7 |  
serSettingsFlagParityOnM |  
serSettingsFlagParityEvenM |  
serSettingsFlagStopBits1
```

If you're trying to communicate at speeds greater than 19.2 Kbps, you need to use hardware handshaking:

```
serSettingsFlagRTSAutoM | serSettingsFlagCTSAutoM.
```

## Old Serial Manager

*SerSetSettings*

---

# Serial Link Manager

---

This chapter provides reference material for the serial link manager API. The header file `SerialLinkMgr.h` declares the serial link manager API. For more information on the serial link manager, see the chapter “[Serial Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Serial Link Manager Functions

### SlkClose Function

<b>Purpose</b>	Close down the serial link manager.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkClose (void)</code>
<b>Parameters</b>	None.
<b>Returns</b>	0 No error. <code>slkErrNotOpen</code> The serial link manager was not open.
<b>Comments</b>	When the open count reaches zero, this routine frees resources allocated by serial link manager.

## SlkCloseSocket Function

<b>Purpose</b>	Closes a socket previously opened with <a href="#">SlkOpenSocket()</a> . The caller is responsible for closing the communications library used by this socket, if necessary.
<b>Declared In</b>	SerialLinkMgr.h
<b>Prototype</b>	Err SlkCloseSocket (UInt16 socket)
<b>Parameters</b>	socket The socket ID to close.
<b>Returns</b>	0 No error. slkErrSocketNotOpen The socket was not open.
<b>Comments</b>	SlkCloseSocket frees system resources the serial link manager allocated for the socket. It does not free resources allocated and passed by the client, such as the buffers passed to <a href="#">SlkSetSocketListener()</a> ; this is the client's responsibility. The caller is also responsible for closing the communications library used by this socket.
<b>See Also</b>	<a href="#">SlkOpenSocket()</a>

## SlkFlushSocket Function

<b>Purpose</b>	Flush the receive queue of the communications library associated with the given socket.
<b>Declared In</b>	SerialLinkMgr.h
<b>Prototype</b>	Err SlkFlushSocket (UInt16 socket, Int32 timeout)
<b>Parameters</b>	→ socket Socket ID. → timeout Interbyte timeout in system ticks.
<b>Returns</b>	0 No error.

`slkErrSocketNotOpen`  
The socket wasn't open.

## SlkOpen Function

<b>Purpose</b>	Initialize the serial link manager.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkOpen (void)</code>
<b>Parameters</b>	None.
<b>Returns</b>	<code>0</code> No error. <code>slkErrAlreadyOpen</code> No error.
<b>Comments</b>	Initializes the serial link manager, allocating necessary resources. Return codes of 0 (zero) and <code>slkErrAlreadyOpen</code> both indicate success. Any other return code indicates failure. The <code>slkErrAlreadyOpen</code> function informs the client that someone else is also using the serial link manager. If the serial link manager was successfully opened by the client, the client needs to call <a href="#"><code>SlkClose()</code></a> when it finishes using the serial link manager.

## SlkOpenSocket Function

<b>Purpose</b>	Open a serial link socket and associate it with a communications library. The socket may be a known static socket or a dynamically assigned socket.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkOpenSocket (UInt16 portID,                     UInt16 *socketP, Boolean staticSocket)</code>
<b>Parameters</b>	<code>portID</code> Comm library reference number for socket. <code>socketP</code> Pointer to location for returning the socket ID.

## Serial Link Manager

### *SlkReceivePacket*

---

	<code>staticSocket</code> If TRUE, <code>*socketP</code> contains the desired static socket number to open. If FALSE, any free socket number is assigned dynamically and opened.
<b>Returns</b>	0 No error.  <code>slkErrOutOfSockets</code> No more sockets can be opened.
<b>Comments</b>	The communications library must already be initialized and opened (see <a href="#">SerOpen()</a> ). When finished using the socket, the caller must call <a href="#">SlkCloseSocket()</a> to free system resources allocated for the socket. For information about well-known static socket IDs, see <a href="#">The Serial Link Protocol</a> .

## SlkReceivePacket Function

<b>Purpose</b>	Receive and validate a packet for a particular socket or for any socket. Check for format and checksum errors.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkReceivePacket (UInt16 socket, Boolean andOtherSockets, SlkPktHeaderPtr headerP, void* bodyP, UInt16 bodySize, Int32 timeout)</code>
<b>Parameters</b>	 → <code>socket</code> The socket ID.  → <code>andOtherSockets</code> If TRUE, ignore destination in packet header.  ↔ <code>headerP</code> Pointer to the packet header buffer (size of <code>SlkPktHeaderType</code> ).  ↔ <code>bodyP</code> Pointer to the packet client data buffer.  → <code>bodySize</code> Size of the client data buffer (maximum client data size which can be accommodated).

→ *timeout*

Maximum number of system ticks to wait for beginning of a packet; -1 means wait forever.

**Returns** 0

No error.

`slkErrSocketNotOpen`

The socket was not open.

`slkErrTimeOut`

Timed out waiting for a packet.

`slkErrWrongDestSocket`

The packet being received had an unexpected destination.

`slkErrChecksum`

Invalid header checksum or packet CRC-16.

`slkErrBuffer`

Client data buffer was too small for packet's client data.

If `andOtherSockets` is `FALSE`, this routine returns with an error code unless it gets a packet for the specific socket.

If `andOtherSockets` is `TRUE`, this routine returns successfully if it sees any incoming packet from the communications library used by socket.

**Comments**

You may request to receive a packet for the passed socket ID only, or for any open socket which does not have a socket listener. The parameters also specify buffers for the packet header and client data, and a timeout. The timeout indicates how long the receiver should wait for a packet to begin arriving before timing out. If a packet is received for a socket with a registered socket listener, it will be dispatched via its socket listener procedure. On success, the packet header buffer and packet client data buffer is filled in with the actual size of the packet's client data in the packet header's `bodySize` field.

## SlkSendPacket Function

<b>Purpose</b>	Send a serial link packet via the serial output driver.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkSendPacket (SlkPktHeaderPtr headerP, SlkWriteDataPtr writeList)</code>
<b>Parameters</b>	<p><math>\leftrightarrow</math> <i>headerP</i> Pointer to the packet header structure with client information filled in (see Comments).</p> <p><math>\rightarrow</math> <i>writeList</i> List of packet client data blocks (see Comments).</p>
<b>Returns</b>	<p>0 No error.</p> <p><code>slkErrSocketNotOpen</code> The socket was not open.</p> <p><code>slkErrTimeOut</code> Handshake timeout.</p>
<b>Comments</b>	<p><code>SlkSendPacket</code> stuffs the signature, client data size, and the checksum fields of the packet header. The caller must fill in all other packet header fields. If the transaction ID field is set to 0 (zero), the serial link manager automatically generates and stuffs a new non-zero transaction ID. The array of <code>SlkWriteDataType</code> structures enables the caller to specify the client data part of the packet as a list of noncontiguous blocks. The end of list is indicated by an array element with the <code>size</code> field set to 0 (zero). This call blocks until the entire packet is sent out or until an error occurs.</p>

## SlkSetSocketListener Function

<b>Purpose</b>	Register a socket listener for a particular socket.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkSetSocketListener (UInt16 socket, SlkSocketListenPtr socketP)</code>
<b>Parameters</b>	<p><math>\rightarrow</math> <i>socket</i> Socket ID.</p>

	<code>→ socketP</code> Pointer to a <code>SlkSocketListenType</code> structure.
<b>Returns</b>	<code>0</code> No error.  <code>slkErrBadParam</code> Invalid parameter.  <code>slkErrSocketNotOpen</code> The socket was not open.
<b>Comments</b>	<p>Called by applications to set up a socket listener.</p> <p>Since the serial link manager does not make a copy of the <code>SlkSocketListenType</code> structure, but instead saves the passed pointer to it, the structure</p> <ul style="list-style-type: none"><li>• must <b>not</b> be an automatic variable (that is, local variable allocated on the stack)</li><li>• may be a global variable in an application</li><li>• may be a locked chunk allocated from the dynamic heap</li></ul> <p>The <code>SlkSocketListenType</code> structure specifies pointers to the socket listener procedure and the data buffers for dispatching packets destined for this socket. Pointers to two buffers must be specified: the packet header buffer (size of <code>SlkPktHeaderType</code>), and the packet body (client data) buffer. The packet body buffer must be large enough for the largest expected client data size. Both buffers may be application global variables or locked chunks allocated from the dynamic heap.</p> <p>The socket listener procedure is called when a valid packet is received for the socket. Pointers to the packet header buffer and the packet body buffer are passed as parameters to the socket listener procedure.</p> <hr/> <p><b>NOTE:</b> The application is responsible for freeing the <code>SlkSocketListenType</code> structure or the allocated buffers when the socket is closed. The serial link manager doesn't do it.</p> <hr/>
<b>Compatibility</b>	If <a href="#">5.0 New Feature Set</a> is present this function is unimplemented.

## SlkSocketPortID Function

<b>Purpose</b>	Get the port ID associated with a particular socket; for use with the new serial manager.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>ErrSlkSocketPortID (UInt16 socket,                       UInt16 * portIDP)</code>
<b>Parameters</b>	<p>→ <i>socket</i> The socket ID.</p> <p>↔ <i>portIDP</i> Pointer to location for returning the port ID.</p>
<b>Returns</b>	<p>0 No error.</p> <p><code>slkErrSocketNotOpen</code> The socket was not open.</p>
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set</a> is present.

## SlkSocketSetTimeout Function

<b>Purpose</b>	Set the interbyte packet receive-timeout for a particular socket.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>ErrSlkSocketSetTimeout (UInt16 socket,                           Int32 timeout)</code>
<b>Parameters</b>	<p>→ <i>socket</i> Socket ID.</p> <p>→ <i>timeout</i> Interbyte packet receive-timeout in system ticks.</p>
<b>Returns</b>	<p>0 No error.</p> <p><code>slkErrSocketNotOpen</code> The socket was not open.</p>

# Telephony Basic Services

---

This chapter provides reference material for the Telephony API, which you can use to interface with telephone systems and equipment. This chapter discusses the following topics:

- [Telephony Data Structures](#)
- [Telephony Constants](#)
- [Telephony Functions](#)
- [Feature Support Functions](#)

The header file `TelephonyMgr.h` declares the telephony manager API. The header file `TelephonyMgrType.h` declares the data structures that you use with the telephony manager API.

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Service Types

The telephony API organizes functions within sets called **service sets**. Each service set contains a related set of functions that may or may not be available on a particular mobile device or network. You can use the [TelIs<ServiceSet>Available\(\)](#) function to determine if a service set is supported in the current environment, and you can use the [TelIs<FunctionName>Supported\(\)](#) to determine if a specific function is supported in the current environment.

## Telephony Basic Services

### Telephony Service Types

---

The telephony API documentation has been split into several chapters. Each chapter covers one or more of the service sets, as shown in [Table 68.1](#)

**Table 68.1 Telephony service types**

Service prefix	Functionality	Chapter	Description
Tel	Basic	<a href="#">Chapter 68, "Telephony Basic Services."</a>	Basic functions that are always available.
TelCfg	Configuration	<a href="#">Chapter 69, "Telephony Security and Configuration."</a>	Allows configuration of the phone, including Short Message Services (SMS) configuration.
TelDtc	Data calls	<a href="#">Chapter 71, "Telephony Calls."</a>	Functions for handling data calls.
TelEmc	Emergency calls	<a href="#">Chapter 71, "Telephony Calls."</a>	Functions for handling emergency calls.
TelInf	Information	<a href="#">Chapter 68, "Telephony Basic Services."</a>	Functions for retrieving information about the phone.
TelNwk	Network	<a href="#">Chapter 70, "Telephony Network."</a>	Provides network oriented services, including authorization, signal level, search mode, and related operations.
TelOem	OEM	<a href="#">Chapter 68, "Telephony Basic Services."</a>	Provides OEMs with the ability to incorporate custom functionality.
TelPhb	Phone book	<a href="#">Chapter 73, "Telephony Phone Book."</a>	Functions for managing the phone book.

**Table 68.1 Telephony service types (*continued*)**

Service prefix	Functionality	Chapter	Description
TelPow	Power	<a href="#">Chapter 68, “Telephony Basic Services.”</a>	Provides access to power supply level.
TelSms	Short Message Service	<a href="#">Chapter 72, “Telephony SMS.”</a>	Addresses the SMS, including functions for reading, sending, replying to, and deleting short messages.
TelSnd	Sound	<a href="#">Chapter 68, “Telephony Basic Services.”</a>	Functions for playing key tones on and muting the phone.
TelSpc	Speech calls	<a href="#">Chapter 71, “Telephony Calls.”</a>	Function for handling voice calls, including dual tone modulated frequency (DTMF) sounds.
TelSty	Security	<a href="#">Chapter 69, “Telephony Security and Configuration.”</a>	Supports PIN code management for access to phone and Subscriber Identity Module (SIM) security-related features.

## Telephony Data Structures

This section describes the data structures used with the basic services portion of the telephony API.

### TelEventType Struct

**Purpose** The [TelGetEvent\(\)](#) and [TelGetTelephonyEvent\(\)](#) functions both return a `TelEventType` structure to provide information about a telephony-related event.

You call the [TelGetEvent\(\)](#) function to retrieve telephony and other events.

## Telephony Basic Services

### *TelEventType*

---

You call the [TelGetTelephonyEvent\(\)](#) function to retrieve only telephony events. This function does not consume non-telephony events.

**Prototype**

```
typedef struct _TelEventType
{
    eventsEnum    eType;
    Boolean        penDown;
    UInt8          tapCount;
    Int16          screenX;
    Int16          screenY;
    UInt16         functionId;
    UInt16         transId;
    MemPtr         *paramP;
    Err            returnCode;
} TelEventType
```

#### Field Descriptions

eType	One of the <a href="#">eventsEnum</a> constants. Specifies the type of the event.
penDown	true if the pen was down at the time of the event, and false if the pen was up.  Note that this field is not filled in for telephony events.
tapCount	The number of taps received at this location. This value is used mainly by text fields. When the user taps in a text field, two taps selects a word, and three taps selects the entire line.  Note that this field is not filled in for telephony events.

tapCount

The number of taps received at this location. This value is used mainly by text fields. When the user taps in a text field, two taps selects a word, and three taps selects the entire line.

Note that this field is not filled in for telephony events.

## Telephony Basic Services

### *TelCallStateType*

---

Note that the first five fields of the `TelEventType` structure are the same as the first five fields of the [EventType](#) structure, which is described in [Chapter 2, “Palm OS Events.”](#)

## TelCallStateType Struct

**Purpose** The [TelGetCallState\(\)](#) function uses the `TelCallState` structure to retrieve information about the current state of the connected phone.

**Prototype**

```
typedef struct _TelGetCallStateType
{
    UInt8    state;
    UInt8    callType;
    UInt8    callServiceType;
    UInt8    numberSize;
    Char     *number;
} TelGetCallStateType
```

### Field Descriptions

←	state	Filled in with one of the <a href="#">Telephone Call State Constants</a> , which indicates the current state of the telephone call.
←	callType	Filled in with one of the <a href="#">Telephone Call Type Constants</a> , which indicates the call type of the current telephone call.
←	callServiceType	Filled in with one of the <a href="#">Telephone Call Service Type Constants</a> , which indicates the call service type of the current telephone call.

↔      `numberSize`      The size of the number string buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer.

Upon return, this is the actual size of the string, including the null terminator character. If the number buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the data, and the function using this structure generates a `telErrBufferSize` error.

←      `number`      A buffer into which the telephone number string is stored.

When the structure describes an incoming telephone call, this is the incoming telephone number. When the structure describes an outgoing telephone call, this is the telephone number that has been called.

Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

## **TelInfGetformationType Struct**

**Purpose**      The [TelInfGetInformation\(\)](#) function uses the `TelInfGetInformationType` structure to retrieve information about the phone with which you are communicating.

**Prototype**

```
typedef struct _TelInfGetInformationType
{
    UInt8      infoType;
    UInt8      size;
    UInt8      *value;
} TelInfGetInformationType
```

## Telephony Basic Services

### *TelOemCallType*

---

#### Field Descriptions

→	infoType	The type of information to retrieve. This must be one of the <a href="#">Information Type Constants</a> .
↔	size	The size of the value buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer.  Upon return, this is the actual size of the buffer. If the value buffer is too small to contain all of the retrieved information, this field is assigned the entire length of the data, and the function using this structure generates a <code>telErrBufferSize</code> error.
←	value	A buffer into which the information is stored.

#### TelOemCallType Struct

**Purpose** You use the `TelOemCallType` to specify a [TelOemCall\(\)](#) function.

**Prototype**

```
typedef struct _TelOemCallType
{
    UInt32  OemID;
    UInt8   funcID;
    void     *paramP;
} TelOemCallType
```

#### Field Descriptions

→	OemID	The unique ID of the OEM function set.
→	funcID	The ID of the function within the OEM function set.
↔	paramP	A pointer to a parameter block that is passed to the OEM function. The OEM function might modify some of the fields in the parameter block.

## TelSendCommandStringType Struct

**Purpose** The [TelSendCommandString\(\)](#) function uses the TelSendCommandStringType structure to send a command string.

**Prototype**

```
typedef struct _TelSendCommandStringType
{
    Char      *commandString;
    Char      *resultString;
    UInt16    resultSize;
    UInt32    timeOut;
} TelSendCommandStringType
```

### Field Descriptions

- |   |               |  |
|---|---------------|--|
| → | commandString | The command string to send.  |
| ← | resultString  | The result string.   |
| ↔ | resultSize    | The size of the resultString string buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer. |

Upon return, this is the actual size of the string, including the null terminator character. If the resultString buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the data, and the function using this structure generates a telErrBufferSize error.

- |   |         |   |
|---|---------|---|
| → | timeOut | The number of milliseconds before timing out. |
|---|---------|---|

## TelSndPlayKeyToneType Struct

**Purpose** The [TelSndPlayKeyTone\(\)](#) function uses the TelSndPlayKeyToneType structure to specify a key tone.

**Prototype**

```
typedef struct _TelSndPlayKeyToneType
{
    UInt8      keycode;
    UInt8      type;
```

## Telephony Basic Services

### Telephony Constants

---

```
} TelSndPlayKeyToneType
```

#### Field Descriptions

- `keycode`              The keycode of the key tone to play. This must be one of the [Keycode Constants](#).
- `type`                      The tone type. This must be one of the [Key Sound Type Constants](#).

## Telephony Constants

This section describes the data structures used with the basic services portion of the telephony API, which include the following constant types:

- [Battery Status Constants](#)
- [Telephone Call State Constants](#)
- [Telephone Call Type Constants](#)
- [Telephone Call Service Type Constants](#)
- [Error Code Constants](#)
- [Information Type Constants](#)
- [Keycode Constants](#)
- [Key Sound Type Constants](#)
- [Message Identifier Constants](#)
- [Service Set Constants](#)

### Battery Status Constants

The battery status constants provide information about the phone's battery.

Constant	Value	Description
<code>kTelPowBatteryPowered</code>	0	The phone is powered by a battery.
<code>kTelPowBatteryNotPowered</code>	1	The phone has a battery connected to it, but is not using that battery.

Constant	Value	Description
kTelPowNobattery	2	The phone does not have a battery connected to it.
kTelPowBatteryFault	3	The phone has a recognized power fault; calls are currently inhibited.

## Telephone Call State Constants

The [TelCallStateType](#) structure uses the telephone call state constants to encode the current state of the connected telephone call.

Constant	Value	Description
kTelCallIdle	0x00	The connection is idle.
kTelCallConnecting	0x01	A telephone call is currently connecting.
kTelCallConnected	0x02	A telephone call is currently connected.
kTelCallRedial	0x03	A telephone call is being re-dialed.
kTelCallIncoming	0x04	A telephone call is currently incoming.
kTelCallIncomingAck	0x05	An incoming telephone call is currently being acknowledged.
kTelCallDisconnecting	0x06	A telephone call is being disconnected.

## Telephone Call Type Constants

The [TelCallStateType](#) structure uses the telephone call type constants to encode the type of the current telephone call.

## Telephony Basic Services

### Telephone Call Service Type Constants

---

Constant	Value	Description
kTelCallTypeOutgoing	0x00	An outgoing telephone call.
kTelCallTypeIncoming	0x01	An incoming telephone call.

## Telephone Call Service Type Constants

The [TelCallStateType](#) structure uses the telephone call service type constants to encode the service type of the current telephone call.

Constant	Value	Description
kTelCallServiceVoice	0x00	A voice telephone call.
kTelCallServiceData	0x01	A data telephone call.

## Error Code Constants

The telephony manager functions return the error code constants shown in the following table to indicate their status.

Constant	Description
telErrBufferSize	One of the buffers used to retrieve data is too small.
telErrCodingScheme	The coding scheme specified for the short message is not valid.
telErrCommandFailed	The specified command could not be performed by the phone. Check the phone driver.
telErrEntryNotFound	The specified entry was not found.
telErrFeatureNotSupported	The specified feature is not supported by the phone or network.
telErrGenericDrvNotFound	The generic driver could not be found.

<b>Constant</b>	<b>Description</b>
<code>telErrInvalidAppId</code>	The specified application ID is not valid.
<code>telErrInvalidDial</code>	The dial string contains an invalid character.
<code>telErrInvalidIndex</code>	The index specified for accessing a value in storage is incorrect.
<code>telErrInvalidParameter</code>	A parameter is not valid.
<code>telErrInvalidString</code>	The text string contains an invalid character.
<code>telErrLibStillInUse</code>	The shared lib is currently being used by another application. Do not unload it!
<code>telErrMemAllocation</code>	A memory allocation error occurred.
<code>telErrMsgAllocation</code>	The telephony messages pool is empty; a message could not be allocated.
<code>telErrNetworkTimeOut</code>	The network did not reply within the standard time delay amount.
<code>telErrNoNetwork</code>	There is no network available.
<code>telErrNoSIMInserted</code>	The SIM card is not inserted.
<code>telErrNoSpecificDrv</code>	A specific driver was not specified.
<code>telErrNotInstalled</code>	The shared library could not be installed.
<code>telErrPassword</code>	The password is not correct.
<code>telErrPhoneCodeRequired</code>	A phone code is required.
<code>telErrPhoneComm</code>	The communication link with the phone is down.
<code>telErrPhoneMemAllocation</code>	The phone's memory is full.
<code>telErrPhoneMemFailure</code>	The phone encountered a memory error.
<code>telErrPhoneNumber</code>	One of the following errors has occurred: the phone number is wrong, the SMS center is not valid, or the receiver phone number is wrong for the SMS.

## Telephony Basic Services

### *Error Code Constants*

---

Constant	Description
<code>telErrPhoneReply</code>	The phone reply syntax is incorrect. Check the phone driver.
<code>telErrPhoneToSIMPINRequired</code>	A phone 2 SIM PIN code is required
<code>telErrPIN2Required</code>	A PIN2 code is required.
<code>telErrPINRequired</code>	A PIN code is required.
<code>telErrPUK2Required</code>	A PUK2 code is required.
<code>telErrPUKRequired</code>	A PUK code is required.
<code>telErrResultBusyResource</code>	A resource is busy.
<code>telErrResultTimeOut</code>	A time-out was reached.
<code>telErrResultUserCancel</code>	The user cancelled the action.
<code>telErrSecurity</code>	Access to the phone was not granted.
<code>telErrSettings</code>	The telephony settings are not valid; this is due to 1) the Phone Panel preferences do not exist, or 2) the Telephony Profile is not correctly set.
<code>telErrSIMBusy</code>	The SIM could not reply.
<code>telErrSIMFailure</code>	The SIM is not working properly.
<code>telErrSIMWrong</code>	The SIM is not accepted by the phone.
<code>telErrSpcCallError</code>	The voice telephone call encountered an error.
<code>telErrSpcLineIsBusy</code>	The voice telephone call failed.
<code>telErrSpcLineIsReleased</code>	The voice telephone call has been released.
<code>telErrSpecificDrvNotFound</code>	The specified driver could not be found.
<code>telErrTooManyApps</code>	The applications table is full.
<code>telErrTTaskNotFound</code>	The Telephony Task could not be found.
<code>telErrTTaskNotRunning</code>	The Telephony Task is not running.

Constant	Description
telErrUnavailableValue	The requested value can not be retrieved at the specified time. This is usually due to a <code>TelSpcGetCallerNumber</code> request when there is no active line.
telErrUnknown	An unknown telephony manager error occurred.
telErrValidityPeriod	The validity period specified for the short message is not valid.
telErrValueStale	The information could not be retrieved; a copy of the most recently retrieved value has been returned instead.
telErrVersion	The shared library version does not match the version associated with the application.

## Information Type Constants

The [TelInfGetformationType](#) structure uses the information type constants to encode the type of information to retrieve about the phone.

Constant	Value	Description
kTelInfPhoneBrand	0	The brand name of the phone.
kTelInfPhoneModel	1	The model number of the phone.
kTelInfPhoneRevision	2	The revision number of the phone.

## Keycode Constants

The [TelSndPlayKeyToneType](#) structure uses the keycode constants to specify the key tone to play.

## Telephony Basic Services

### Key Sound Type Constants

---

Constant	Value	Description
kTel0Key	0x00	The 0 key on the phone keypad.
kTel1Key	0x01	The 1 key on the phone keypad.
kTel2Key	0x02	The 2 key on the phone keypad.
kTel3Key	0x03	The 3 key on the phone keypad.
kTel4Key	0x04	The 4 key on the phone keypad.
kTel5Key	0x05	The 5 key on the phone keypad.
kTel6Key	0x06	The 6 key on the phone keypad.
kTel7Key	0x07	The 7 key on the phone keypad.
kTel8Key	0x08	The 8 key on the phone keypad.
kTel9Key	0x09	The 9 key on the phone keypad.
kTelPoundKey	0x23	The POUND(#) key on the phone keypad.
kTelStarKey	0x2A	The STAR(*) key on the phone keypad.
kTelSendKey	0x45	The SEND key on the phone keypad.
kTelEndKey	0x46	The END key on the phone keypad.
kTelClrKey	0x47	The CLEAR key on the phone keypad.
kTelSaveKey	0x48	The SAVE key on the phone keypad.

## Key Sound Type Constants

The [TelSndPlayKeyToneType](#) structure uses the key sound type constants to specify how the tone is played.

Constant	Value	Description
kTelSndSingleTone	0x00	Play the key sound as a single tone.
kTelSndMultiTones	0x01	Play the key sound as a multiple tones.

## Message Identifier Constants

The message identifier constants are used with asynchronous calls to identify which telephony function is being or has been called. The `TelMessages` enumeration defines a constant for each function name.

Each message identifier constant has the form:

`kfunctionNameMessage`

where *functionName* is replaced by a function name.

The following table shows examples of message identifier constants. For a complete list, see the `TelephonyMgr.h` file.

Constant	Function
kTelGetCallStateMessage	<a href="#"><code>TelGetCallState()</code></a>
kTelNwkSelectNetworkMessage	<a href="#"><code>TelNwkSelectNetwork()</code></a>
kTelSmsReadMessageMessage	<a href="#"><code>TelSmsReadMessage()</code></a>

## Service Set Constants

The service set constants specify a set of API services.

Constant	Value	Description
kTelNwkServiceId	0	The network service set.
kTelStyServiceId	1	The security service set.

## Telephony Basic Services

### Telephony Functions

---

Constant	Value	Description
kTelPowServiceId	2	The power service set.
kTelCfgServiceId	3	The configuration service set.
kTelSmsServiceId	4	The short message service set.
kTelEmcServiceId	5	The emergency telephone call service set.
kTelSpcServiceId	6	The speech telephone call service set.
kTelDtcServiceId	7	The data telephone call service set.
kTelPhbServiceId	8	The phone book service set.
kTelOemServiceId	9	The OEM service set.
kTelSndServiceId	10	The sound service set.
kTelInfServiceId	11	The information service set.

## Telephony Functions

This section describes the functions used with the basic services portion of the telephony API.

### TelCancel Function

<b>Purpose</b>	Cancels an asynchronous function call.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelCancel(UInt16 iRefnum, TelAppID iAppId,                UInt16 iTransId, UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p>

---

	<p>→ <i>iTransId</i></p> <p>The transaction ID associated with the function that you are cancelling.</p> <p>↔ <i>ioTransIdP</i></p> <p>Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	<p>Returns <code>errNone</code> if the function call was successfully cancelled.</p> <p>Returns the <code>telErrCommandFailed</code> error code if the function call could not be cancelled.</p>								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelUrqCancelMessage</code></td></tr> <tr> <td><code>paramId</code></td><td>Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.</td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>functionId</code>	<code>kTelUrqCancelMessage</code>	<code>paramId</code>	Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>functionId</code>	<code>kTelUrqCancelMessage</code>								
<code>paramId</code>	Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.								
<b>Comments</b>	<p>This function cancels a pending asynchronous function call. You can cancel any asynchronous call except for an asynchronous call to the <code>TelCancel</code> function.</p> <p>The function call that is cancelled returns the <code>telErrUserCancel</code> error code.</p>								
<b>Compatibility</b>	<p>Implemented only if <a href="#">4.0 New Feature Set</a> is present.</p>								

## TelClose Function

<b>Purpose</b>	Close the shared library.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelClose(UInt16 iRefnum, TelAppID iAppId)
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p>
<b>Returns</b>	Returns an error code, or error none if the library was successfully closed. If the library is currently being used by another application, this function returns the telErrLibStillInUse error code.
<b>Comments</b>	<p>Call this function when you are done with the telephony manager. You can only use this function synchronously.</p> <p>If no other application is using the telephony manager, this function stops the Telephony task and releases any resources used by the telephony manager.</p>
<b>See Also</b>	<a href="#">TelOpen()</a>

## TelClosePhoneConnection Function

<b>Purpose</b>	Closes down communications with the connected phone.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelClosePhoneConnection(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p>

---

	<p>↔ <i>ioTransIdP</i></p> <p>Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>A NULL pointer.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelUrqClosePhoneConnectionMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	A NULL pointer.	<code>functionId</code>	<code>kTelUrqClosePhoneConnectionMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	A NULL pointer.								
<code>functionId</code>	<code>kTelUrqClosePhoneConnectionMessage</code>								
<b>Comments</b>	Call this function when you have finished communications with the phone and are ready to disconnect from it.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelOpenPhoneConnection()</a>								

## TelGetCallState Function

<b>Purpose</b>	Retrieves the current telephone call state information.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelGetCallState(UInt16 iRefnum,                     TelAppID iAppId,                     TelGetCallStateType *ioParamP,                     UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p>

## Telephony Basic Services

### *TelGetCallState*

---

↔ *ioParamP*

A pointer to a [TelCallStateType](#) structure that describes the state of the current telephone call.

On input, the `numberSize` field of this structure specifies the allocated size of the number buffer. Upon return, the `numberSize` field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelCallStateType</a> structure passed to this function in the <code>ioCallState</code> parameter.
<code>functionId</code>	<code>kTelGetCallStateMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

This function retrieves information about the current telephone call state of the connection with the phone, and stores that information into the supplied [TelCallStateType](#) structure.

The current incoming or outgoing telephone call number is stored into the `number` field of the [TelCallStateType](#) structure referenced by `ioCallStateP`. If the `number` field buffer is too

small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `numberSize` field of the structure is always updated to contain the actual size of the complete telephone number.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcAcceptCall\(\)](#), [TelSpcCallNumber\(\)](#)

## TelGetEvent Function

**Purpose** Retrieves events for applications that use the telephony manager.

**Declared In** `TelephonyMgr.h`

**Prototype** `void TelGetEvent(UInt16 iRefnum, TelAppID iAppId, EventPtr oEventP, Int32 iTimeout)`

**Parameters** → *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

← *oEventP*

A pointer to a [TelEventType](#) structure. Upon return, the structure contains the event information, which you should use as described in the Comments section.

→ *iTimeout*

Maximum number of ticks to wait before an event is returned (`evtWaitForever` means wait indefinitely).

**Returns** Returns nothing.

**Comments** This function retrieves both telephony and standard Palm OS® events. You must call this function to retrieve events in any application that is running in the UI task and using the telephony manager.

Upon return from this function, you need to test the type of the event by examining the `oEventP->type` field. If the event type is a telephony event, then you need to cast the pointer as follows to access the fields:

## Telephony Basic Services

### *TelGetTelephonyEvent*

---

---

```
TelEventType *telEventP = (TelEventType *)oEventP;
```

---

This function calls both the [EvtGetEvent\(\)](#) and [TelGetTelephonyEvent\(\)](#) functions to retrieve the next event for your application.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [EvtGetEvent\(\)](#), [TelGetTelephonyEvent\(\)](#)

## TelGetTelephonyEvent Function

**Purpose** Retrieves telephony events only.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
void TelGetTelephonyEvent(UInt16 iRefnum,
                          TelAppID iAppID, EventPtr oEventP,
                          Int32 iTimeout)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppID*  
The telephone application attachment identifier for your application.
- ← *oEventP*  
A pointer to a [TelEventType](#) structure. Upon return, the structure contains the event information.
- *iTimeout*  
Maximum number of ticks to wait before an event is returned (evtWaitForever means wait indefinitely).

**Returns** Returns nothing.

**Comments** Use this function instead of the [TelGetEvent\(\)](#) function when you only want to process telephony events.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [EvtGetEvent\(\)](#), [TelGetEvent\(\)](#)

## TelInfGetInformation Function

<b>Purpose</b>	Retrieve brand, model, and revision information for the phone.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelInfGetInformation(UInt16 iRefnum,                         TelAppID iAppId,                         TelInfGetInformationType *ioParamP,                         UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i>  A pointer to a <a href="#">TelInfGetInformationType</a> structure.  On input, the <code>infoType</code> field of the structure contains the type of information that you want retrieved. The <code>size</code> field of this structure specifies the allocated size of the value buffer. Upon return, the <code>size</code> field specifies the actual size of the information that was retrieved, even if it was truncated to fit into the buffer.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <p><code>returnCode</code>      <code>errNone</code> upon success or an error code upon failure.</p> <p><code>transId</code>          The transaction ID of the operation.</p>

## Telephony Basic Services

### *TelIsCfgServiceAvailable*

---

paramP	Points to the <a href="#">TelInfGetformationType</a> structure passed to this function in the ioInfoP parameter.
functionId	kTelInfGetInformationMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

<b>Comments</b>	<p>Call this function to retrieve information about the currently connected phone.</p> <p>The retrieved information is stored into the value field of the <a href="#">TelInfGetformationType</a> referenced by ioInfoP structure. If the value field buffer is too small to contain the complete information, the value is truncated and this function returns the telErrBufferSize error. The size field of the structure is always updated to contain the actual size of the retrieved information.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsInfServiceAvailable()</a> macro.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.

## TelIsCfgServiceAvailable Macro

<b>Purpose</b>	Determines if the configuration service set is available in the current environment.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>#define TelIsCfgServiceAvailable (iRefnum,                                 iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p>

---

	<p>↔ <i>ioTransIdP</i></p> <p>Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td><code>kTelCfgServiceId</code></td></tr> <tr> <td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelCfgServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelCfgServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	<p>You need to call this macro before calling any function in the configuration service set, which is the family of functions that begin with the <code>TelCfg</code> prefix.</p> <p>The configuration service set functions are documented in <a href="#">Chapter 72, “Telephony SMS.”</a></p>								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>								

## TellsDtcServiceAvailable Macro

<b>Purpose</b>	Determines if the data calls service set is available in the current environment.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>#define TelIsDtcServiceAvailable (iRefnum,                                 iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i></p> <p>The telephony manager library reference number.</p>

## Telephony Basic Services

### *TelIsDtcServiceAvailable*

---

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the service set is available, or an error code if not.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` if the service set is available, or an error code if not.

`transId`          The transaction ID of the operation.

`paramP`           `kTelDtcServiceId`

`functionId`      `kTelUrqIsServiceAvailableMessage`

#### **Comments**

You need to call this macro before calling any function in the data calls service set, which is the family of functions that begin with the `TelDtc` prefix.

The data calls service set functions are documented in [Chapter 71](#), “[Telephony Calls](#).”

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelIs<FunctionName>Supported\(\)](#)

## TellsEmcServiceAvailable Macro

<b>Purpose</b>	Determines if the emergency calls service set is available in the current environment.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>#define TellsEmcServiceAvailable (iRefnum,                                 iAppId, ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td><code>kTelEmcServiceId</code></td></tr> <tr> <td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelEmcServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelEmcServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	<p>You need to call this macro before calling any function in the emergency calls service set, which is the family of functions that begin with the <code>TelEmc</code> prefix.</p> <p>The emergency calls service set functions are documented in <a href="#">Chapter 71, “Telephony Calls.”</a></p>								

## Telephony Basic Services

### *TelIsInfServiceAvailable*

---

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelIs<FunctionName>Supported\(\)](#)

## TelIsInfServiceAvailable Macro

**Purpose**            Determines if the information service set is available in the current environment.

**Declared In**      `TelephonyMgr.h`

**Prototype**        `#define TelIsInfServiceAvailable (iRefnum,  
                                      iAppId, ioTransIdP)`

**Parameters**       `→ iRefnum`

                      The telephony manager library reference number.

`→ iAppId`

                      The telephone application attachment identifier for your application.

`↔ ioTransIdP`

                      Set the value of this parameter to NULL to cause the function to execute synchronously.

                      If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result**    The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`            `errNone` if the service set is available, or an error code if not.

`transId`                The transaction ID of the operation.

`paramP`                `kTelInfServiceId`

`functionId`            `kTelUrqIsServiceAvailableMessage`

---

<b>Comments</b>	<p>You need to call this macro before calling any function in the information service set, which is the family of functions that begin with the <code>TelInf</code> prefix.</p> <p>The information service set functions are documented in this chapter.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>

## TellsNwkServiceAvailable Macro

<b>Purpose</b>	Determines if the network service set is available in the current environment.				
<b>Declared In</b>	TelephonyMgr.h				
<b>Prototype</b>	<pre>#define TelIsNwkServiceAvailable (iRefnum,                                 iAppId, ioTransIdP)</pre>				
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>				
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.				
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> </table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.				
<code>transId</code>	The transaction ID of the operation.				

## Telephony Basic Services

### *TelIsOemServiceAvailable*

---

	<code>paramP</code>	<code>kTelNwkServiceId</code>
	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<b>Comments</b>	<p>You need to call this macro before calling any function in the network service set, which is the family of functions that begin with the <code>TelNwk</code> prefix.</p> <p>The network service set functions are documented in <a href="#">Chapter 70, “Telephony Network.”</a></p>	
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.	
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>	

## TellsOemServiceAvailable Macro

<b>Purpose</b>	Determines if the OEM service set is available in the current environment.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>#define TelIsOemServiceAvailable     (iRefnum, iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.</p> <p>If this parameter is not <code>NULL</code>, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:

---

	returnCode	errNone if the service set is available, or an error code if not.
	transId	The transaction ID of the operation.
	paramP	kTelOemServiceId
	functionId	kTelUrqIsServiceAvailableMessage
<b>Comments</b>	<p>You need to call this macro before calling any function in the OEM service set, which is the family of functions that begin with the TelOem prefix.</p> <p>The OEM service set functions are documented in this chapter.</p>	
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.	
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>	

## TellsPhbServiceAvailable Macro

<b>Purpose</b>	Determines if the phone book service set is available in the current environment.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>#define TelIsPhbServiceAvailable       (iRefnum, iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns errNone if the service set is available, or an error code if not.

## Telephony Basic Services

### *TellIsPhoneConnected*

---

<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td><code>kTelPhbServiceId</code></td></tr><tr><td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelPhbServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelPhbServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	<p>You need to call this macro before calling any function in the phone book service set, which is the family of functions that begin with the <code>TelPhb</code> prefix.</p> <p>The phone book service set functions are documented in <a href="#">Chapter 73</a>, “<a href="#">Telephony Phone Book</a>.”</p>								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>								

## TellsPhoneConnected Function

<b>Purpose</b>	Determines if a phone is connected.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>Err TelIsPhoneConnected(UInt16 iRefnum,                         TelAppID iAppId, UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.</p> <p>If this parameter is not <code>NULL</code>, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>

<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>A NULL pointer.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelUrqIsPhoneConnectedMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	A NULL pointer.	<code>functionId</code>	<code>kTelUrqIsPhoneConnectedMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	A NULL pointer.								
<code>functionId</code>	<code>kTelUrqIsPhoneConnectedMessage</code>								
<b>Comments</b>	Call this function to determine if there is currently a phone connected.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								

## TellIsPowServiceAvailable Macro

<b>Purpose</b>	Determines if the power services set is available in the current environment.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>#define TellIsPowServiceAvailable     (iRefnum, iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>

## Telephony Basic Services

### *TellSmsServiceAvailable*

---

<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:  <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td><code>kTelPowServiceId</code></td></tr><tr><td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelPowServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelPowServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	<p>You need to call this macro before calling any function in the power service set, which is the family of functions that begin with the <code>TelPow</code> prefix.</p> <p>The power service set functions are documented in this chapter.</p>								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported()</a>								

## TellSmsServiceAvailable Macro

<b>Purpose</b>	Determines if the Short Message Service (SMS) service set is available in the current environment.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>#define TelIsSmsServiceAvailable     (iRefnum, iAppId, ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.</p> <p>If this parameter is not <code>NULL</code>, the call executes asynchronously. Upon return from this function, this points</p>

to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` if the service set is available, or an error code if not.

`transId`          The transaction ID of the operation.

`paramP`          `kTelSmsServiceId`

`functionId`      `kTelUrqIsServiceAvailableMessage`

**Comments**

You need to call this macro before calling any function in the SMS service set, which is the family of functions that begin with the `TelSms` prefix.

The SMS service set functions are documented in [Chapter 72](#), “[Telephony SMS](#).”

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelIs<FunctionName>Supported\(\)](#)

## TelIsSndServiceAvailable Macro

**Purpose**

Determines if the sound service set is available in the current environment.

**Declared In**

`TelephonyMgr.h`

**Prototype**

```
#define TelIsSndServiceAvailable
    (iRefnum, iAppId, ioTransIdP)
```

**Parameters**

→ *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

## Telephony Basic Services

### *TelIsSpcServiceAvailable*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` if the service set is available, or an error code if not.

`transId`          The transaction ID of the operation.

`paramP`          `kTelSndServiceId`

`functionId`      `kTelUrqIsServiceAvailableMessage`

**Comments** You need to call this macro before calling any function in the sound service set, which is the family of functions that begin with the `TelSnd` prefix.

The sound service set functions are documented in this chapter.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported\(\)](#)

## TellsSpcServiceAvailable Macro

**Purpose** Determines if the speech telephone call service set is available in the current environment.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
#define TelIsSpcServiceAvailable  
    (iRefnum, iAppId, ioTransIdP)
```

**Parameters** → *iRefnum*  
The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	<code>kTelSpcServiceId</code>
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>

**Comments**

You need to call this macro before calling any function in the speech telephone call service set, which is the family of functions that begin with the `TelSpc` prefix.

The speech telephone call service set functions are documented in [Chapter 71](#), “[Telephony Calls](#).”

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelIs<FunctionName>Supported\(\)](#)

## TellStyServiceAvailable Macro

<b>Purpose</b>	Determines if the security service set is available in the current environment.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>#define TellStyServiceAvailable     (iRefnum, iAppId, ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td><code>kTelStyServiceId</code></td></tr><tr><td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelStyServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelStyServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	<p>You need to call this macro before calling any function in the security service set, which is the family of functions that begin with the <code>TelSty</code> prefix.</p> <p>The security service set functions are documented in <a href="#">Chapter 70</a>, “<a href="#">Telephony Network</a>.”</p>								

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**            [TelIs<FunctionName>Supported\(\)](#)

## TelMatchPhoneDriver Function

**Purpose**              Determines if the currently selected driver matches the connected phone.

**Declared In**        `TelephonyMgr.h`

**Prototype**          `Err TelMatchPhoneDriver(UInt16 iRefnum,  
                                  TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**         $\rightarrow$  *iRefnum*  
                              The telephony manager library reference number.

$\rightarrow$  *iAppId*  
                              The telephone application attachment identifier for your application.

$\leftrightarrow$  *ioTransIdP*  
                              Set the value of this parameter to NULL to cause the function to execute synchronously.

                             If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**      Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**    The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	A NULL pointer.
<code>functionId</code>	<code>kTelUrqMatchPhoneDriverMessage</code>

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

## TelOemCall Function

<b>Purpose</b>	Pass a call to an OEM function.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelOemCall(UInt16 iRefnum, TelAppID iAppId,                TelOemCallType *ioParamP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i> A pointer to a <a href="#">TelOemCallType</a> structure that contains information about the OEM function call.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td><code>transID</code></td><td>matches the output value of the <code>ioTransIdP</code> parameter</td></tr><tr><td><code>functionId</code></td><td>matches the function ID in the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter</td></tr><tr><td><code>paramId</code></td><td>points to the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter</td></tr></table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transID</code>	matches the output value of the <code>ioTransIdP</code> parameter	<code>functionId</code>	matches the function ID in the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter	<code>paramId</code>	points to the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transID</code>	matches the output value of the <code>ioTransIdP</code> parameter								
<code>functionId</code>	matches the function ID in the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter								
<code>paramId</code>	points to the <a href="#">TelOemCallType</a> structure passed to this function in the <code>ioParamP</code> parameter								

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

<b>Comments</b>	<p>Call this function to send a request to an OEM function. The calling function and the OEM function are responsible for coordinating the parameter block that is passed in the <a href="#">TelOemCallType</a> structure.</p> <p>Before using this function, you should verify that it is available by calling the <a href="#">TelIsOemServiceAvailable()</a> macro.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.

## TelOpen Function

<b>Purpose</b>	Open the telephony manager API to initialize telephony services and launch the telephony task.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>Err TelOpen(UInt16 iRefnum, UInt32 iVersnum,              TelAppID *oAppIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iVersnum</i> The version number of the shared library for which your application was developed.</p> <p>← <i>oAppIdP</i> A pointer to an application ID value. Upon return, this is the application ID that you supply as a parameter to the any other telephony functions that you call.</p>
<b>Returns</b>	<p>Returns <code>errNone</code> if the function was successful or returns an error code if not successful. The following errors can occur:</p> <ul style="list-style-type: none"> <li>the telephony task could not be found (<code>telErrTTaskNotFound</code>)</li> <li>the telephony task could not be launched (<code>telErrTTaskNotRunning</code>)</li> <li>the phone driver could not be found</li> </ul>

## Telephony Basic Services

### *TelOpenPhoneConnection*

---

- the shared library version is not valid

**Comments** You can only call this function synchronously. You must call this function before calling any other telephony manager functions.

You can specify the current version of the shared library by using the `kTelMgrVersion` constant as the value of the `iVersnum` parameter.

---

**IMPORTANT:** The shared library version number differs depending on which version of Palm OS you are targeting. This means that you may need to change how the `kTelMgrVersion` constant is constructed. If you are targeting Palm OS version 4.2, the minor version is 1 and the fix level is 0. For Palm OS 5, the minor version number is 0 and the fix level is 3. In `TelMgr.h`, make sure that the appropriate values of `kTelMgrVersionMinor` and `kTelMgrVersionFix` are un-commented, and that the values that don't apply are commented out.

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelClose\(\)](#)

## TelOpenPhoneConnection Function

**Purpose** Open communications with the connected phone.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelOpenPhoneConnection(UInt16 iRefnum,
                             TelAppID iAppId, UInt16 *ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`          A NULL pointer.

`functionId`      `kTelUrqOpenPhoneConnectionMessage`

**Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

**See Also**

[TelClosePhoneConnection\(\)](#)

## TelPowGetBatteryStatus Function

**Purpose**

Retrieves the status of the phone's battery.

**Declared In**

`TelephonyMgr.h`

**Prototype**

```
Err TelPowGetBatteryStatus(UInt16 iRefnum,
    TelAppID iAppId, UInt8 *oStatusP,
    UInt16 *ioTransIdP)
```

**Parameters**

→ *iRefnum*

The telephony manager library reference number.

→ *iAppId*

The telephone application attachment identifier for your application.

## Telephony Basic Services

### *TelPowGetBatteryStatus*

---

← *oStatusP*

A pointer to an unsigned byte value. Upon return, this is the battery status value, which is one of the [Battery Status Constants](#).

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oStatusP</code> parameter.
<code>functionId</code>	<code>kTelPowBatteryStatusMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oStatusP` remains in memory until the asynchronous call completes.

---

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelPowGetPowerLevel\(\)](#)

## TelPowGetPowerLevel Function

<b>Purpose</b>	Retrieve the current level of the phone battery, as a percentage value.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelPowGetPowerLevel (UInt16 iRefnum,                         TelAppID iAppId, UInt8 *oPowerP,                         UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>← <i>oPowerP</i>  A pointer to an unsigned byte value. Upon return, this is the battery percentage value.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.   If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelPowGetPowerLevelMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.	<code>functionId</code>	<code>kTelPowGetPowerLevelMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.								
<code>functionId</code>	<code>kTelPowGetPowerLevelMessage</code>								

## Telephony Basic Services

### *TelPowSetPhonePower*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oPowerP` remains in memory until the asynchronous call completes.

---

- Comments** The returned percentage value is an integer value between 0 and 100.
- Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable\(\)](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [TelPowGetBatteryStatus\(\)](#)

## TelPowSetPhonePower Function

- Purpose** Turns the phone on or off.
- Declared In** `TelephonyMgr.h`
- Prototype**

```
Err TelPowSetPhonePower(UInt16 iRefnum,
                          TelAppID iAppId, Boolean iPowerOn)
```
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - *iPowerOn*  
Set to `true` to turn the phone on, and set to `false` to turn the phone off.
- Returns** Returns `errNone` if the function was successful and an error code if not.
- Comments** This function can only be called synchronously.
- Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable\(\)](#) macro.
- This function corresponds to the `kTelPowSetPhonePowerMessage` function ID value.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelSendCommandString Function

<b>Purpose</b>	Sends a command string to the phone or to the network.				
<b>Declared In</b>	TelephonyMgr.h				
<b>Prototype</b>	<pre>Err TelSendCommandString(UInt16 iRefnum,                           TelAppID iAppId,                           TelSendCommandStringType *ioParamP,                           UInt16 *ioTransIdP)</pre>				
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i>  A pointer to a command string structure of type <a href="#">TelSendCommandStringType</a>.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.   If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>				
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.				
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.				
<code>transId</code>	The transaction ID of the operation.				

## Telephony Basic Services

### *TelSndMute*

---

paramP	Points to the <a href="#">TelSendCommandStringType</a> structure passed to this function in the ioParam parameter.
functionId	Matches the function ID in the <a href="#">TelOemCallType</a> referenced by the ioParamP structure.

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelSndMute Function

<b>Purpose</b>	Mute or un-mute an active telephone call.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelSndMute(UINT16 iRefnum, TelAppID iAppId, Boolean iMuteOn, UINT16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>→ <i>iMuteOn</i> Set to true to mute the telephone call, or set to false to unmute the telephone call.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>

<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table border="0" style="margin-left: 20px;"> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the Boolean value passed to this function in the <code>iMuteOn</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelSndMuteMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the Boolean value passed to this function in the <code>iMuteOn</code> parameter.	<code>functionId</code>	<code>kTelSndMuteMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the Boolean value passed to this function in the <code>iMuteOn</code> parameter.								
<code>functionId</code>	<code>kTelSndMuteMessage</code>								
<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsSndServiceAvailable()</a> macro.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelSndPlayKeyTone()</a>								

## TelSndPlayKeyTone Function

<b>Purpose</b>	Play a keytone sound on the phone.
<b>Declared In</b>	<code>TelephonyMgr.h</code>
<b>Prototype</b>	<pre>Err TelSndPlayKeyTone (UInt16 iRefnum,                        TelAppID iAppId,                        TelSndPlayKeyToneType *iParamP,                        UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i>            The telephony manager library reference number.</p> <p>→ <i>iAppId</i>            The telephone application attachment identifier for your application.</p> <p>→ <i>iParamP</i>            A pointer to a <a href="#">TelSndPlayKeyToneType</a> structure that describes the tone to play.</p>

## Telephony Basic Services

### *TelSndPlayKeyTone*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelSndPlayKeyToneType](#) structure passed to this function in the `iKeyToneP` parameter.

`functionId`      `kTelSndPlayKeyTone`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsSndServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelSndStopKeyTone\(\)](#)

## TelSndStopKeyTone Function

<b>Purpose</b>	Stop the playing of a keytone sound on the phone.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	Err TelSndStopKeyTone (UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns errNone if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr> <tr> <td>transId</td><td>The transaction ID of the operation.</td></tr> <tr> <td>paramP</td><td>A NULL pointer.</td></tr> <tr> <td>functionId</td><td>kTelSndStopKeyToneMessage</td></tr> </table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	kTelSndStopKeyToneMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	kTelSndStopKeyToneMessage								
<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsSndServiceAvailable()</a> macro.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelSndPlayKeyTone()</a>								

## Feature Support Functions

This section describes the functions that you can call to determine if a specific feature or function is supported in the current operating environment.

### Tells<FunctionName>Supported Macros

<b>Purpose</b>	Determines if the specified function is supported.				
<b>Declared In</b>	TelephonyMgr.h				
<b>Prototype</b>	<pre>#define TelIs&lt;FunctionName&gt;Supported     (iRefnum, iAppId, ioTransIdP)</pre>				
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>				
<b>Synchronous Result</b>	Returns <code>errNone</code> if the specified function is supported.				
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the specified function is supported, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the specified function is supported, or an error code if not.	<code>transId</code>	The transaction ID of the operation.
<code>returnCode</code>	<code>errNone</code> if the specified function is supported, or an error code if not.				
<code>transId</code>	The transaction ID of the operation.				

paramP	<p>The function ID of the function for which you are testing. For example, if you call <code>TelIsCgfGetSmsCenterSupported</code>, the value of this field is <code>kTelCgfGetSmsCenterMessage</code>.</p>
functionId	<p>The function ID value for each function is described in the documentation for the function.</p> <p><code>kTelUrqIsFunctionSupportedMessage</code></p>
<b>Comments</b>	<p>This is a family of synchronous macros that test if a specific function is available in the current environment.</p> <p>To use the macro, substitute a function name for the <i>&lt;FunctionName&gt;</i> portion of the macro name. You can substitute any Telephony Manager function name; for a complete list of the Telephony Manager functions, see “<a href="#">Summary of Telephony Manager</a>” on page 220 in <i>Palm OS Programmer’s Companion</i>, vol. II, <i>Communications</i>.</p> <p>For example, to determine if the <a href="#">TelNwkGetSignalLevel()</a> function is available in the current environment, call the <code>TelIsNwkGetSignalLevelSupported</code> macro.</p> <hr/> <p><b>NOTE:</b> A service set can be available without all of its functions being available. Thus, if the <a href="#">TelIs&lt;ServiceSet&gt;Available()</a> macro returns <code>true</code> for a specific service set, you know that the service set is available, but you need to call <a href="#">TelIs&lt;FunctionName&gt;Supported()</a> to determine if a specific function is available.</p> <hr/> <p>This macro corresponds to the <code>kTelUrqIsFunctionSupportedMessage</code> function ID value.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelIs&lt;ServiceSet&gt;Available()</a>

## Telephony Basic Services

*Tells<ServiceSet>Available*

---

### Tells<ServiceSet>Available Macros

<b>Purpose</b>	Determines if the specified service set is available.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>#define Tells&lt;ServiceSet&gt;Available     (iRefnum, iAppId, ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td>The service ID of the service set for which you are testing. For example, if you call <code>TelIsCfgServiceAvailable</code>, the value of this field is <code>kTelCfgServiceId</code>.</td></tr></table> <p>The service IDs are described in <a href="#">Service Set Constants</a>.</p> <table><tr><td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	The service ID of the service set for which you are testing. For example, if you call <code>TelIsCfgServiceAvailable</code> , the value of this field is <code>kTelCfgServiceId</code> .	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	The service ID of the service set for which you are testing. For example, if you call <code>TelIsCfgServiceAvailable</code> , the value of this field is <code>kTelCfgServiceId</code> .								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								

**Comments** This is a family of synchronous macros that test if a specific service set is available. You must call the appropriate set availability function before calling a function in the set.

---

**NOTE:** A service set can be available without all of its functions being available. You can use this macro to determine the availability of a specific service set, which you might use to determine the configuration of your applications' user interface. To test if a specific function is supported, use the [TellIs<FunctionName>Supported\(\)](#) macro.

---

You can call these specific macros to determine if the service set is available:

- [TellIsCfgServiceAvailable\(\)](#) to determine if the configuration service set is available.
- [TellIsDtcServiceAvailable\(\)](#) to determine if the data calls service set is available.
- [TellIsEmcServiceAvailable\(\)](#) to determine if the emergency calls service set is available.
- [TellIsInfServiceAvailable\(\)](#) to determine if the information service set is available.
- [TellIsNwkServiceAvailable\(\)](#) to determine if the network service set is available.
- [TellIsOemServiceAvailable\(\)](#) to determine if the OEM service set is available.
- [TellIsPhbServiceAvailable\(\)](#) to determine if the phone book service set is available.
- [TellIsPowServiceAvailable\(\)](#) to determine if the power service set is available.
- [TellIsSmsServiceAvailable\(\)](#) to determine if the SMS service set is available.
- [TellIsSndServiceAvailable\(\)](#) to determine if the sound service set is available.
- [TellIsSpcServiceAvailable\(\)](#) to determine if the speech calls service set is available.

## Telephony Basic Services

*TellIs<ServiceSet>Available*

---

- [TelIsStyServiceAvailable\(\)](#) to determine if the security service set is available.

Each of these macros corresponds to the kTelUrqIsServiceSupportedMessage function ID value.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported\(\)](#)

# Telephony Security and Configuration

---

This chapter describes the telephony security and configuration service sets of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Security and Configuration Data Structures](#)
- [Telephony Security and Configuration Constants](#)
- [Telephony Security and Configuration Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Security and Configuration Data Structures

This section describes the data structures used with the telephony security and configuration service sets portion of the telephony API.

### TelCfgGetPhoneNumberType Struct

**Purpose** The [TelCfgGetPhoneNumber\(\)](#) function uses a TelCfgGetPhoneNumberType structure to retrieve the connected phone dial number.

## Telephony Security and Configuration

### *TelCfgGetSmsCenterType*

---

**Prototype**    `typedef struct _TelCfgGetPhoneNumberType`  
                  `UInt8     size;`  
                  `Char*     value;`  
                  `} TelCfgGetPhoneNumberType`

#### Field Descriptions

↔            `size`                    The size of the value buffer.

When the structure is used as an input parameter, this is the allocated size, in bytes, of the value buffer.

Upon return, this is the actual size of the string, including the null terminator character. If the value buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

←            `value`                    A buffer into which the dial number is stored.

Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

## TelCfgGetSmsCenterType Struct

**Purpose**        The [TelCfgGetSmsCenter\(\)](#) function uses a `TelCfgGetSmsCenterType` structure to retrieve the SMS service center dial number.

**Prototype**    `typedef struct _TelCfgGetSmsCenterType`  
                  `UInt8     size;`  
                  `Char*     value;`  
                  `} TelCfgGetSmsCenterType`

### Field Descriptions

↔	size	<p>The size of the value buffer.</p> <p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the value buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the value buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
←	value	<p>A buffer into which the dial number is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.</p>

### TelStyChangeAuthenticationType Struct

**Purpose** You use the `TelStyChangeAuthenticationType` to change an authentication code with the [TelStyChangeAuthenticationCode\(\)](#) function.

**Prototype**

```
typedef struct _TelStyChangeAuthenticationType
{
    UInt    codeId;
    Char*   oldCode;
    Char*   newCode;
} TelStyChangeAuthenticationType
```

## Telephony Security and Configuration

### *Telephony Security and Configuration Constants*

---

#### Field Descriptions

→	<code>codeId</code>	The ID of the authentication code to change.
→	<code>oldCode</code>	The previous value of the code.
→	<code>newCode</code>	The new value of the code.

## Telephony Security and Configuration Constants

This section describes the constants used with the telephony security and configuration service sets of the telephony API.

### Authentication State Constants

The authentication state constants describe the current authentication state of the mobile unit connection.

Constant	Value	Description
<code>kTelStyReady</code>	0	No additional security information is expected.
<code>kTelStyPin1CodeId</code>	1	The PIN1 code is expected.
<code>kTelStyPin2CodeId</code>	2	The PIN2 code is expected.
<code>kTelStyPuk1CodeId</code>	3	The PUK1 code is expected.
<code>kTelStyPuk2CodeId</code>	4	The PUK2 code is expected.

Constant	Value	Description
kTelStyPhoneToSimCodeId	5	The phone-to-SIM code is expected.
kTelStyFirstOemCodeId	6	An OEM code is expected.
<p>The constant <code>kTelStyFirstOemCodeId</code> specifies the first OEM authentication code. You can specify additional OEM codes by incrementing this value. For example, to specify the third OEM authentication code, use the following:</p> <pre>kTelStyFirstOemCodeId+2</pre>		

## Telephony Security and Configuration Functions

This section describes the data structures used with the telephony security and configuration service sets portion of the telephony API.

### TelCfgGetPhoneNumber Function

<b>Purpose</b>	Retrieve the connected telephone number.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelCfgGetPhoneNumber(UInt16 iRefnum,     TelAppID iAppId,     TelCfgGetPhoneNumberType* ioParamP,     UInt16* ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i> A pointer to a <a href="#">TelCfgGetPhoneNumberType</a> structure that is filled in with the dial telephone number.</p>

## Telephony Security and Configuration

### *TelCfgGetPhoneNumber*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelCfgGetPhoneNumberType</a> structure passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelCfgGetPhoneNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The connected dial telephone number is stored into the `value` field of the [TelCfgGetPhoneNumberType](#) structure referenced by `ioParamP`. If the `value` field buffer is too small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete telephone number.

Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelCfgSetSmsCenter\(\)](#), [TelSmsSendMessage\(\)](#)

## TelCfgGetSmsCenter Function

<b>Purpose</b>	Retrieve the SMS service center dial telephone number.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelCfgGetSmsCenter(UInt16 iRefnum,                         TelAppID iAppId,                         TelCfgGetSmsCenterType* ioParamP,                         UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>↔ <i>ioParamP</i>  A pointer to a <a href="#">TelCfgGetSmsCenterType</a> structure that is filled in with the dial telephone number.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.   If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the <a href="#">TelCfgGetSmsCenterType</a> structure passed to this function in the <code>ioParamP</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelCfgGetSmsCenterMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the <a href="#">TelCfgGetSmsCenterType</a> structure passed to this function in the <code>ioParamP</code> parameter.	<code>functionId</code>	<code>kTelCfgGetSmsCenterMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the <a href="#">TelCfgGetSmsCenterType</a> structure passed to this function in the <code>ioParamP</code> parameter.								
<code>functionId</code>	<code>kTelCfgGetSmsCenterMessage</code>								

## Telephony Security and Configuration

### *TelCfgSetSmsCenter*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** The service center dial telephone number is stored into the `value` field of the [TelCfgGetSmsCenterType](#) structure referenced by `ioParamP`. If the `value` field buffer is too small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete telephone number.

Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelCfgSetSmsCenter\(\)](#), [TelSmsSendMessage\(\)](#)

## TelCfgSetSmsCenter Function

**Purpose** Set the SMS service center dial telephone number.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelCfgSetSmsCenter(UInt16 iRefnum,
                        TelAppID iAppId, const Char* iDialNumberP,
                        UInt16* ioTransIdP)
```

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iDialNumberP*  
A pointer to the null-terminated dial telephone number string for the SMS service center.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the string passed to this function in the <code>iDialNumberP</code> parameter.
<code>functionId</code>	<code>kTelCfgSetSmsCenterMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `iDialNumberP` remains in memory until the asynchronous call completes.

---

### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable\(\)](#) macro.

### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

### **See Also**

[TelCfgGetSmsCenter\(\)](#), [TelSmsSendMessage\(\)](#)

## TelStyChangeAuthenticationCode Function

**Purpose** Change the value of an authentication code. Note that you can only use this function with GSM networks.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err`  
`TelStyChangeAuthenticationCode (UInt16 iRefnum,`  
`TelAppID iAppId,`  
`TelStyChangeAuthenticationType* iParamP,`  
`UInt16* ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iParamP*  
A pointer to a [TelStyChangeAuthenticationType](#) structure that contains the old and new authentication code values.
- ↔ *ioTransIdP*  
Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`    `errNone` upon success or an error code upon failure.

`transId`        The transaction ID of the operation.

`paramP` Points to the [TelStyChangeAuthenticationType](#) structure passed to this function in the `iParamP` parameter.

`functionId` `kTelStyChangeAuthenticationCodeMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelStyEnterAuthenticationCode\(\)](#)

## TelStyEnterAuthenticationCode Function

**Purpose** Enter the authentication code for which the phone is currently waiting. Note that you can only use this function with GSM networks.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelStyEnterAuthenticationCode(UInt16 iRefnum, TelAppID iAppId, const Char* iCodeP, UInt16* ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iCodeP*  
A pointer to the null-terminated authentication code string to send to the phone.

## Telephony Security and Configuration

### *TelStyEnterAuthenticationCode*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the string passed to this function in the <code>iCodeP</code> parameter.
<code>functionId</code>	<code>kTelStyEnterAuthenticationCodeMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the string referenced by `iCodeP` remains in memory until the asynchronous call completes.

---

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelStyChangeAuthenticationCode\(\)](#),  
[TelStyGetAuthenticationState\(\)](#)

## TelStyGetAuthenticationState Function

<b>Purpose</b>	Returns the current state of user authentication.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelStyGetAuthenticationState(UInt16 iRefnum,     TelAppID iAppId, UInt8* oStateP,     UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i> The telephony manager library reference number.</p> <p>→ <i>iAppId</i> The telephone application attachment identifier for your application.</p> <p>← <i>oStateP</i> A pointer to an unsigned byte value. Upon return, this is the authentication state, which is one of the <a href="#">Authentication State Constants</a>.</p> <p>↔ <i>ioTransIdP</i> Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td>Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.</td></tr><tr><td><code>functionId</code></td><td><code>kTelStyGetAuthenticationStateMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.	<code>functionId</code>	<code>kTelStyGetAuthenticationStateMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.								
<code>functionId</code>	<code>kTelStyGetAuthenticationStateMessage</code>								

## Telephony Security and Configuration

### *TelStyGetAuthenticationState*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oStateP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelStyEnterAuthenticationCode\(\)](#)

# Telephony Network

---

This chapter describes the telephony network service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Network Data Structures](#)
- [Telephony Network Constants](#)
- [Telephony Network Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Network Data Structures

This section describes the data structures used with the telephony network service set portion of the telephony API.

### TelNwkGetLocationType Struct

**Purpose** You use the `TelNwkGetLocationType` structure with the [TelNwkGetLocation\(\)](#) function to retrieve information about the location of the phone.

**Prototype**

```
typedef struct _TelNwkGetLocationType
{
    Char*    value;
    UInt16   size;
} TelNwkGetLocationType
```

## Telephony Network

### *TelNwkGetNetworkNameType*

---

#### Field Descriptions

←	value	<p>A buffer into which the current location string is stored. The format of this string is network-dependent.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
↔	size	<p>The size of the <code>value</code> string. When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>value</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the <code>value</code> buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>

#### TelNwkGetNetworkNameType Struct

**Purpose** You use the `TelNwkGetNetworkNameType` structure with the [`TelNwkGetNetworkName\(\)`](#) function to retrieve the name of the specified, registered network.

**Prototype**

```
typedef struct _TelNwkGetNetworkNameType
{
    UInt32    id;
    Char*     value;
    UInt16    size;
} TelNwkGetNetworkNameType
```

### Field Descriptions

→	id	The network ID.
←	value	A null-terminated string buffer into which the network name is stored.
		Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.
↔	size	The size of the value string. When the structure is used as an input parameter, this is the allocated length, in bytes, of the value buffer.
		Upon return, this is the actual size of the string, including the null terminator character. If the value buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.

### TelNwkGetNetworksType Struct

**Purpose** You use the `TelNwkGetNetworksType` structure with the [TelNwkGetNetworks\(\)](#) function to retrieve the number of registered networks.

**Prototype**

```
typedef struct _TelNwkGetNetworksType
{
    UInt32*   networkIdP;
    UInt8     size;
} TelNwkGetNetworksType
```

#### Field Descriptions

←	<code>networkIdP</code>	An array into which the retrieved network IDs are stored.
		Note that if this buffer is too small to contain all of the available IDs, the data is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.
↔	<code>size</code>	When the structure is use as an input value, this is the allocated size, in elements, of the <code>networkIdP</code> array.  When the structure is used as a return value, this is the number of network IDs that are available. If the the <code>networkP</code> buffer is too small to contain all of the retrieved IDs, this field is assigned the entire number of available IDs, and the function using this structure generates a <code>telErrBufferSize</code> error

## Telephony Network Constants

This section describes the constants used with the telephony network service set of the telephony API, which include the following constant types:

- [Network Type Constants](#)
- [Network Search Mode Constants](#)

### Network Type Constants

The network type constants describe the type of network connection.

Constant	Value	Description
kTelNwkCDMA	0	A CDMA network.
kTelNwkGSM	1	A GSM network.
kTelNwkTDMA	2	A TDMA network.
kTelNwkPDC	3	A PDC network.

## Network Search Mode Constants

The network search mode constants describe the search mode used to find a network.

Constant	Value	Description
kTelNwkManualSearch	0	Manual network searching.
kTelNwkAutomaticSearch	1	Automatic network searching.

## Telephony Network Functions

This section describes the data structures used with the telephony network service set portion of the telephony API.

### TelNwkGetLocation Function

<b>Purpose</b>	Retrieve information about the location of the mobile unit.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelNwkGetLocation(UInt16 iRefnum,     TelAppID iAppId,     TelNwkGetLocationType* ioParamP,     UInt16* ioTransIdP)</pre>
<b>Parameters</b>	<p>→ <i>iRefnum</i></p> <p>The telephony manager library reference number.</p>

## Telephony Network

### *TelNwkGetLocation*

---

→ *iAppId*

The telephone application attachment identifier for your application.

↔ *ioParamP*

A pointer to a [TelNwkGetLocationType](#) structure.

On input, the `size` field of this structure specifies the allocated size of the value buffer. Upon return, the `size` field specifies the actual size of the location string, even if it was truncated to fit into the buffer.

↔ *ioTransIdP*

Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelNwkGetLocationType</a> passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelNwkGetLocationMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

The location information string is stored into the `value` field of the [TelNwkGetLocationType](#) structure referenced by `ioParamP`. If the value buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field

of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkGetNetworkName Function

**Purpose** Returns the name of a registered network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkGetNetworkName (UInt16 iRefnum,  
 TelAppID iAppId,  
 TelNwkGetNetworkNameType* ioParamP,  
 UInt16* ioTransIdP)`

**Parameters**

- *iRefnum*  
 The telephony manager library reference number.
- *iAppId*  
 The telephone application attachment identifier for your application.
- ↔ *ioParamP*  
 A pointer to a [TelNwkGetNetworkNameType](#) structure that stores the network name.  
  
 On input, the `size` field of this structure specifies the allocated size of the value buffer. Upon return, the `size` field specifies the actual size of the name string, even if it was truncated to fit into the buffer.
- ↔ *ioTransIdP*  
 Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
 If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

## Telephony Network

### *TelNwkGetNetworkName*

---

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelNwkGetNetworkNameType</a> passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelNwkGetNetworkNameMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### Comments

The network name string is stored into the `value` field of the structure. If the `value` field buffer in the [TelNwkGetNetworkNameType](#) structure is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field is always updated to contain the actual size of the complete string.

The string that is returned in the `value` field of the structure referenced by `ioParamP` is network dependent.

On a GSM network, the result string is compliant with the AT 07.07 European Telecommunications Standards Institute (ETSI) standard for COPS and CREG commands. The result string contains the following elements:

- The network type, as returned by the [TelNwkGetNetworkType\(\)](#) function, and followed by a semicolon ( ';' ) character.
- The network operator, using the following syntax:

`<area code> ';' <network registration>`

The `<area code>` value is the value retrieved by issuing the `AT+CREG?` command.

The `<network registration>` value is the value retrieved by issuing the `AT+CREG?` command.

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelNwkGetNetworks\(\)](#), [TelNwkGetSelectedNetwork\(\)](#)

## TelNwkGetNetworks Function

**Purpose**            Retrieves information about the registered networks.

**Declared In**      `TelephonyMgr.h`

**Prototype**        `Err TelNwkGetNetworks (UInt16 iRefnum,  
                          TelAppID iAppId,  
                          TelNwkGetNetworksType* ioParamP,  
                          UInt16* ioTransIdP)`

**Parameters**       $\rightarrow$  *iRefnum*  
                          The telephony manager library reference number.

$\rightarrow$  *iAppId*  
                          The telephone application attachment identifier for your application.

$\leftrightarrow$  *ioParamP*  
                          A pointer to a [TelNwkGetNetworksType](#) structure that stores the network IDs. On input, the `size` field of this structure contains the size, in elements, of the `networkIdP` array field.

Upon return, the `networkIdP` array contains the IDs of the registered networks, and the `size` field contains the number of IDs in the array.

## Telephony Network

### *TelNwkGetNetworks*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelNwkGetNetworksType</a> passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelNwkGetNetworkCountMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelNwkGetNetworkName\(\)](#), [TelNwkGetNetworks\(\)](#)

## TelNwkGetNetworkType Function

<b>Purpose</b>	Retrieve the type of the selected network.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelNwkGetNetworkType (UInt16 iRefnum,                           TelAppID iAppId, UInt8* oTypeP,                           UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>← <i>oTypeP</i>  A pointer to an unsigned byte value. Upon return, this is the network type. This is one of <a href="#">Network Type Constants</a>.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the unsigned integer value passed to this function in the <code>oTypeP</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelNwkGetNetworkTypeMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oTypeP</code> parameter.	<code>functionId</code>	<code>kTelNwkGetNetworkTypeMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.

<code>functionId</code>	<code>kTelNwkGetNetworkTypeMessage</code>								

## Telephony Network

### *TelNwkGetSearchMode*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value you pass for the `oTypeP` parameter remains in memory until the asynchronous call completes.

---

- Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkGetSearchMode Function

- Purpose** Returns the current network search mode.
- Declared In** `TelephonyMgr.h`
- Prototype**  
`Err TelNwkGetSearchMode(UInt16 iRefnum,  
TelAppID iAppId, UInt8* oModeP,  
UInt16* ioTransIdP)`
- Parameters**
- *iRefnum*  
The telephony manager library reference number.
  - *iAppId*  
The telephone application attachment identifier for your application.
  - ← *oModeP*  
A pointer to an unsigned byte value. Upon return, this is the type of search mode that is currently being used. This is one of the [Network Search Mode Constants](#).
  - ↔ *ioTransIdP*  
Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
- Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.
- Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the oModeP parameter.
functionId	kTelNwkGetSearchModeMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oModeP remains in memory until the asynchronous call completes.

---

<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsNwkServiceAvailable()</a> macro.
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelNwkSetSearchMode()</a>

## TelNwkGetSelectedNetwork Function

<b>Purpose</b>	Retrieve the network identifier of the currently selected network.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelNwkGetSelectedNetwork(UInt16 iRefnum, TelAppID iAppId, UInt32* oNetworkIdP, UInt16* ioTransIdP)
<b>Parameters</b>	<p>→ <i>iRefnum</i>              The telephony manager library reference number.</p> <p>→ <i>iAppId</i>              The telephone application attachment identifier for your application.</p> <p>← <i>oNetworkIdP</i>              A pointer to an unsigned integer value. Upon return, this is the identifier of the currently selected network.</p>

## Telephony Network

### *TelNwkGetSelectedNetwork*

---

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oNetworkIdP</code> parameter.
<code>functionId</code>	<code>kTelNwkGetSelectedNetworkMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oNetworkP` remains in memory until the asynchronous call completes.

---

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

[TelNwkGetNetworkName\(\)](#), [TelNwkGetNetworks\(\)](#), [TelNwkSelectNetwork\(\)](#)

## TelNwkGetSignalLevel Function

<b>Purpose</b>	Retrieve the selected network carrier signal level.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelNwkGetSignalLevel(UInt16 iRefnum,                         TelAppID iAppId, UInt8* oSignalP,                         UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<p>→ <i>iRefnum</i>  The telephony manager library reference number.</p> <p>→ <i>iAppId</i>  The telephone application attachment identifier for your application.</p> <p>← <i>oSignalP</i>  A pointer to an unsigned byte value. Upon return, this is an indication of the signal level in decibels per milliwatt (dBm). The values are explained in the Comments section.</p> <p>↔ <i>ioTransIdP</i>  Set the value of this parameter to NULL to cause the function to execute synchronously.</p> <p>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table> <tr> <td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr> <tr> <td><code>transId</code></td><td>The transaction ID of the operation.</td></tr> <tr> <td><code>paramP</code></td><td>Points to the unsigned integer value passed to this function in the <code>oSignalP</code> parameter.</td></tr> <tr> <td><code>functionId</code></td><td><code>kTelNwkGetSignalLevelMessage</code></td></tr> </table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oSignalP</code> parameter.	<code>functionId</code>	<code>kTelNwkGetSignalLevelMessage</code>
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	Points to the unsigned integer value passed to this function in the <code>oSignalP</code> parameter.								
<code>functionId</code>	<code>kTelNwkGetSignalLevelMessage</code>								

## Telephony Network

### *TelNwkSelectNetwork*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oSignalP` remains in memory until the asynchronous call completes.

---

**Comments** This function sets the value of the variable referenced by `oSignalP` to an integer value that indicates the signal strength in dBm.

The following table describes the signal strength values.

Signal level value	dBm value
0	≤ 113 dBm
1	111 dBm
2 to 30	109 dBm to 53 dBm
31	≥ 51 dBm
99	unknown or undetectable

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkSelectNetwork Function

**Purpose** Select a network to use from among the set of registered networks.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkSelectNetwork(UInt16 iRefnum,  
TelAppID iAppId, UInt32 iNetworkId,  
UInt16* ioTransIdP)`

**Parameters**

- *iRefnum*  
The telephony manager library reference number.
- *iAppId*  
The telephone application attachment identifier for your application.
- *iNetworkId*  
The identifier of the network to select.

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the network unsigned integer value passed to this function in the `iNetworkId` parameter.

`functionId`      `kTelNwkSelectNetworkMessage`

**Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelNwkGetNetworkName\(\)](#), [TelNwkGetNetworks\(\)](#), [TelNwkGetSelectedNetwork\(\)](#)

## TelNwkSetSearchMode Function

**Purpose** Sets the search mode used to find a network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkSetSearchMode(UInt16 iRefnum, TelAppID iAppId, UInt8 iMode, UInt16* ioTransIdP)`

**Parameters** → *iRefnum*  
The telephony manager library reference number.

## Telephony Network

### *TelNwkSetSearchMode*

---

→ *iAppId*

The telephone application attachment identifier for your application.

→ *iMode*

The search mode to use. This must be one of the [Network Search Mode Constants](#).

↔ *ioTransIdP*

Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### **Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

#### **Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`          Points to the unsigned integer value passed to this function in the `iMode` parameter.

`functionId`      `kTelNwkSetSearchModeMessage`

#### **Comments**

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable\(\)](#) macro.

#### **Compatibility**

Implemented only if [4.0 New Feature Set](#) is present.

#### **See Also**

# Telephony Calls

---

This chapter describes the telephony calls service sets of the telephony API, which include:

- The data calls service set
- The emergency calls service set
- The speech (voice) calls service set

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Calls Data Structures](#)
- [Telephony Calls Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Calls Data Structures

This section describes the data structures used with the telephony calls service sets portion of the telephony manager API.

### TelDtcCallNumberType Struct

**Purpose** The [TelDtcCallNumber\(\)](#) function uses the `TelDataCallNumberType` structure to specify information about the telephone number to call.

**Prototype**

```
typedef struct _TelDtcCallNumberType
{
    char        *dialNumberP;
    UInt8       lineId;
```

## Telephony Calls

### *TelDtcReceiveDataType*

---

```
} TelDtcCallNumberType
```

#### Field Descriptions

- |   |             |  |
|---|-------------|--|
| → | dialNumberP | The telephone number to dial.  |
| ← | lineId      | Upon return from the <a href="#">TelDtcCallNumber()</a> function, this is the ID of the data line that was established for the telephone call. |

## TelDtcReceiveDataType Struct

**Purpose** The [TelDtcReceiveData\(\)](#) function uses a `TelDtcReceiveDataType` structure to receive data from an open data line.

**Prototype**

```
typedef struct _TelDtcReceiveDataType
{
    UInt8      *data;
    UInt32     size;
    UInt32     timeout;
} TelDtcReceiveDataType
```

#### Field Descriptions

- |   |      |   |
|---|------|---|
| ← | data | A buffer into which the data is stored. |
|---|------|---|

Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a `telErrBufferSize` error.

↔	size	When the structure is used as an input parameter, this is the allocated size, in bytes, of the data buffer.
		Upon return, this is the actual number of bytes of data that was retrieved. If the data buffer is too small to contain all of the retrieved data, the function using this structure generates a telErrBufferSize error.
→	timeout	The number of milliseconds to wait before timing out.

## TelDtcSendDataType Struct

**Purpose** The [TelDtcReceiveData\(\)](#) function uses a TelDtcSendDataType structure to send data to an open data line.

**Prototype**

```
typedef struct _TelDtcSendDataType
{
    UInt8      *data;
    UInt32     size;
} TelDtcSendDataType
```

### Field Descriptions

→	data	A pointer to the data to send.
→	size	The number of bytes of data in the data buffer.

## TelEmcGetNumberType Struct

**Purpose** The [TelEmcGetNumber\(\)](#) function uses a TelEmcGetNumberType structure to retrieve an emergency dial telephone number.

**Prototype**

```
typedef struct _TelEmcGetNumberType
{
    UInt8      index;
    UInt8      size;
    Char       *value;
} TelEmcGetNumberType
```

#### Field Descriptions

→	index	The index of the telephone number. This is a zero-based index.
↔	size	When the structure is used as an input parameter, this is the allocated size, in bytes, of the value buffer.

Upon return, this is the actual size of the string, including the null terminator character. If the value buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

←	value	A null-terminated string buffer into which the emergency dial telephone number is stored.
---	-------	---

Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a `telErrBufferSize` error.

#### TelEmcSetNumberType Struct

**Purpose** The [`TelEmcSetNumber\(\)`](#) function uses a `TelEmcNumberType` structure to set an emergency dial telephone number.

**Prototype**

```
typedef struct _TelEmcSetNumberType
{
    UInt8    index;
    Char     *value;
} TelEmcSetNumberType
```

### Field Descriptions

→	index	The index of the telephone number. This is a zero-based index.
→	value	The string value of the number to store as the <code>index</code> th entry.

## TelSpcGetCallerNumberType Struct

**Purpose** The [`TelSpcGetCallerNumber\(\)`](#) function uses a `TelSpcGetCallerNumberType` structure to retrieve an incoming telephone number.

**Prototype**

```
typedef struct _TelSpcGetCallerNumberType
{
    Char      *value;
    UInt8     size;
} TelSpcGetCallerNumberType
```

### Field Descriptions

←	value	A null-terminated string buffer into which the caller telephone number is stored.
---	-------	---

Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a `telErrBufferSize` error.

↔	size	When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>value</code> buffer.
---	------	---

Upon return, this is the actual size of the caller dial telephone number, including the null terminator character. If the `value` buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

### TelSpcPlayDTMFType Struct

**Purpose** The [TelSpcPlayDTMF\(\)](#) function uses a `TelSpcPlayDTMFType` structure to specify the qualities of the DTMF (dual-tone, multi-frequency) sound sent by the phone to the network or remote, connected equipment.

**Prototype**

```
typedef struct _TelSpcPlayDTMFType
    UInt8    keyTone;
    UInt32   duration;
